Set-AWSCredentials -AccessKey key_name -SecretKey key_name
```

2. Execute the following command to set the Region for your PowerShell session. The example uses the `us-east-2` Region.

```
Set-DefaultAWSRegion -Region us-east-2
```

3. Download the [CreateVssSnapshotAdvancedScript.zip](#) file and extract the file contents.
4. Open `CreateVssSnapshotAdvancedScript.ps1` in a text editor, edit the sample call at the bottom of the script with a valid EC2 instance ID, snapshot description, and desired tag values, and then run the script from PowerShell.

If successful, the command populates the list of EBS snapshots with the new snapshots. You can locate these snapshots in the list of EBS snapshots by searching for the tags you specified, or by searching for `AppConsistent`. If the command execution failed, view the command output for details about why the execution failed. If the command was successfully completed, but a specific volume backup failed, you can troubleshoot the failure in the list of EBS volumes.

Troubleshoot VSS-enabled EBS snapshots

General: Checking the log files

If you experience problems or receive error messages when creating VSS-enabled EBS snapshots, you can view the command output in the Systems Manager console. You can also view the following logs:

- %ProgramData%\Amazon\SSM\InstanceData\InstanceID\document\orchestration\SSMCommandID\awsrunPowerShellScript\runPowerShellScript\stdout
- %ProgramData%\Amazon\SSM\InstanceData\InstanceID\document\orchestration\SSMCommandID\awsrunPowerShellScript\runPowerShellScript\stderr

You can also open the Event Viewer Windows application and choose **Windows Logs, Application** to view additional logs. To see events specifically from the EC2 Windows VSS Provider and the Volume Shadow Copy Service, filter by **Source** on the terms **Ec2VssSoftwareProvider** and **VSS**.

Error: Thaw pipe connection timed out, error on thaw, timeout waiting for VSS Freeze, or other timeout errors

The EC2 Windows VSS Provider might time out due to activity or services on the instance preventing VSS-enabled snapshots from proceeding in a timely manner. The Windows VSS Framework provides a non-configurable 10-second window during which communication to the file system is paused. During this time, AWSEC2-CreateVssSnapshot snapshots your volumes.

The following items can cause the EC2 Windows VSS Provider to run into time limits during a snapshot:

- Excessive I/O to a volume
- Slow responsiveness of the EC2 API on the instance
- Fragmented volumes
- Incompatibility with some antivirus software
- Issues with a VSS Application writer
- When Module Logging is enabled for a large number of PowerShell modules, that can cause PowerShell scripts to run slowly

Usually, when running into time limits with the AWSEC2-CreateVssSnapshot command, the cause is related to the workload on the instance being too high at the time of backup. The following actions can help you take a successful snapshot:

- Retry the AWSEC2-CreateVssSnapshot command to see if the snapshot attempt is successful. If retrying succeeds in some cases, reducing the instance load might make snapshots more successful.
- Wait a while for the workload on the instance to decrease, and retry the AWSEC2-CreateVssSnapshot command. Alternatively, you can attempt snapshots when the instance is known to be under low stress.
- Attempt VSS snapshots when the antivirus software on the system is turned off. If this resolves the issue, refer to the antivirus software instructions and configure it to allow VSS snapshots.
- If there are a lot of EC2 API calls being made at the time of the snapshot, API throttling might cause the snapshots to take too long to start. Try taking snapshots again when there is less API activity in the account.
- Run the command `vssadmin list writers` in a shell and see if it reports any errors in the **Last error** field for any writers on the system. If any writers report a **time out** error, consider retrying snapshots when the instance is under less load.
- If one or more PowerShell modules have Group Policies that enable PowerShell module logging, try temporarily disabling the logging before you take a snapshot.

Error: Cannot invoke method. Method invocation is supported only on core types in this language mode.

You will encounter this error when the PowerShell language mode is not set to FullLanguage. The AWSEC2-CreateVssSnapshot and AWSEC2-ManageVssIo SSM documents require PowerShell to be configured to FullLanguage mode.

To verify the language mode, run the following command on the instance in a PowerShell console:

```
$ExecutionContext.SessionState.LanguageMode
```

For more information about language modes, see [about_Language_Modes](#) in the Microsoft documentation.

Restore volumes from VSS-enabled EBS snapshots

You can use the `RestoreVssSnapshotSampleScript.ps1` script to restore volumes on an instance from VSS-enabled EBS snapshots. This script performs the following tasks:

- Stops an instance
- Removes all existing drives from the instance (except the boot volume, if it was excluded)
- Creates new volumes from the snapshots
- Attaches the volumes to the instance by using the device ID tag on the snapshot
- Restarts the instance

Important

The following script detaches all volumes attached to an instance, and then creates new volumes from a snapshot. Make sure that you have properly backed-up the instance. The old volumes are not deleted. If you want, you can edit the script to delete the old volumes.

To restore volumes from VSS-enabled EBS snapshots

1. Open AWS Tools for Windows PowerShell and run the following command to specify your user access keys. Your user must either have administrative access for Amazon EC2 or it must have the required permissions granted. For more information, see [Setting Up AWS Systems Manager](#) in the [AWS Systems Manager User Guide](#).

```
Set-AWSCredentials -AccessKey key_name -SecretKey key_name
```

2. Run the following command to set the Region for your PowerShell session. The example uses the `us-east-2` Region.

```
Set-DefaultAWSRegion -Region us-east-2
```

3. Download the [RestoreVssSnapshotSampleScript.zip](#) file and extract the file contents.
4. Open [RestoreVssSnapshotSampleScript.zip](#) in a text editor and edit the sample call at the bottom of the script with a valid EC2 instance ID and EBS snapshot ID, and then run the script from PowerShell.

AWS VSS component package version history

The following table describes the released versions of the AWS VSS component package.

Version	Details	Release date
2.0.0	Added capability to the AWS VSS component to create snapshots and AMIs, which enables compatibility with PowerShell module logging, script block logging, and transcription features.	April 28, 2023
1.3.2.0	Fixed a case where installation failure is not reported correctly.	May 10, 2022
1.3.1.0	<ul style="list-style-type: none"> Fixed snapshots failing on domain controllers in relation to an NTDS VSS writer logging error. Fixed VSS agent error when uninstalling version 1.0 VSS provider. 	February 6, 2020
1.3.00	<ul style="list-style-type: none"> Improved logging by reducing unwanted verbosity. Fixed regionalization issues during installation. Fixed return codes for some provider registration error conditions. Fixed various installation issues. 	March 19, 2019
1.2.00	<ul style="list-style-type: none"> Added command line parameters -nw (no-writers) and -copy (copy-only) to agent. Fixed EventLog errors caused by improper memory allocation calls. 	November 15, 2018
1.1	Fixed AWS VSS components that were being used incorrectly as the default Windows Backup and Restore provider.	December 12, 2017
1.0	Initial release.	November 20, 2017

Delete an Amazon EBS snapshot

After you no longer need an Amazon EBS snapshot of a volume, you can delete it. Deleting a snapshot has no effect on the volume. Deleting a volume has no effect on the snapshots made from it.

Incremental snapshot deletion

If you make periodic snapshots of a volume, the snapshots are *incremental*. This means that only the blocks on the device that have changed after your most recent snapshot are saved in the new snapshot. Even though snapshots are saved incrementally, the snapshot deletion process is designed so that you need to retain only the most recent snapshot in order to create volumes.

If data was present on a volume held in an earlier snapshot or series of snapshots, and that data is subsequently deleted from the volume later on, the data is still considered to be unique data of the earlier snapshots. Unique data is only deleted from the sequence of snapshots if all snapshots that reference the unique data are deleted.

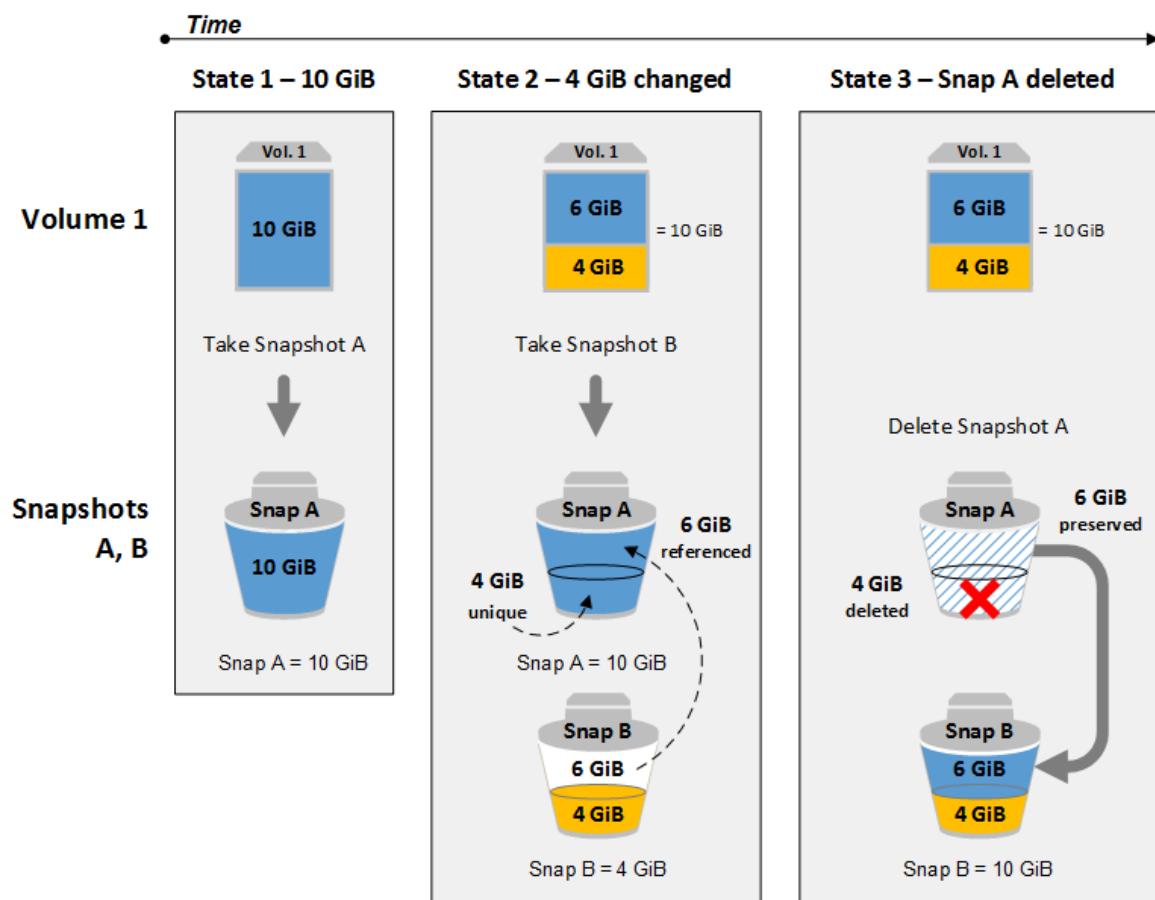

When you delete a snapshot, only the data that is referenced exclusively by that snapshot is removed. Unique data is only deleted if all of the snapshots that reference it are deleted. Deleting previous snapshots of a volume does not affect your ability to create volumes from later snapshots of that volume.

Deleting a snapshot might not reduce your organization's data storage costs. Other snapshots might reference that snapshot's data, and referenced data is always preserved. If you delete a snapshot containing data being used by a later snapshot, costs associated with the referenced data are allocated to the later snapshot. For more information about how snapshots store data, see [How snapshots work \(p. 1758\)](#) and the following example.

In the following diagram, Volume 1 is shown at three points in time. A snapshot has captured each of the first two states, and in the third, a snapshot has been deleted.

- In State 1, the volume has 10 GiB of data. Because Snap A is the first snapshot taken of the volume, the entire 10 GiB of data must be copied.
- In State 2, the volume still contains 10 GiB of data, but 4 GiB have changed. Snap B needs to copy and store only the 4 GiB that changed after Snap A was taken. The other 6 GiB of unchanged data, which are already copied and stored in Snap A, are referenced by Snap B rather than (again) copied. This is indicated by the dashed arrow.
- In state 3, the volume has not changed since State 2, but Snapshot A has been deleted. The 6 GiB of data stored in Snapshot A that were referenced by Snapshot B have now been moved to Snapshot B, as shown by the heavy arrow. As a result, you are still charged for storing 10 GiB of data; 6 GiB of unchanged data preserved from Snap A and 4 GiB of changed data from Snap B.

Deleting a snapshot with some of its data referenced by another snapshot

Considerations

The following considerations apply to deleting snapshots:

- You can't delete a snapshot of the root device of an EBS volume used by a registered AMI. You must first deregister the AMI before you can delete the snapshot. For more information, see [Deregister your AMI \(p. 185\)](#).

- You can't delete a snapshot that is managed by the AWS Backup service using Amazon EC2. Instead, use AWS Backup to delete the corresponding recovery points in the backup vault. For more information, see [Deleting backups](#) in the *AWS Backup Developer Guide*.
- You can create, retain, and delete snapshots manually, or you can use Amazon Data Lifecycle Manager to manage your snapshots for you. For more information, see [Amazon Data Lifecycle Manager \(p. 1859\)](#).
- Although you can delete a snapshot that is still in progress, the snapshot must complete before the deletion takes effect. This might take a long time. If you are also at your concurrent snapshot limit, and you attempt to take an additional snapshot, you might get a `ConcurrentSnapshotLimitExceeded` error. For more information, see the [Service Quotas](#) for Amazon EBS in the *Amazon Web Services General Reference*.
- If you delete a snapshot that matches an Recycle Bin retention rule, the snapshot is retained in the Recycle Bin instead of being immediately deleted. For more information, see [Recycle Bin \(p. 2045\)](#).

Delete a snapshot

To delete a snapshot, use one of the following methods.

Console

To delete a snapshot using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the snapshot to delete, and then choose **Actions, Delete snapshot**.
4. Choose **Delete**.

AWS CLI

To delete a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [delete-snapshot](#) (AWS CLI)
- [Remove-EC2Snapshot](#) (AWS Tools for Windows PowerShell)

Delete a multi-volume snapshot

To delete multi-volume snapshots, retrieve all of the snapshots for your multi-volume snapshot set using the tag you applied to the set when you created the snapshots. Then, delete the snapshots individually.

You will not be prevented from deleting individual snapshots in the multi-volume snapshot set. If you delete a snapshot while it is in the `Pending` state, only that snapshot is deleted. The other snapshots in the multi-volume snapshot set still complete successfully.

Copy an Amazon EBS snapshot

With Amazon EBS, you can create point-in-time snapshots of volumes, which we store for you in Amazon S3. After you create a snapshot and it has finished copying to Amazon S3 (when the snapshot status is completed), you can copy it from one AWS Region to another, or within the same Region. Amazon S3 server-side encryption (256-bit AES) protects a snapshot's data in transit during a copy operation. The snapshot copy receives an ID that is different from the ID of the original snapshot.

To copy multi-volume snapshots to another AWS Region, retrieve the snapshots using the tag you applied to the multi-volume snapshot set when you created it. Then individually copy the snapshots to another Region.

If you would like another account to be able to copy your snapshot, you must either modify the snapshot permissions to allow access to that account or make the snapshot public so that all AWS accounts can copy it. For more information, see [Share an Amazon EBS snapshot \(p. 1810\)](#).

For information about copying an Amazon RDS snapshot, see [Copying a DB Snapshot](#) in the *Amazon RDS User Guide*.

Use cases

- Geographic expansion: Launch your applications in a new AWS Region.
- Migration: Move an application to a new Region, to enable better availability and to minimize cost.
- Disaster recovery: Back up your data and logs across different geographical locations at regular intervals. In case of disaster, you can restore your applications using point-in-time backups stored in the secondary Region. This minimizes data loss and recovery time.
- Encryption: Encrypt a previously unencrypted snapshot, change the key with which the snapshot is encrypted, or create a copy that you own in order to create a volume from it (for encrypted snapshots that have been shared with you).
- Data retention and auditing requirements: Copy your encrypted EBS snapshots from one AWS account to another to preserve data logs or other files for auditing or data retention. Using a different account helps prevent accidental snapshot deletions, and protects you if your main AWS account is compromised.

Contents

- [Prerequisites \(p. 1782\)](#)
- [Considerations \(p. 1783\)](#)
- [Pricing \(p. 1783\)](#)
- [Incremental snapshot copying \(p. 1783\)](#)
- [Encryption and snapshot copying \(p. 1784\)](#)
- [Copy a snapshot \(p. 1784\)](#)

Prerequisites

- You can copy any accessible snapshots that have a completed status, including shared snapshots and snapshots that you have created.
- You can copy AWS Marketplace, VM Import/Export, and Storage Gateway snapshots, but you must verify that the snapshot is supported in the destination Region.
- To copy an encrypted snapshot, your user must have the following permissions to use Amazon EBS encryption.
 - kms:DescribeKey
 - kms>CreateGrant
 - kms:GenerateDataKey
 - kms:ReEncrypt
 - kms:Decrypt
- To copy an encrypted snapshot shared from another AWS account, you must have permissions to use customer managed key that was used to encrypt the snapshot. For more information, see [Share a KMS key \(p. 1812\)](#).

Considerations

- There is a limit of 20 concurrent snapshot copy requests per destination Region. If you exceed this quota, you receive a `ResourceLimitExceeded` error. If you receive this error, wait for one or more of the copy requests to complete before making a new snapshot copy request.
- User-defined tags are not copied from the source snapshot to the new snapshot. You can add user-defined tags during or after the copy operation. For more information, see [Tag your Amazon EC2 resources \(p. 2085\)](#).
- Snapshots created by a snapshot copy operation have an arbitrary volume ID, such as `vol-ffff` or `vol-ffffffff`. These arbitrary volume IDs should not be used for any purpose.
- Resource-level permissions specified for the snapshot copy operation apply only to the new snapshot. You cannot specify resource-level permissions for the source snapshot. For an example, see [Example: Copying snapshots \(p. 1613\)](#).

Pricing

- For pricing information about copying snapshots across AWS Regions and accounts, see [Amazon EBS Pricing](#).
- If you copy a snapshot and encrypt it to a new KMS key, a complete (non-incremental) copy is created. This results in additional storage costs.
- If you copy a snapshot to a new Region, a complete (non-incremental) copy is created. This results in additional storage costs. Subsequent copies of the same snapshot are incremental.
- The first snapshot copy from a snapshot in the same account and the same Region using the same customer managed key will be a complete (non-incremental) copy. This results in additional storage costs. Subsequent copies of the same snapshot are incremental.

Incremental snapshot copying

Whether a snapshot copy is incremental is determined by the most recently completed snapshot copy. When you copy a snapshot across Regions or accounts, the copy is an incremental copy if the following conditions are met:

- The snapshot was copied to the destination Region or account previously.
- The most recent snapshot copy still exists in the destination Region or account.
- All copies of the snapshot in the destination Region or account are either unencrypted or were encrypted using the same KMS key.

If the most recent snapshot copy was deleted, the next copy is a full copy, not an incremental copy. If a copy is still pending when you start another copy, the second copy starts only after the first copy finishes.

Snapshot copy operations within a single account and the same Region using a customer managed key will generate a complete (non-incremental) copy. Subsequent copies of the same snapshot are incremental.

Incremental snapshot copying reduces the time required to copy snapshots and saves on data transfer and storage costs by not duplicating data.

We recommend that you tag your snapshots with the volume ID and creation time so that you can keep track of the most recent snapshot copy of a volume in the destination Region or account.

To see whether your snapshot copies are incremental, check the [copySnapshot \(p. 1991\)](#) CloudWatch event.

Encryption and snapshot copying

When you copy a snapshot, you can encrypt the copy or you can specify a KMS key that is different than the original, and the resulting copied snapshot uses the new KMS key. However, changing the encryption status of a snapshot during a copy operation could result in a full (not incremental) copy, which might incur greater data transfer and storage charges. For more information, see [Incremental snapshot copying \(p. 1783\)](#).

To copy an encrypted snapshot shared from another AWS account, you must have permissions to use the snapshot and the customer managed key (CMK) that was used to encrypt the snapshot. When using an encrypted snapshot that was shared with you, we recommend that you re-encrypt the snapshot by copying it using a KMS key that you own. This protects you if the original KMS key is compromised, or if the owner revokes it, which could cause you to lose access to any encrypted volumes that you created using the snapshot. For more information, see [Share an Amazon EBS snapshot \(p. 1810\)](#).

You apply encryption to EBS snapshot copies by setting the `Encrypted` parameter to `true`. (The `Encrypted` parameter is optional if [encryption by default \(p. 1925\)](#) is enabled).

Optionally, you can use `KmsKeyId` to specify a custom key to use to encrypt the snapshot copy. (The `Encrypted` parameter must also be set to `true`, even if encryption by default is enabled.) If `KmsKeyId` is not specified, the key that is used for encryption depends on the encryption state of the source snapshot and its ownership.

The following table describes the encryption outcomes for each possible combination of settings when copying snapshots that you own and snapshots that are shared with you.

Encryption by default	Is Encrypted parameter set?	Source snapshot encryption status	Default (no KMS key specified)	Custom (KMS key specified)
Disabled	No	Unencrypted	Unencrypted	N/A
		Encrypted	Encrypted by AWS managed key	
	Yes	Unencrypted	Encrypted by default KMS key	Encrypted by specified KMS key**
		Encrypted	Encrypted by default KMS key	
Enabled	No	Unencrypted	Encrypted by default KMS key	N/A
		Encrypted	Encrypted by default KMS key	
	Yes	Unencrypted	Encrypted by default KMS key	Encrypted by specified KMS key**
		Encrypted	Encrypted by default KMS key	

** This is the KMS key specified in the copy snapshot action. This KMS key is used instead of the default KMS key for the account and Region.

Copy a snapshot

To copy a snapshot, use one of the following methods.

Console

To copy a snapshot using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the snapshot to copy, and then choose **Actions**, **Copy snapshot**.
4. For **Description**, enter a brief description for the snapshot copy.

By default, the description includes information about the source snapshot so that you can identify a copy from the original. You can change this description as needed.

5. For **Destination Region**, select the Region in which to create the snapshot copy.
6. Specify the encryption status for the snapshot copy.

If the source snapshot is encrypted, or if your account is enabled for [encryption by default \(p. 1925\)](#), then the snapshot copy is automatically encrypted and you can't change its encryption status.

If the source snapshot is unencrypted and your account is not enabled for encryption by default, encryption is optional. To encrypt the snapshot copy, for **Encryption**, select **Encrypt this snapshot**. Then, for **KMS key**, select the KMS key to use to encrypt the snapshot in the destination Region.

7. Choose **Copy snapshot**.

AWS CLI

To copy a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [copy-snapshot \(AWS CLI\)](#)
- [Copy-EC2Snapshot \(AWS Tools for Windows PowerShell\)](#)

To check for failure

If you attempt to copy an encrypted snapshot without having permissions to use the encryption key, the operation fails silently. The error state is not displayed in the console until you refresh the page. You can also check the state of the snapshot from the command line, as in the following example.

```
aws ec2 describe-snapshots --snapshot-id snap-0123abcd
```

If the copy failed because of insufficient key permissions, you see the following message: "StateMessage": "Given key ID is not accessible".

When copying an encrypted snapshot, you must have `DescribeKey` permissions on the default CMK. Explicitly denying these permissions results in copy failure. For information about managing CMK keys, see [Authentication and access control for AWS KMS](#).

Archive Amazon EBS snapshots

Amazon EBS Snapshots Archive is a new storage tier that you can use for low-cost, long-term storage of your rarely-accessed snapshots that do not need frequent or fast retrieval.

By default, when you create a snapshot, it is stored in the Amazon EBS Snapshot Standard tier (*standard tier*). Snapshots stored in the standard tier are incremental. This means that only the blocks on the volume that have changed after your most recent snapshot are saved.

When you archive a snapshot, the incremental snapshot is converted to a full snapshot, and it is moved from the standard tier to the Amazon EBS Snapshots Archive tier (*archive tier*). Full snapshots include all of the blocks that were written to the volume at the time when the snapshot was created.

When you need to access an archived snapshot, you can restore it from the archive tier to the standard tier, and then use it in the same way that you use any other snapshot in your account.

Amazon EBS Snapshots Archive offers up to 75 percent lower snapshot storage costs for snapshots that you plan to store for 90 days or longer and that you rarely need to access.

Some typical use cases include:

- Archiving the only snapshot of a volume, such as end-of-project snapshots
- Archiving full, point-in-time incremental snapshots for compliance reasons.
- Archiving monthly, quarterly, or yearly incremental snapshots.

Topics

- [Considerations and limitations \(p. 1786\)](#)
- [Pricing and billing \(p. 1787\)](#)
- [Quotas \(p. 1788\)](#)
- [Guidelines and best practices for archiving snapshots \(p. 1789\)](#)
- [Required IAM permissions \(p. 1798\)](#)
- [Work with snapshot archiving \(p. 1799\)](#)
- [Monitor snapshot archiving \(p. 1806\)](#)

Considerations and limitations

Considerations

- The minimum archive period is 90 days. If you delete or permanently restore an archived snapshot before the minimum archive period of 90 days, you are billed for remaining days in the archive tier, rounded to the nearest hour. For more information, see [Pricing and billing \(p. 1787\)](#).
- It can take up to 72 hours to restore an archived snapshot from the archive tier to the standard tier, depending on the size of the snapshot.
- Archived snapshots are always full snapshots. A full snapshot contains all the blocks written to the volume at the time the snapshot was created. The full snapshot will likely be larger than the incremental snapshot from which it was created. However, if you have only one incremental snapshot of a volume on the standard tier, the size of the full snapshot in the archive tier will be the same size as the snapshot in standard tier. This is because the first snapshot taken of a volume is always a full snapshot.
- Archiving is recommended for monthly, quarterly, or yearly snapshots. Archiving daily incremental snapshots of a single volume can lead to higher costs when compared to keeping them in the standard tier.
- When a snapshot is archived, the data of the snapshot that is referenced by other snapshots in the snapshot lineage are retained in the standard tier. Data and storage costs associated with the referenced data that is retained on the standard tier are allocated to the next snapshot in the lineage. This ensures that subsequent snapshots in the lineage are not affected by the archival.
- If you delete an archived snapshot that matches a Recycle Bin retention rule, the archived snapshot is retained in the Recycle Bin for the retention period defined in the retention rule. To use the snapshot,

you must first recover it from the Recycle Bin and then restore it from the archive tier. For more information, see [Recycle Bin \(p. 2045\)](#) and [Pricing and billing \(p. 1787\)](#).

Limitations

- You can archive snapshots that are in the completed state only.
- You can archive only snapshots that you own in your account. To archive a snapshot that is shared with you, first copy the snapshot to your account and then archive the snapshot copy.
- You can't archive a snapshot of the root device volume of a registered AMI.
- You can't archive snapshots that are associated with an Amazon EBS-backed AMI.
- You can't cancel the snapshot archive or snapshot restore process after it has been started.
- You can't share archived snapshots. If you archive a snapshot that you have shared with other accounts, the accounts with which the snapshot is shared lose access after the snapshot is archived.
- You can't copy an archived snapshot. If you need to copy an archived snapshot, you must first restore it.
- You can't enable fast snapshot restore for an archived snapshot. Fast snapshot restore is automatically disabled when a snapshot is archived. If you need to use fast snapshot restore, you must manually enable it after restoring the snapshot.
- You can't archive snapshots that were created by AWS Backup.

Pricing and billing

Archived snapshots are billed at a rate of \$0.0125 per GB-month. For example, if you archive a 100 GiB snapshot, you are billed \$1.25 (100 GiB * \$0.0125) per month.

Snapshot restores are billed at a rate of \$0.03 per GB of data restored. For example, if you restore a 100 GiB snapshot from the archive tier, you are billed one time for \$3 (100 GiB * \$0.03).

After the snapshot is restored to the standard tier, the snapshot is billed at the standard rate for snapshots of \$0.05 per GB-month.

For more information, see [Amazon EBS pricing](#).

Billing for the minimum archive period

The minimum archive period is 90 days. If you delete or permanently restore an archived snapshot before the minimum archive period of 90 days, you are billed a pro-rated charge equal to the archive tier storage charge for the remaining days, rounded to the nearest hour. For example, if you delete or permanently restore an archived snapshot after 40 days, you are billed for the remaining 50 days of the minimum archive period.

Note

Temporarily restoring an archived snapshot before the minimum archive period of 90 days does not incur this charge.

Temporary restores

When you temporarily restore a snapshot, the snapshot is restored from the archive tier to the standard tier, and a copy of the snapshot remains in the archive tier. You are billed for both the snapshot in the standard tier and the snapshot copy in the archive tier for the duration of the temporary restore period. When the temporarily restored snapshot is removed from the standard tier, you are no longer billed for it, and you are billed for the snapshot in the archive tier only.

Permanent restores

When you permanently restore a snapshot, the snapshot is restored from the archive tier to the standard tier, and the snapshot is deleted from the archive tier. You are billed for the snapshot in the standard tier only.

Deleting snapshots

If you delete a snapshot while it is being archived, you are billed for the snapshot data that has already been moved to the archive tier. This data is subject to the minimum archive period of 90 days and billed accordingly upon deletion. For example, if you archive a 100 GiB snapshot, and you delete the snapshot after only 40 GiB has been archived, you are billed \$1.50 for the minimum archive period of 90 days for the 40 GiB that has already been archived ($\$0.0125 \text{ per GB-month} * 40 \text{ GB} * (90 \text{ days} * 24 \text{ hours}) / (24 \text{ hours/day} * 30\text{-day month})$).

If you delete a snapshot while it is being restored from the archive tier, you are billed for the snapshot restore for the full size of the snapshot (snapshot size * \$0.03). For example, if you restore a 100 GiB snapshot from the archive tier, and you delete the snapshot at any point before the snapshot restore completes, you are billed \$3 (100 GiB snapshot size * \$0.03).

Recycle Bin

Archived snapshots are billed at the rate for archived snapshots while they are in the Recycle Bin. Archived snapshots that are in the Recycle Bin are subject to the minimum archive period of 90 days and they are billed accordingly if they are deleted by Recycle Bin before the minimum archive period. In other words, if a retention rule deletes an archived snapshot from the Recycle Bin before the minimum period of 90 days, you are billed for the remaining days.

If you delete a snapshot that matches a retention rule while the snapshot is being archived, the archived snapshot is retained in the Recycle Bin for the retention period defined in the retention rule. It is billed at the rate for archived snapshots.

If you delete a snapshot that matches a retention rule while the snapshot is being restored, the restored snapshot is retained in the Recycle Bin for the remainder of the retention period, and billed at the standard snapshot rate. To use the restored snapshot, you must first recover it from the Recycle Bin.

For more information, see [Recycle Bin \(p. 2045\)](#).

Cost tracking

Archived snapshots appear in the AWS Cost and Usage Report with their same resource ID and Amazon Resource Name (ARN). For more information, see the [AWS Cost and Usage Report User Guide](#).

You can use the following usage types to identify the associated costs:

- `SnapshotArchiveStorage` — fee for monthly data storage
- `SnapshotArchiveRetrieval` — one-time fee for snapshot restores
- `SnapshotArchiveEarlyDelete` — fee for deleting or permanently restoring a snapshot before the minimum archive period (90 days)

Quotas

This section describes the default quotas for archived and in-progress snapshots.

Quota	Default quota			
Archived snapshots	25			

Quota	Default quota			
per volume				
Concurrent 25 in-progress snapshot archives per account				
Concurrent 5 in-progress snapshot restores per account				

If you need more than the default limits, complete the AWS Support Center [Create case](#) form to request a limit increase.

Guidelines and best practices for archiving snapshots

This section provides some guidelines and best practices for archiving snapshots.

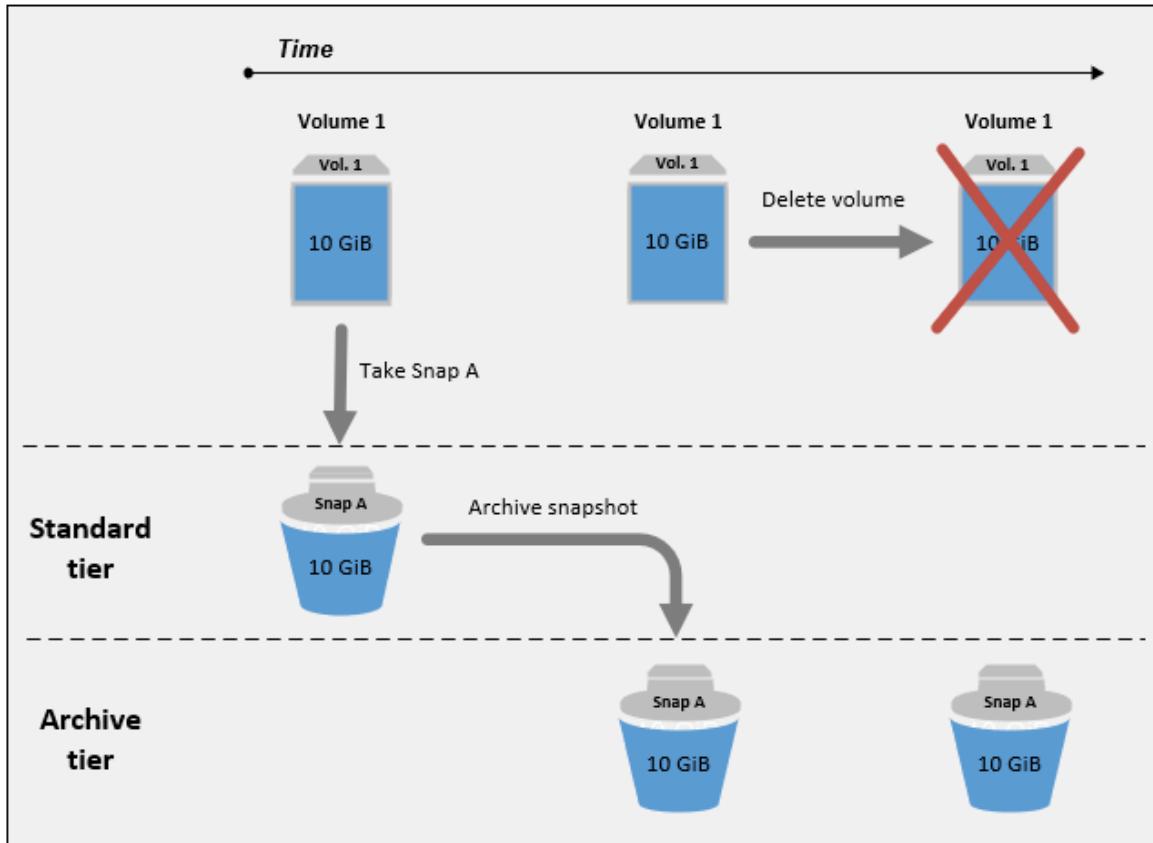

Topics

- [Archiving the only snapshot of a volume \(p. 1789\)](#)
- [Archiving incremental snapshots of a single volume \(p. 1790\)](#)
- [Archiving full snapshots for compliance reasons \(p. 1791\)](#)
- [Determining the reduction in standard tier storage costs \(p. 1792\)](#)

Archiving the only snapshot of a volume

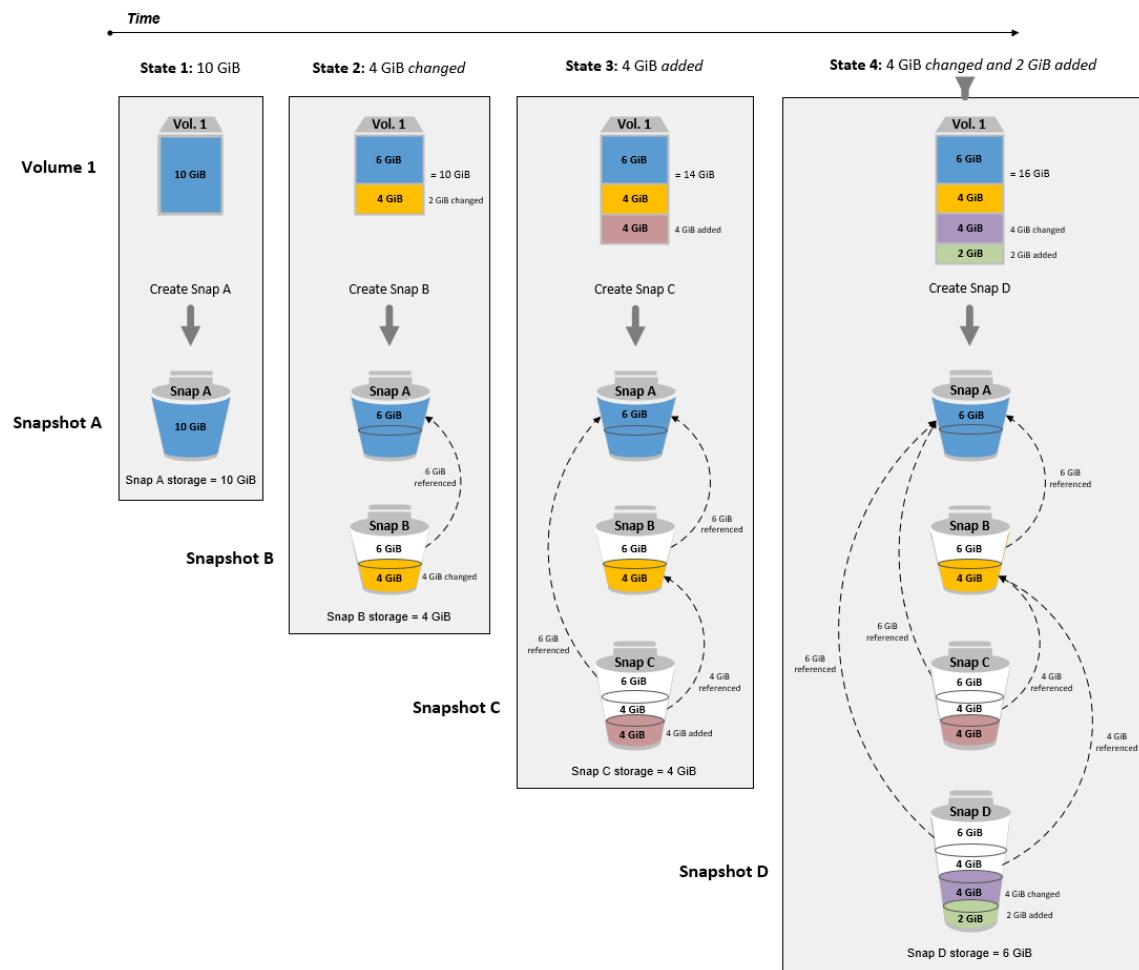

When you have only one snapshot of a volume, the snapshot is always the same size as the blocks written to the volume at the time the snapshot was created. When you archive such a snapshot, the snapshot in the standard tier is converted to an equivalent-sized full snapshot and it is moved from the standard tier to the archive tier.

Archiving these snapshots can help you save with lower storage costs. If you no longer need the source volume, you can delete the volume for further storage cost savings.

Archiving incremental snapshots of a single volume

When you archive an incremental snapshot, the snapshot is converted to a full snapshot and it is moved to the archive tier. For example, in the following image, if you archive **Snap B**, the snapshot is converted to a full snapshot that is 10 GiB in size and moved to the archive tier. Similarly, if you archive **Snap C**, the size of the full snapshot in the archive tier is 14 GiB.

If you are archiving snapshots to reduce your storage costs in the standard tier, you should not archive the first snapshot in a set of incremental snapshots. These snapshots are referenced by subsequent snapshots in the snapshot lineage. In most cases, archiving these snapshots will not reduce storage costs.

Note

You should not archive the last snapshot in a set of incremental snapshots. The last snapshot is the most recent snapshot taken of a volume. You will need this snapshot in the standard tier if you want to create volumes from it in the case of a volume corruption or loss.

If you archive a snapshot that contains data that is referenced by a later snapshot in the lineage, the data storage and storage costs associated with the referenced data are allocated to the later snapshot in the lineage. In this case, archiving the snapshot will not reduce data storage or storage costs. For example, in the preceding image, if you archive **Snap B**, its 4 GiB of data is attributed to **Snap C**. In this case, your overall storage costs will increase because you incur storage costs for the full version of **Snap B** in the archive tier, and your storage costs for the standard tier remain unchanged.

If you archive **Snap C**, your standard tier storage will decrease by 4 GiB because the data is not referenced by any other snapshots later in the lineage. And your archive tier storage will increase by 14 GiB because the snapshot is converted to a full snapshot.

Archiving full snapshots for compliance reasons

You might need to create full backups of volumes on a monthly, quarterly, or yearly basis for compliance reasons. For these backups, you might need standalone snapshots without backward or forward

references to other snapshots in the snapshot lineage. Snapshots archived with EBS Snapshots Archive are full snapshots, and they do not have any references to other snapshots in the lineage. Additionally, you will likely need to retain these snapshots for compliance reasons for several years. EBS Snapshots Archive makes it cost-effective to archive these full snapshots for long-term retention.

Determining the reduction in standard tier storage costs

If you want to archive an incremental snapshot to reduce your storage costs, you should consider the size of the full snapshot in the archive tier and the reduction in storage in the standard tier. This section explains how to do this.

Important

The API responses are data accurate at the point-in-time when the APIs are called. API responses can differ as the data associated with a snapshot changes as a result of changes in the snapshot lineage.

To determine the reduction in storage and storage costs in the standard tier, use the following steps.

1. Check the size of the full snapshot. To determine the full size of the snapshot, use the [list-snapshot-blocks](#) command. For `--snapshot-id`, specify the ID of the snapshot that you want to archive.

```
$ aws ebs list-snapshot-blocks --snapshot-id snapshot_id
```

This returns information about all of the blocks in the specified snapshot. The `BlockIndex` of the last block returned by the command indicates the number of blocks in the snapshot. The number of blocks multiplied by 512 KiB, which is the snapshot block size, gives you a close approximation of the size of the full snapshot in the archive tier ($\text{blocks} * 512 \text{ KiB} = \text{full snapshot size}$).

For example, the following command lists the blocks for snapshot `snap-01234567890abcdef`.

```
$ aws ebs list-snapshot-blocks --snapshot-id snap-01234567890abcdef
```

The following is the command output, with some blocks omitted. The following output indicates that the snapshot includes about 16,383 blocks of data. This approximates to a full snapshot size of about 8 GiB ($16,383 * 512 \text{ KiB} = 7.99 \text{ GiB}$).

```
{
    "VolumeSize": 8,
    "Blocks": [
        {
            "BlockToken": "ABgBAeShfa5RwG+RiWUg2pwmnCU/YMnV7fGMxLbCwfEBEUmnuqac5RmoyVat",
            "BlockIndex": 0
        },
        {
            "BlockToken": "ABgBATdTONyThPUAbQhbUQXsn5TGoY/J17GfE83j9WN7siupav0Tw9E1KpFh",
            "BlockIndex": 1
        },
        {
            "BlockToken": "EBEUmmuqXsn5TGoY/QwmnCU/YMnV74eKE2TSsn5TGoY/E83j9WQhbUQXsn5T",
            "BlockIndex": 4
        },
        .....
        {
            "BlockToken": "yThPUAbQhb5V8xpwmnCU/YMnV74eKE2TSFY1sKP/4r05y47WETdTONyThPUA",
            "BlockIndex": 12890
        },
    ]
}
```

```
{  
    "BlockToken":  
        "ABgBASHKD5V8xEbaRKdxdkZZS4eKE2TSFY1MG1sKP/4r05y47WEHqKaNPcLs",  
        "BlockIndex": 12906  
    },  
    {  
        "BlockToken": "ABgBARROGMUJo6P9X3CFHQGZNQ7av9B6vZtTTqV89Qqc  
+Sk00HWMlwkGXjnA",  
        "BlockIndex": 16383  
    }  
],  
    "VolumeSize": 8,  
    "ExpiryTime": 1637677800.845,  
    "BlockSize": 524288  
}
```

2. Find the source volume from which the snapshot that you want to archive was created. Use the [describe-snapshots](#) command. For --snapshot-id, specify the ID of the snapshot that you want to archive. The VolumeId response parameter indicates the ID of the source volume.

```
$ aws ec2 describe-snapshots --snapshot-id snapshot_id
```

For example, the following command returns information about snapshot snap-09c9114207084f0d9.

```
$ aws ec2 describe-snapshots --snapshot-id snap-09c9114207084f0d9
```

The following is the command output, which indicates that snapshot snap-09c9114207084f0d9 was created from volume vol-0f3e2c292c52b85c3.

```
{  
    "Snapshots": [  
        {  
            "Description": "",  
            "Tags": [],  
            "Encrypted": false,  
            "VolumeId": "vol-0f3e2c292c52b85c3",  
            "State": "completed",  
            "VolumeSize": 8,  
            "StartTime": "2021-11-16T08:29:49.840Z",  
            "Progress": "100%",  
            "OwnerId": "123456789012",  
            "SnapshotId": "snap-09c9114207084f0d9"  
        }  
    ]  
}
```

3. Find all of the snapshots created from the source volume. Use the [describe-snapshots](#) command. Specify the volume-id filter, and for the filter value, specify the volume ID from the previous step.

```
$ aws ec2 describe-snapshots --filters "Name=volume-id, Values=volume_id"
```

For example, the following command returns all snapshots created from volume vol-0f3e2c292c52b85c3.

```
$ aws ec2 describe-snapshots --filters "Name=volume-id, Values=vol-0f3e2c292c52b85c3"
```

The following is the command output, which indicates that three snapshots were created from volume vol-0f3e2c292c52b85c3.

```
{  
    "Snapshots": [  
        {  
            "Description": "",  
            "Tags": [],  
            "Encrypted": false,  
            "VolumeId": "vol-0f3e2c292c52b85c3",  
            "State": "completed",  
            "VolumeSize": 8,  
            "StartTime": "2021-11-14T08:57:39.300Z",  
            "Progress": "100%",  
            "OwnerId": "123456789012",  
            "SnapshotId": "snap-08ca60083f86816b0"  
        },  
        {  
            "Description": "",  
            "Tags": [],  
            "Encrypted": false,  
            "VolumeId": "vol-0f3e2c292c52b85c3",  
            "State": "completed",  
            "VolumeSize": 8,  
            "StartTime": "2021-11-15T08:29:49.840Z",  
            "Progress": "100%",  
            "OwnerId": "123456789012",  
            "SnapshotId": "snap-09c9114207084f0d9"  
        },  
        {  
            "Description": "01",  
            "Tags": [],  
            "Encrypted": false,  
            "VolumeId": "vol-0f3e2c292c52b85c3",  
            "State": "completed",  
            "VolumeSize": 8,  
            "StartTime": "2021-11-16T07:50:08.042Z",  
            "Progress": "100%",  
            "OwnerId": "123456789012",  
            "SnapshotId": "snap-024f49fe8dd853fa8"  
        }  
    ]  
}
```

4. Using the output from the previous command, sort the snapshots by their creation times, from earliest to newest. The StartTime response parameter for each snapshot indicates its creation time, in UTC time format.

For example, the snapshots returned in the previous step arranged by creation time, from earliest to newest, is as follows:

1. snap-08ca60083f86816b0 (earliest – created before the snapshot that you want to archive)
2. snap-09c9114207084f0d9 (the snapshot to archive)
3. snap-024f49fe8dd853fa8 (newest – created after the snapshot that you want to archive)
5. Identify the snapshots that were created immediately before and after the snapshot that you want to archive. In this case, you want to archive snapshot snap-09c9114207084f0d9, which was the second incremental snapshot created in the set of three snapshots. Snapshot snap-08ca60083f86816b0 was created immediately before, and snapshot snap-024f49fe8dd853fa8 was created immediately after.

6. Find the unreferenced data in the snapshot that you want to archive. First, find the blocks that are different between the snapshot that was created immediately before the snapshot that you want to archive, and the snapshot that you want to archive. Use the [list-changed-blocks](#) command. For `--first-snapshot-id`, specify the ID of the snapshot that was created immediately before the snapshot that you want to archive. For `--second-snapshot-id`, specify the ID of the snapshot that you want to archive.

```
$ aws ebs list-changed-blocks --first-snapshot-id snapshot_created_before --second-snapshot-id snapshot_to_archive
```

For example, the following command shows the block indexes for the blocks that are different between snapshot `snap-08ca60083f86816b0` (the snapshot created before the snapshot you want to archive), and snapshot `snap-09c9114207084f0d9` (the snapshot you want to archive).

```
$ aws ebs list-changed-blocks --first-snapshot-id snap-08ca60083f86816b0 --second-snapshot-id snap-09c9114207084f0d9
```

The following shows the command output, with some blocks omitted.

```
{  
    "BlockSize": 524288,  
    "ChangedBlocks": [  
        {  
            "FirstBlockToken": "ABgBAX6y  
+WH6Rm9y5zq1VyeTCmEzGmTT0jNZG1cDirFq1r0VeFbWxsH3W4z/",  
            "SecondBlockToken": "ABgBASyx0bHHBnTERu

            "BlockIndex": 14  
        },  
        {  
            "FirstBlockToken":  
"ABgBAZBfEv4EHs1aSXTxSE3mBZG6CNeIkwxpljzmgSHICG1FmZCyJXzE4r3",  
            "SecondBlockToken":  
"ABgBAVWR7QuQQB0AP2tmNkgS4Aec5KAQVCldnpsc91zBiNmSfW9ouIlbeXWy",  
            "BlockIndex": 15  
        },  
        ....  
        {  
            "SecondBlockToken": "ABgBAeHwXPL+z3DBLjDhwjdAM9+CPGV5V05Q3rEEA  
+ku50P498hjnTAgMhLG",  
        }  
    ]  
}
```

```
        "BlockIndex": 13171
    },
    {
        "SecondBlockToken":
"ABgBAbZcPiVtLx6U3Fb4lAjRdtkJMwW5M2tiCgIp6ZZpcZ8AwXxkjVUUHADq",
        "BlockIndex": 13172
    },
    {
        "SecondBlockToken": "ABgBAVmEd/pQ9VW9hWi0uj0AKcauOnUFCO
+eZ5ASVdWLXWWC04ijfoDTpTVZ",
        "BlockIndex": 13173
    },
    {
        "SecondBlockToken": "ABgBAT/jeN7w
+8ALuNdaiwXmsSfM6t0vMoLBLJ14LKvavw4IiB1d0iykWe6b",
        "BlockIndex": 13174
    },
    {
        "SecondBlockToken": "ABgBAXtGvUhTjjUqkwKXfXzyR2GpQei/
+pJSG/19ESwvt7Hd8GHaUqVs6Zf3",
        "BlockIndex": 13175
    }
],
"ExpiryTime": 1637648751.813,
"VolumeSize": 8
}
```

Next, use the same command to find blocks that are different between the snapshot that you want to archive and the snapshot that was created immediately after it. For `--first-snapshot-id`, specify the ID of the snapshot that you want to archive. For `--second-snapshot-id`, specify the ID of the snapshot that was created immediately after the snapshot that you want to archive.

```
$ aws ebs list-changed-blocks --first-snapshot-id snapshot_to_archive --second-snapshot-id snapshot_created_after
```

For example, the following command shows the block indexes of the blocks that are different between snapshot `snap-09c9114207084f0d9` (the snapshot that you want to archive) and snapshot `snap-024f49fe8dd853fa8` (the snapshot created after the snapshot that you want to archive).

```
$ aws ebs list-changed-blocks --first-snapshot-id snap-09c9114207084f0d9 --second-snapshot-id snap-024f49fe8dd853fa8
```

The following shows the command output, with some blocks omitted.

```
{
    "BlockSize": 524288,
    "ChangedBlocks": [
        {
            "FirstBlockToken": "ABgBAVax0bHHBnTERu

],
"ExpiryTime": 1637692677.286,
"VolumeSize": 8
}

```

7. Compare the output returned by both commands in the previous step. If the same block index appears in both command outputs, it indicates that the block contains unreferenced data.

For example, the command output in the previous step indicates that blocks 4, 5, 13, and 14 are unique to snapshot snap-09c9114207084f0d9 and that they are not referenced by any other snapshots in the snapshot lineage.

To determine the reduction in standard tier storage, multiply the number of blocks that appear in both command outputs by 512 KiB, which is the snapshot block size.

For example, if 9,950 block indexes appear in both command outputs, it indicates that you will decrease standard tier storage by around 4.85 GiB (9,950 blocks * 512 KiB = 4.85 GiB).

8. Determine the storage costs for storing the unreferenced blocks in the standard tier for 90 days. Compare this value with the cost of storing the full snapshot, described in from step 1, in the archive tier. You can determine your costs savings by comparing the values, assuming that you do not restore the full snapshot from the archive tier during the minimum 90-day period. For more information, see [Pricing and billing \(p. 1787\)](#).

Required IAM permissions

By default, users don't have permission to use snapshot archiving. To allow users to use snapshot archiving, you must create IAM policies that grant permission to use specific resources and API actions. For more information, see [Creating IAM policies](#) in the IAM User Guide.

To use snapshot archiving, users need the following permissions.

- `ec2:DescribeSnapshotTierStatus`
- `ec2:ModifySnapshotTier`
- `ec2:RestoreSnapshotTier`

Console users might need additional permissions such as `ec2:DescribeSnapshots`.

To archive and restore encrypted snapshots, the following additional AWS KMS permissions are required.

- `kms>CreateGrant`
- `kmsDecrypt`
- `kmsDescribeKey`

The following is an example IAM policy that gives IAM users permission to archive, restore, and view encrypted and unencrypted snapshots. It includes the `ec2:DescribeSnapshots` permission for console users. If some permissions are not needed, you can remove them from the policy.

Tip

To follow the principle of least privilege, do not allow full access to `kmsCreateGrant`. Instead, use the `kmsGrantIsForAWSResource` condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

```
{  
    "Version": "2012-10-17",  
    "Statement": [{  
        "Effect": "Allow",  
        "Action": [  
            "ec2:DescribeSnapshotTierStatus",  
            "ec2:ModifySnapshotTier",  
            "ec2:RestoreSnapshotTier",  
            "ec2:DescribeSnapshots",  
            "kmsCreateGrant",  
            "kmsDecrypt",  
            "kmsDescribeKey"  
        ],  
        "Resource": "*",  
        "Condition": {  
            "Bool": {  
                "kmsGrantIsForAWSResource": true  
            }  
        }  
    }]  
}
```

```
        }  
    }]  
}
```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center (successor to AWS Single Sign-On):

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the *IAM User Guide*.
- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

Work with snapshot archiving

Topics

- [Archive a snapshot \(p. 1799\)](#)
- [Restore an archived snapshot \(p. 1800\)](#)
- [Modify the restore period or restore type for a temporarily restored snapshot \(p. 1802\)](#)
- [View archived snapshots \(p. 1803\)](#)

Archive a snapshot

You can archive any snapshot that is in the completed state and that you own in your account. You can't archive snapshots that are in the pending or error states, or snapshots that are shared with you. For more information, see [Considerations and limitations \(p. 1786\)](#).

Archived snapshots retain their snapshot ID, encryption status, AWS Identity and Access Management (IAM) permissions, owner information, and resource tags. However, fast snapshot restore and snapshot sharing are automatically disabled after the snapshot is archived.

You can continue to use the snapshot while the archive is in process. As soon as the snapshot tiering status reaches the archival-complete state, you can no longer use the snapshot.

You can archive a snapshot using one of the following methods.

Console

To archive a snapshot

Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

1. In the navigation pane, choose **Snapshots**.
2. In the list of snapshots, select the snapshot to archive and then choose **Actions, Archive snapshot**.
3. To confirm, choose **Archive snapshot**.

AWS CLI

To archive a snapshot

Use the [modify-snapshot-tier](#) AWS CLI command. For `--snapshot-id`, specify the ID of the snapshot to archive. For `--storage-tier`, specify `archive`.

```
$ aws ec2 modify-snapshot-tier \
--snapshot-id snapshot_id \
--storage-tier archive
```

For example, the following command archives snapshot `snap-01234567890abcdef`.

```
$ aws ec2 modify-snapshot-tier \
--snapshot-id snap-01234567890abcdef \
--storage-tier archive
```

The following is the command output. The `TieringStartTime` response parameter indicates the date and time at which the archive process was started, in UTC time format (YYYY-MM-DDTHH:MM:SSZ).

```
{  
    "SnapshotId": "snap-01234567890abcdef",  
    "TieringStartTime": "2021-09-15T16:44:37.574Z"  
}
```

Restore an archived snapshot

Before you can use an archived snapshot, you must first restore it to the standard tier. The restored snapshot has the same snapshot ID, encryption status, IAM permissions, owner information, and resource tags that it had before it was archived. After it is restored, you can use it in the same way that you use any other snapshot in your account. The restored snapshot is always a full snapshot.

When you restore a snapshot, you can choose to restore it **permanently** or **temporarily**.

If you restore a snapshot permanently, the snapshot is moved from the archive tier to the standard tier permanently. The snapshot remains restored and ready for use until you manually re-archive it or you manually delete it. When you permanently restore a snapshot, the snapshot is removed from the archive tier.

If you restore a snapshot temporarily, the snapshot is copied from the archive tier to the standard tier for a restore period that you specify. The snapshot remains restored and ready for use for the restore period only. During the restore period, a copy of the snapshot remains in the archive tier. After the period expires, the snapshot is automatically removed from the standard tier. You can increase or decrease the restore period or change the restore type to permanent at any time during the restore period. For more information, see [Modify the restore period or restore type for a temporarily restored snapshot \(p. 1802\)](#).

You can restore an archived snapshot using one of the following methods.

Console

To restore a snapshot from the archive

Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

1. In the navigation pane, choose **Snapshots**.
2. In the list of snapshots, select the archived snapshot to restore, and then choose **Actions**, **Restore snapshot from archive**.

3. Specify the type of restore to perform. For **Restore type**, do one of the following:
 - To restore the snapshot permanently, select **Permanent**.
 - To restore the snapshot temporarily, select **Temporary**, and then for **Temporary restore period**, enter the number of days for which to restore the snapshot.
4. To confirm, choose **Restore snapshot**.

AWS CLI

To permanently restore an archived snapshot

Use the [restore-snapshot-tier](#) AWS CLI command. For `--snapshot-id`, specify the ID of the snapshot to restore, and include the `--permanent-restore` option.

```
$ aws ec2 restore-snapshot-tier \
--snapshot-id snapshot_id \
--permanent-restore
```

For example, the following command permanently restores snapshot snap-01234567890abcdef.

```
$ aws ec2 restore-snapshot-tier \
--snapshot-id snap-01234567890abcdef \
--permanent-restore
```

The following is the command output.

```
{  
    "SnapshotId": "snap-01234567890abcdef",  
    "IsPermanentRestore": true  
}
```

To temporarily restore an archived snapshot

Use the [restore-snapshot-tier](#) AWS CLI command. Omit the `--permanent-restore` option. For `--snapshot-id`, specify the ID of the snapshot to restore, and for `--temporary-restore-days`, specify the number of days for which to restore the snapshot.

`--temporary-restore-days` must be specified in days. The allowed range is 1 - 180. If you do not specify a value, it defaults to 1 day.

```
$ aws ec2 restore-snapshot-tier \
--snapshot-id snapshot_id \
--temporary-restore-days number_of_days
```

For example, the following command temporarily restores snapshot snap-01234567890abcdef for a restore period of 5 days.

```
$ aws ec2 restore-snapshot-tier \
--snapshot-id snap-01234567890abcdef \
--temporary-restore-days 5
```

The following is the command output.

```
{  
    "SnapshotId": "snap-01234567890abcdef",  
    "RestoreDuration": 5,  
    "IsPermanentRestore": false
```

}

Modify the restore period or restore type for a temporarily restored snapshot

When you restore a snapshot temporarily, you must specify the number of days for which the snapshot is to remain restored in your account. After the restore period expires, the snapshot is automatically removed from the standard tier.

You can change the restore period for a temporarily restored snapshot at any time.

You can choose to either increase or decrease the restore period, or you can change the restore type from temporary to permanent.

If you change the restore period, the new restore period is effective from the current date. For example, if you specify a new restore period of 5 days, the snapshot will remain restored for five days from the current date.

Note

You can end a temporary restore early by setting the restore period to 1 day.

If you change the restore type from temporary to permanent, the snapshot copy is deleted from the archive tier, and the snapshot remains available in your account until you manually re-archive it or delete it.

You can modify the restore period for a snapshot using one of the following methods.

Console

To modify the restore period or restore type

Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

1. In the navigation pane, choose **Snapshots**.
2. In the list of snapshots, select the snapshot that you previously temporarily restored, and then choose **Actions, Restore snapshot from archive**.
3. For **Restore type**, do one of the following:
 - To change the restore type from temporary to permanent, select **Permanent**.
 - To increase or decrease the restore period, keep **Temporary**, and then for **Temporary restore period**, enter the new restore period in days.
4. To confirm, choose **Restore snapshot**.

AWS CLI

To modify the restore period or change the restore type

Use the `restore-snapshot-tier` AWS CLI command. For `--snapshot-id`, specify the ID of the snapshot that you previously temporarily restored. To change the restore type from temporary to permanent, specify `--permanent-restore` and omit `--temporary-restore-days`. To increase or decrease the restore period, omit `--permanent-restore` and for `--temporary-restore-days`, specify the new restore period in days.

Example: Increase or decrease the restore period

The following command changes the restore period for snapshot snap-01234567890abcdef to 10 days.

```
$ aws ec2 restore-snapshot-tier \
```

```
--snapshot-id snap-01234567890abcdef  
--temporary-restore-days 10
```

The following is the command output.

```
{  
    "SnapshotId": "snap-01234567890abcdef",  
    "RestoreDuration": 10,  
    "IsPermanentRestore": false  
}
```

Example: Change restore type to permanent

The following command changes the restore type for snapshot snap-01234567890abcdef from temporary to permanent.

```
$ aws ec2 restore-snapshot-tier \  
--snapshot-id snap-01234567890abcdef  
--permanent-restore
```

The following is the command output.

```
{  
    "SnapshotId": "snap-01234567890abcdef",  
    "IsPermanentRestore": true  
}
```

View archived snapshots

You can view storage tier information for snapshots using one of the following methods.

Console

To view storage tier information for a snapshot

Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

1. In the navigation pane, choose **Snapshots**.
2. In the list of snapshots, select the snapshot and choose the **Storage tier** tab.

The tab provides the following information:

- **Last tier change started on** — The date and time when the last archive or restore was started.
- **Tier change progress** — The progress of the last archive or restore action, as a percentage.
- **Storage tier** — The storage tier for the snapshot. Always archive for archived snapshots, and standard for snapshots stored on the standard tier, including temporarily restored snapshots.
- **Tiering status** — The status of the last archive or restore action.
- **Archive completed on** — The date and time when the archive completed.
- **Temporary restore expires on** — The date and time when a temporarily restored snapshot is set to expire.

AWS CLI

To view archival information about an archived snapshot

Use the [describe-snapshot-tier-status](#) AWS CLI command. Specify the `snapshot-id` filter, and for the filter value, specify the snapshot ID. Alternatively, to view all archived snapshots, omit the filter.

```
$ aws ec2 describe-snapshot-tier-status --filters "Name=snapshot-id,  
Values=snapshot_id"
```

The output includes the following response parameters:

- `Status` — The status of the snapshot. Always completed for archived snapshots. Only snapshots that are in the completed state can be archived.
- `LastTieringStartTime` — The date and time that the archival process started, in UTC time format (YYYY-MM-DDTHH:MM:SSZ).
- `LastTieringOperationState` — The current state of the archival process. Possible states include: archival-in-progress | archival-completed | archival-failed | permanent-restore-in-progress | permanent-restore-completed | permanent-restore-failed | temporary-restore-in-progress | temporary-restore-completed | temporary-restore-failed
- `LastTieringProgress` — The progress of the snapshot archival process, as a percentage.
- `StorageTier` — The storage tier for the snapshot. Always archive for archived snapshots, and standard for snapshots stored on the standard tier, including temporarily restored snapshots.
- `ArchivalCompleteTime` — The date and time that the archival process completed, in UTC time format (YYYY-MM-DDTHH:MM:SSZ).

Example

The following command displays information about snapshot snap-01234567890abcdef.

```
$ aws ec2 describe-snapshot-tier-status --filters "Name=snapshot-id,  
Values=snap-01234567890abcdef"
```

The following is the command output.

```
{  
    "SnapshotTierStatuses": [  
        {  
            "Status": "completed",  
            "ArchivalCompleteTime": "2021-09-15T17:33:16.147Z",  
            "LastTieringProgress": 100,  
            "Tags": [],  
            "VolumeId": "vol-01234567890abcdef",  
            "LastTieringOperationState": "archival-completed",  
            "StorageTier": "archive",  
            "OwnerId": "123456789012",  
            "SnapshotId": "snap-01234567890abcdef",  
            "LastTieringStartTime": "2021-09-15T16:44:37.574Z"  
        }  
    ]  
}
```

To view archived and standard tier snapshots

Use the [describe-snapshot](#) AWS CLI command. For `--snapshot-ids`, specify the ID of the snapshot view.

```
$ aws ec2 describe-snapshots --snapshot-ids snapshot_id
```

For example, the following command displays information about snapshot snap-01234567890abcdef.

```
$ aws ec2 describe-snapshots --snapshot-ids snap-01234567890abcdef
```

The following is the command output. The `StorageTier` response parameter indicates whether the snapshot is currently archived. `archive` indicates that the snapshot is currently archived and stored in the archive tier, and `standard` indicates that the snapshot is currently not archived and that it is stored in the standard tier.

In the following example output, only Snap A is archived. Snap B and Snap C are not archived.

Additionally, the `RestoreExpiryTime` response parameter is returned only for snapshots that are temporarily restored from the archive. It indicates when temporarily restored snapshots are to be automatically removed from the standard tier. It is **not** returned for snapshots that are permanently restored.

In the following example output, Snap C is temporarily restored, and it will be automatically removed from the standard tier at 2021-09-19T21:00:00.000Z (September 19, 2021 at 21:00 UTC).

```
{
    "Snapshots": [
        {
            "Description": "Snap A",
            "Encrypted": false,
            "VolumeId": "vol-01234567890aaaaaaaa",
            "State": "completed",
            "VolumeSize": 8,
            "StartTime": "2021-09-07T21:00:00.000Z",
            "Progress": "100%",
            "OwnerId": "123456789012",
            "SnapshotId": "snap-01234567890aaaaaaaa",
            "StorageTier": "archive",
            "Tags": []
        },
        {
            "Description": "Snap B",
            "Encrypted": false,
            "VolumeId": "vol-09876543210bbbbbb",
            "State": "completed",
            "VolumeSize": 10,
            "StartTime": "2021-09-14T21:00:00.000Z",
            "Progress": "100%",
            "OwnerId": "123456789012",
            "SnapshotId": "snap-09876543210bbbbbb",
            "StorageTier": "standard",
            "RestoreExpiryTime": "2019-09-19T21:00:00.000Z",
            "Tags": []
        },
        {
            "Description": "Snap C",
            "Encrypted": false,
            "VolumeId": "vol-054321543210cccccc",
            "State": "completed",
            "VolumeSize": 12,
            "StartTime": "2021-08-01T21:00:00.000Z",
            "Progress": "100%",
            "OwnerId": "123456789012",
            "SnapshotId": "snap-054321543210cccccc",
            "StorageTier": "standard",
            "Tags": []
        }
    ]
}
```

}

To view only snapshots that are stored in the archive tier or the standard tier

Use the [describe-snapshot](#) AWS CLI command. Include the --filter option, for the filter name, specify storage-tier, and for the filter value specify either archive or standard.

```
$ aws ec2 describe-snapshots --filters "Name=storage-tier,Values=archive/standard"
```

For example, the following command displays only archived snapshots.

```
$ aws ec2 describe-snapshots --filters "Name=storage-tier,Values=archive"
```

Monitor snapshot archiving

Amazon EBS emits events related to snapshot archiving actions. You can use AWS Lambda and Amazon CloudWatch Events to handle event notifications programmatically. Events are emitted on a best effort basis. For more information, see the [Amazon CloudWatch Events User Guide](#).

The following events are available:

- archiveSnapshot — Emitted when a snapshot archive action succeeds or fails.

The following is an example of an event that is emitted when a snapshot archive action succeeds.

```
{  
    "version": "0",  
    "id": "01234567-0123-0123-0123-012345678901",  
    "detail-type": "EBS Snapshot Notification",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "2021-05-25T13:12:22Z",  
    "region": "us-east-1",  
    "resources": [  
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"  
    ],  
    "detail": {  
        "event": "archiveSnapshot",  
        "result": "succeeded",  
        "cause": "",  
        "request-id": "123456789",  
        "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",  
        "start_time": "2021-05-25T13:12:22Z",  
        "end_time": "2021-05-45T15:30:00Z",  
        "recycle_bin_exit_time": "2021-10-45T15:30:00Z"  
    }  
}
```

The following is an example of an event that is emitted when a snapshot archive action fails.

```
{  
    "version": "0",  
    "id": "01234567-0123-0123-0123-012345678901",  
    "detail-type": "EBS Snapshot Notification",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "2021-05-25T13:12:22Z",  
    "region": "us-east-1",  
    "resources": [  
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
```

```
],
  "detail": {
    "event": "archiveSnapshot",
    "result": "failed",
    "cause": "Source snapshot ID is not valid",
    "request-id": "1234567890",
    "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
    "startTime": "2021-05-25T13:12:22Z",
    "endTime": "2021-05-45T15:30:00Z",
    "recycleBinExitTime": "2021-10-45T15:30:00Z"
  }
}
```

- `permanentRestoreSnapshot` — Emitted when a permanent restore action succeeds or fails.

The following is an example of an event that is emitted when a permanent restore action succeeds.

```
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Snapshot Notification",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "2021-05-25T13:12:22Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
  ],
  "detail": {
    "event": "permanentRestoreSnapshot",
    "result": "succeeded",
    "cause": "",
    "request-id": "1234567890",
    "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
    "startTime": "2021-05-25T13:12:22Z",
    "endTime": "2021-10-45T15:30:00Z"
  }
}
```

The following is an example of an event that is emitted when a permanent restore action fails.

```
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Snapshot Notification",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "2021-05-25T13:12:22Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
  ],
  "detail": {
    "event": "permanentRestoreSnapshot",
    "result": "failed",
    "cause": "Source snapshot ID is not valid",
    "request-id": "1234567890",
    "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
    "startTime": "2021-05-25T13:12:22Z",
    "endTime": "2021-05-45T15:30:00Z",
    "recycleBinExitTime": "2021-10-45T15:30:00Z"
  }
}
```

- **temporaryRestoreSnapshot** — Emitted when a temporary restore action succeeds or fails.

The following is an example of an event that is emitted when a temporary restore action succeeds.

```
{  
    "version": "0",  
    "id": "01234567-0123-0123-0123-012345678901",  
    "detail-type": "EBS Snapshot Notification",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "2021-05-25T13:12:22Z",  
    "region": "us-east-1",  
    "resources": [  
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"  
    ],  
    "detail": {  
        "event": "temporaryRestoreSnapshot",  
        "result": "succeeded",  
        "cause": "",  
        "request-id": "1234567890",  
        "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",  
        "startTime": "2021-05-25T13:12:22Z",  
        "endTime": "2021-05-45T15:30:00Z",  
        "restoreExpiryTime": "2021-06-45T15:30:00Z",  
        "recycleBinExitTime": "2021-10-45T15:30:00Z"  
    }  
}
```

The following is an example of an event that is emitted when a temporary restore action fails.

```
{  
    "version": "0",  
    "id": "01234567-0123-0123-0123-012345678901",  
    "detail-type": "EBS Snapshot Notification",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "2021-05-25T13:12:22Z",  
    "region": "us-east-1",  
    "resources": [  
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"  
    ],  
    "detail": {  
        "event": "temporaryRestoreSnapshot",  
        "result": "failed",  
        "cause": "Source snapshot ID is not valid",  
        "request-id": "1234567890",  
        "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",  
        "startTime": "2021-05-25T13:12:22Z",  
        "endTime": "2021-05-45T15:30:00Z",  
        "recycleBinExitTime": "2021-10-45T15:30:00Z"  
    }  
}
```

- **restoreExpiry** — Emitted when the restore period for a temporarily restored snapshot expires.

The following is an example.

```
{  
    "version": "0",  
    "id": "01234567-0123-0123-0123-012345678901",  
    "detail-type": "EBS Snapshot Notification",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "2021-05-25T13:12:22Z",  
    "region": "us-east-1",  
    "resources": [  
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"  
    ]  
}
```

```
"time": "2021-05-25T13:12:22Z",
"region": "us-east-1",
"resources": [
    "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
],
"detail": {
    "event": "restoryExpiry",
    "result": "succeeded",
    "cause": "",
    "request-id": "1234567890",
    "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
    "startTime": "2021-05-25T13:12:22Z",
    "endTime": "2021-05-45T15:30:00Z",
    "recycleBinExitTime": "2021-10-45T15:30:00Z"
}
```

View Amazon EBS snapshot information

You can view detailed information about your snapshots using one of the following methods.

Console

To view snapshot information using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Snapshots**.
3. To view only your snapshots that you own, in the top-left corner of the screen, choose **Owned by me**. You can also filter the list of snapshots using tags and other snapshot attributes. In the **Filter** field, select the attribute field, and then select or enter the attribute value. For example, to view only encrypted snapshots, select **Encryption**, and then enter **true**.
4. To view more information about a specific snapshot, choose its ID in the list.

AWS CLI

To view snapshot information using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [describe-snapshots](#) (AWS CLI)
- [Get-EC2Snapshot](#) (AWS Tools for Windows PowerShell)

Example Example 1: Filter based on tags

The following command describes the snapshots with the tag Stack=production.

```
aws ec2 describe-snapshots --filters Name>tag:Stack,Values=production
```

Example Example 2: Filter based on volume

The following command describes the snapshots created from the specified volume.

```
aws ec2 describe-snapshots --filters Name=volume-id,Values=vol-049df61146c4d7901
```

Example Example 3: Filter based on snapshot age

With the AWS CLI, you can use JMESPath to filter results using expressions. For example, the following command displays the IDs of all snapshots created by your AWS account (represented by [123456789012](#)) before the specified date (represented by [2020-03-31](#)). If you do not specify the owner, the results include all public snapshots.

```
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[?(StartTime<='2020-03-31')].[SnapshotId]" --output text
```

The following command displays the IDs of all snapshots created in the specified date range.

```
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[?(StartTime>='2019-01-01') && (StartTime<='2019-12-31')].[SnapshotId]" --output text
```

Share an Amazon EBS snapshot

You can modify the permissions of a snapshot if you want to share it with other AWS accounts. You can share snapshots publicly with all other AWS accounts, or you can share them privately with individual AWS accounts that you specify. Users that you have authorized can use the snapshots that you share to create their own EBS volumes, while your original snapshot remains unaffected.

Important

When you share a snapshot, you are giving others access to all of the data on the snapshot. Share snapshots only with people that you trust with *all* of your snapshot data.

Topics

- [Before you share a snapshot \(p. 1810\)](#)
- [Share a snapshot \(p. 1810\)](#)
- [Share a KMS key \(p. 1812\)](#)
- [View snapshots that are shared with you \(p. 1813\)](#)
- [Use snapshots that are shared with you \(p. 1814\)](#)
- [Determine the use of snapshots that you share \(p. 1814\)](#)

Before you share a snapshot

The following considerations apply to sharing snapshots:

- Snapshots are constrained to the Region in which they were created. To share a snapshot with another Region, copy the snapshot to that Region and then share the copy. For more information, see [Copy an Amazon EBS snapshot \(p. 1781\)](#).
- You can't share snapshots that are encrypted with the default AWS managed key. You can only share snapshots that are encrypted with a customer managed key. For more information, see [Creating Keys](#) in the *AWS Key Management Service Developer Guide*.
- You can share only unencrypted snapshots publicly.
- When you share an encrypted snapshot, you must also share the customer managed key used to encrypt the snapshot. For more information, see [Share a KMS key \(p. 1812\)](#).

Share a snapshot

You can share a snapshot using one of the methods described in the section.

Console

To share a snapshot

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the snapshot to share, and then choose **Actions, Modify permissions**.
4. Specify the snapshot's permissions. *Current setting* indicates the snapshot's current sharing permissions.
 - To share the snapshot publicly with all AWS accounts, choose **Public**.
 - To share the snapshot privately with specific AWS accounts, choose **Private**. Then, in the **Sharing accounts** section, choose **Add account**, and enter the 12-digit account ID (without hyphens) of the account to share with.
5. Choose **Save changes**.

AWS CLI

The permissions for a snapshot are specified using the `createVolumePermission` attribute of the snapshot. To make a snapshot public, set the group to `all`. To share a snapshot with a specific AWS account, set the user to the ID of the AWS account.

To share a snapshot publicly

Use one of the following commands.

- [modify-snapshot-attribute](#) (AWS CLI)

For `--attribute`, specify `createVolumePermission`. For `--operation-type`, specify `add`.
For `--group-names`, specify `all`.

```
$ aws ec2 modify-snapshot-attribute --snapshot-id 1234567890abcdef0 --attribute createVolumePermission --operation-type add --group-names all
```

- [Edit-EC2SnapshotAttribute](#) (AWS Tools for Windows PowerShell)

For `-Attribute`, specify `CreateVolumePermission`. For `-OperationType`, specify `Add`. For `-GroupName`, specify `all`.

```
PS C:\> Edit-EC2SnapshotAttribute -SnapshotId 1234567890abcdef0 -Attribute CreateVolumePermission -OperationType Add -GroupName all
```

To share a snapshot privately

Use one of the following commands.

- [modify-snapshot-attribute](#) (AWS CLI)

For `--attribute`, specify `createVolumePermission`. For `--operation-type`, specify `add`.
For `--user-ids`, specify the 12-digit IDs of the AWS accounts with which to share the snapshots.

```
$ aws ec2 modify-snapshot-attribute --snapshot-id 1234567890abcdef0 --attribute createVolumePermission --operation-type add --user-ids 123456789012
```

- [Edit-EC2SnapshotAttribute](#) (AWS Tools for Windows PowerShell)

For **-Attribute**, specify `CreateVolumePermission`. For **-OperationType**, specify `Add`. For **UserId**, specify the 12-digit IDs of the AWS accounts with which to share the snapshots.

```
PS C:\> Edit-EC2SnapshotAttribute -SnapshotId 1234567890abcdef0 -Attribute CreateVolumePermission -OperationType Add -UserId 123456789012
```

Share a KMS key

When you share an encrypted snapshot, you must also share the customer managed key used to encrypt the snapshot. You can apply cross-account permissions to a customer managed key either when it is created or at a later time.

Users of your shared customer managed key who are accessing encrypted snapshots must be granted permissions to perform the following actions on the key:

- `kms:DescribeKey`
- `kms:CreateGrant`
- `kms:GenerateDataKey`
- `kms:ReEncrypt`
- `kms:Decrypt`

Tip

To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the `kms:GrantIsForAWSResource` condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service.

For more information about controlling access to a customer managed key, see [Using key policies in AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

To share customer managed key using the AWS KMS console

1. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. Choose **Customer managed keys** in the navigation pane.
4. In the **Alias** column, choose the alias (text link) of the customer managed key that you used to encrypt the snapshot. The key details open in a new page.
5. In the **Key policy** section, you see either the *policy view* or the *default view*. The policy view displays the key policy document. The default view displays sections for **Key administrators**, **Key deletion**, **Key Use**, and **Other AWS accounts**. The default view displays if you created the policy in the console and have not customized it. If the default view is not available, you'll need to manually edit the policy in the policy view. For more information, see [Viewing a Key Policy \(Console\)](#) in the *AWS Key Management Service Developer Guide*.

Use either the policy view or the default view, depending on which view you can access, to add one or more AWS account IDs to the policy, as follows:

- (Policy view) Choose **Edit**. Add one or more AWS account IDs to the following statements: "Allow use of the key" and "Allow attachment of persistent resources". Choose **Save changes**. In the following example, the AWS account ID 444455556666 is added to the policy.

```
{
```

```
"Sid": "Allow use of the key",
"Effect": "Allow",
"Principal": {"AWS": [
    "arn:aws:iam::111122223333:user/KeyUser",
    "arn:aws:iam::444455556666:root"
]},
>Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:DescribeKey"
],
"Resource": "*"
},
{
"Sid": "Allow attachment of persistent resources",
"Effect": "Allow",
"Principal": {"AWS": [
    "arn:aws:iam::111122223333:user/KeyUser",
    "arn:aws:iam::444455556666:root"
]},
>Action": [
    "kms>CreateGrant",
    "kms>ListGrants",
    "kms:RevokeGrant"
],
"Resource": "*",
"Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
}
```

- (Default view) Scroll down to **Other AWS accounts**. Choose **Add other AWS accounts** and enter the AWS account ID as prompted. To add another account, choose **Add another AWS account** and enter the AWS account ID. When you have added all AWS accounts, choose **Save changes**.

View snapshots that are shared with you

You can view snapshots that are shared with you using one of the following methods.

Console

To view shared snapshots using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Snapshots**.
3. Filter the listed snapshots. In the top-left corner of the screen, choose one of the following options:
 - **Private snapshots** — To view only snapshots that are shared with you privately.
 - **Public snapshots** — To view only snapshots that are shared with you publicly.

AWS CLI

To view snapshot permissions using the command line

Use one of the following commands:

- [describe-snapshot-attribute](#) (AWS CLI)
- [Get-EC2SnapshotAttribute](#) (AWS Tools for Windows PowerShell)

Use snapshots that are shared with you

To use a shared unencrypted snapshot

Locate the shared snapshot by ID or description. For more information, see [View snapshots that are shared with you \(p. 1813\)](#). You can use this snapshot as you would any other snapshot that you own in your account. For example, you can create a volume from the snapshot or copy it to a different Region.

To use a shared encrypted snapshot

Locate the shared snapshot by ID or description. For more information, see [View snapshots that are shared with you \(p. 1813\)](#). Create a copy of the shared snapshot in your account, and encrypt the copy with a KMS key that you own. You can then use the copy to create volumes or you can copy it to different Regions.

Determine the use of snapshots that you share

You can use AWS CloudTrail to monitor whether a snapshot that you have shared with others is copied or used to create a volume. The following events are logged in CloudTrail:

- **SharedSnapshotCopyInitiated** — A shared snapshot is being copied.
- **SharedSnapshotVolumeCreated** — A shared snapshot is being used to create a volume.

For more information about using CloudTrail, see [Log Amazon EC2 and Amazon EBS API calls with AWS CloudTrail \(p. 1216\)](#).

Recover snapshots from the Recycle Bin

Recycle Bin is a data recovery feature that enables you to restore accidentally deleted Amazon EBS snapshots and EBS-backed AMIs. When using Recycle Bin, if your resources are deleted, they are retained in the Recycle Bin for a time period that you specify before being permanently deleted.

You can restore a resource from the Recycle Bin at any time before its retention period expires. After you restore a resource from the Recycle Bin, the resource is removed from the Recycle Bin and you can use it in the same way that you use any other resource of that type in your account. If the retention period expires and the resource is not restored, the resource is permanently deleted from the Recycle Bin and it is no longer available for recovery.

Snapshots in the Recycle Bin are billed at the same rate as regular snapshots in your account. There are no additional charges for using Recycle Bin and retention rules. For more information, see [Amazon EBS pricing](#).

For more information, see [Recycle Bin \(p. 2045\)](#).

Topics

- [Permissions for working with snapshots in the Recycle Bin \(p. 1814\)](#)
- [View snapshots in the Recycle Bin \(p. 1816\)](#)
- [Restore snapshots from the Recycle Bin \(p. 1816\)](#)

Permissions for working with snapshots in the Recycle Bin

By default, users don't have permission to work with snapshots that are in the Recycle Bin. To allow users to work with these resources, you must create IAM policies that grant permission to use specific resources and API actions. Once the policies are created, you must add permissions to your users, groups, or roles.

To view and recover snapshots that are in the Recycle Bin, users must have the following permissions:

- `ec2>ListSnapshotsInRecycleBin`
- `ec2>RestoreSnapshotFromRecycleBin`

To manage tags for snapshots in the Recycle Bin, users need the following additional permissions.

- `ec2>CreateTags`
- `ec2>DeleteTags`

To use the Recycle Bin console, users need the `ec2>DescribeTags` permission.

The following is an example IAM policy. It includes the `ec2>DescribeTags` permission for console users, and it includes the `ec2>CreateTags` and `ec2>DeleteTags` permissions for managing tags. If the permissions are not needed, you can remove them from the policy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ec2>ListSnapshotsInRecycleBin",  
                "ec2>RestoreSnapshotFromRecycleBin"  
            ],  
            "Resource": "*"  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ec2>CreateTags",  
                "ec2>DeleteTags",  
                "ec2>DescribeTags"  
            ],  
            "Resource": "arn:aws:ec2:Region:account-id:snapshot/*"  
        },  
    ]  
}
```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center (successor to AWS Single Sign-On):

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the *IAM User Guide*.
- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

For more information about the permissions needed to use Recycle Bin, see [Permissions for working with Recycle Bin and retention rules \(p. 2049\)](#).

View snapshots in the Recycle Bin

While a snapshot is in the Recycle Bin, you can view limited information about it, including:

- The ID of the snapshot.
- The snapshot description.
- The ID of the volume from which the snapshot was created.
- The date and time when the snapshot was deleted and it entered Recycle Bin.
- The date and time when the retention period expires. The snapshot will be permanently deleted from the Recycle Bin at this time.

You can view the snapshots in the Recycle Bin using one of the following methods.

Recycle Bin console

To view snapshots in the Recycle Bin using the console

1. Open the Recycle Bin console at <https://console.aws.amazon.com/rbin/home/>
2. In the navigation pane, choose **Recycle Bin**.
3. The grid lists all of the snapshots that are currently in the Recycle Bin. To view the details for a specific snapshot, select it in the grid and choose **Actions, View details**.

AWS CLI

To view snapshots in the Recycle Bin using the AWS CLI

Use the [list-snapshots-in-recycle-bin](#) AWS CLI command. Include the `--snapshot-id` option to view a specific snapshot. Or omit the `--snapshot-id` option to view all snapshots in the Recycle Bin.

```
C:\> aws ec2 list-snapshots-in-recycle-bin --snapshot-id snapshot_id
```

For example, the following command provides information about snapshot `snap-01234567890abcdef` in the Recycle Bin.

```
C:\> aws ec2 list-snapshots-in-recycle-bin --snapshot-id snap-01234567890abcdef
```

Example output:

```
{  
    "SnapshotRecycleBinInfo": [  
        {  
            "Description": "Monthly data backup snapshot",  
            "RecycleBinEnterTime": "2021-12-01T13:00:00.000Z",  
            "RecycleBinExitTime": "2021-12-15T13:00:00.000Z",  
            "VolumeId": "vol-abcdef09876543210",  
            "SnapshotId": "snap-01234567890abcdef"  
        }  
    ]  
}
```

Restore snapshots from the Recycle Bin

You can't use a snapshot in any way while it is in the Recycle Bin. To use the snapshot, you must first restore it. When you restore a snapshot from the Recycle Bin, the snapshot is immediately available for

use, and it is removed from the Recycle Bin. You can use a restored snapshot in the same way that you use any other snapshot in your account.

You can restore a snapshot from the Recycle Bin using one of the following methods.

Recycle Bin console

To restore a snapshot from the Recycle Bin using the console

1. Open the Recycle Bin console at <https://console.aws.amazon.com/rbin/home/>
2. In the navigation pane, choose **Recycle Bin**.
3. The grid lists all of the snapshots that are currently in the Recycle Bin. Select the snapshot to restore and choose **Recover**.
4. When prompted, choose **Recover**.

AWS CLI

To restore a deleted snapshot from the Recycle Bin using the AWS CLI

Use the [restore-snapshot-from-recycle-bin](#) AWS CLI command. For `--snapshot-id`, specify the ID of the snapshot to restore.

```
C:\> aws ec2 restore-snapshot-from-recycle-bin --snapshot-id snapshot_id
```

For example, the following command restores snapshot snap-01234567890abcdef from the Recycle Bin.

```
C:\> aws ec2 restore-snapshot-from-recycle-bin --snapshot-id snap-01234567890abcdef
```

Example output:

```
{  
    "SnapshotId": "snap-01234567890abcdef",  
    "Description": "Monthly data backup snapshot",  
    "Encrypted": false,  
    "OwnerId": "111122223333",  
    "Progress": "100%",  
    "StartTime": "2021-12-01T13:00:00.000000+00:00",  
    "State": "recovering",  
    "VolumeId": "vol-ffffffff",  
    "VolumeSize": 30  
}
```

Amazon EBS local snapshots on Outposts

Amazon EBS snapshots are a point-in-time copy of your EBS volumes.

By default, snapshots of EBS volumes on an Outpost are stored in Amazon S3 in the Region of the Outpost. You can also use Amazon EBS local snapshots on Outposts to store snapshots of volumes on an Outpost locally in Amazon S3 on the Outpost itself. This ensures that the snapshot data resides on the Outpost, and on your premises. In addition, you can use AWS Identity and Access Management (IAM) policies and permissions to set up data residency enforcement policies to ensure that snapshot data does not leave the Outpost. This is especially useful if you reside in a country or region that is not yet served by an AWS Region and that has data residency requirements.

This topic provides information about working with Amazon EBS local snapshots on Outposts. For more information about Amazon EBS snapshots and about working with snapshots in an AWS Region, see [Amazon EBS snapshots \(p. 1757\)](#).

For more information about AWS Outposts, see [AWS Outposts Features](#) and the [AWS Outposts User Guide](#). For pricing information, see [AWS Outposts pricing](#).

Topics

- [Frequently asked questions \(p. 1818\)](#)
- [Prerequisites \(p. 955\)](#)
- [Considerations \(p. 343\)](#)
- [Controlling access with IAM \(p. 1820\)](#)
- [Working with local snapshots \(p. 1821\)](#)

Frequently asked questions

1. What are local snapshots?

By default, Amazon EBS snapshots of volumes on an Outpost are stored in Amazon S3 in the Region of the Outpost. If the Outpost is provisioned with Amazon S3 on Outposts, you can choose to store the snapshots locally on the Outpost itself. Local snapshots are incremental, which means that only the blocks of the volume that have changed after your most recent snapshot are saved. You can use these snapshots to restore a volume on the same Outpost as the snapshot at any time. For more information about Amazon EBS snapshots, see [Amazon EBS snapshots \(p. 1757\)](#).

2. Why should I use local snapshots?

Snapshots are a convenient way of backing up your data. With local snapshots, all of your snapshot data is stored locally on the Outpost. This means that it does not leave your premises. This is especially useful if you reside in a country or region that is not yet served by an AWS Region and that has residency requirements.

Additionally, using local snapshots can help to reduce the bandwidth used for communication between the Region and the Outpost in bandwidth constrained environments.

3. How do I enforce snapshot data residency on Outposts?

You can use AWS Identity and Access Management (IAM) policies to control the permissions that principals (AWS accounts, IAM users, and IAM roles) have when working with local snapshots and to enforce data residency. You can create a policy that prevents principals from creating snapshots from Outpost volumes and instances and storing the snapshots in an AWS Region. Currently, copying snapshots and images from an Outpost to a Region is not supported. For more information, see [Controlling access with IAM \(p. 1820\)](#).

4. Are multi-volume, crash-consistent local snapshots supported?

Yes, you can create multi-volume, crash-consistent local snapshots from instances on an Outpost.

5. How do I create local snapshots?

You can create snapshots manually using the AWS Command Line Interface (AWS CLI) or the Amazon EC2 console. For more information see, [Working with local snapshots \(p. 1821\)](#). You can also automate the lifecycle of local snapshots using Amazon Data Lifecycle Manager. For more information see, [Automate snapshots on an Outpost \(p. 1826\)](#).

6. Can I create, use, or delete local snapshots if my Outpost loses connectivity to its Region?

No. The Outpost must have connectivity with its Region as the Region provides the access, authorization, logging, and monitoring services that are critical for your snapshots' health. If there is no connectivity, you can't create new local snapshots, create volumes or launch instances from existing local snapshots, or delete local snapshots.

7. How quickly is Amazon S3 storage capacity made available after deleting local snapshots?

Amazon S3 storage capacity becomes available within 72 hours after deleting local snapshots and the volumes that reference them.

8. How can I ensure that I do not run out of Amazon S3 capacity on my Outpost?

We recommend that you use Amazon CloudWatch alarms to monitor your Amazon S3 storage capacity, and delete snapshots and volumes that you no longer need to avoid running out of storage capacity. If you are using Amazon Data Lifecycle Manager to automate the lifecycle of local snapshots, ensure that your snapshot retention policies do not retain snapshots for longer than is needed.

9. What happens if I run out of local Amazon S3 capacity on my Outposts?

If you run out of local Amazon S3 capacity on your Outposts, Amazon Data Lifecycle Manager will not be able to successfully create local snapshots on the Outposts. Amazon Data Lifecycle Manager will attempt to create the local snapshots on the Outposts, but the snapshots immediately transition to the error state and they are eventually deleted by Amazon Data Lifecycle Manager. We recommend that you use the `SnapshotsCreateFailed` Amazon CloudWatch metric to monitor your snapshot lifecycle policies for snapshot creation failures. For more information, see [Monitor your policies using Amazon CloudWatch \(p. 1902\)](#).

10. Can I use local snapshots and AMIs backed by local snapshots with Spot Instances and Spot Fleet?

No, you can't use local snapshots or AMIs backed by local snapshots to launch Spot Instances or a Spot Fleet.

11. Can I use local snapshots and AMIs backed by local snapshots with Amazon EC2 Auto Scaling?

Yes, you can use local snapshots and AMIs backed by local snapshots to launch Auto Scaling groups in a subnet that is on the same Outpost as the snapshots. The Amazon EC2 Auto Scaling group service-linked role must have permission to use the KMS key used to encrypt the snapshots.

You can't use local snapshots or AMIs backed by local snapshots to launch Auto Scaling groups in an AWS Region.

Prerequisites

To store snapshots on an Outpost, you must have an Outpost that is provisioned with Amazon S3 on Outposts. For more information about Amazon S3 on Outposts, see [Using Amazon S3 on Outposts](#) in the *Amazon Simple Storage Service User Guide*.

Considerations

Keep the following in mind when working with local snapshots.

- Outposts must have connectivity to their AWS Region to use local snapshots.
- Snapshot metadata is stored in the AWS Region associated with the Outpost. This does not include any snapshot data.
- Snapshots stored on Outposts are encrypted by default. Unencrypted snapshots are not supported. Snapshots that are created on an Outpost and snapshots that are copied to an Outpost are encrypted using the default KMS key for the Region or a different KMS key that you specify at the time of the request.
- When you create a volume on an Outpost from a local snapshot, you cannot re-encrypt the volume using a different KMS key. Volumes created from local snapshots must be encrypted using the same KMS key as the source snapshot.
- After you delete local snapshots from an Outpost, the Amazon S3 storage capacity used by the deleted snapshots becomes available within 72 hours. For more information, see [Delete local snapshots \(p. 1826\)](#).
- You can't export local snapshots from an Outpost.

- You can't enable fast snapshot restore for local snapshots.
- EBS direct APIs are not supported with local snapshots.
- You can't copy local snapshots or AMIs from an Outpost to an AWS Region, from one Outpost to another, or within an Outpost. However, you can copy snapshots from an AWS Region to an Outpost. For more information, see [Copy snapshots from an AWS Region to an Outpost \(p. 1824\)](#).
- When copying a snapshot from an AWS region to an Outpost, the data is transferred over the service link. Copying multiple snapshots simultaneously could impact other services running on the Outpost.
- You can't share local snapshots.
- You must use IAM policies to ensure that your data residency requirements are met. For more information, see [Controlling access with IAM \(p. 1820\)](#).
- Local snapshots are incremental backups. Only the blocks in the volume that have changed after your most recent snapshot are saved. Each local snapshot contains all of the information that is needed to restore your data (from the moment when the snapshot was taken) to a new EBS volume. For more information, see [How snapshots work \(p. 1758\)](#).
- You can't use IAM policies to enforce data residency for **CopySnapshot** and **CopyImage** actions.

Controlling access with IAM

You can use AWS Identity and Access Management (IAM) policies to control the permissions that principals (AWS accounts, IAM users, and IAM roles) have when working with local snapshots. The following are example policies that you can use to grant or deny permission to perform specific actions with local snapshots.

Important

Copying snapshots and images from an Outpost to a Region is currently not supported. As a result, you currently can't use IAM policies to enforce data residency for **CopySnapshot** and **CopyImage** actions.

Topics

- [Enforce data residency for snapshots \(p. 1820\)](#)
- [Prevent principals from deleting local snapshots \(p. 1821\)](#)

Enforce data residency for snapshots

The following example policy prevents all principals from creating snapshots from volumes and instances on Outpost `arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef` and storing the snapshot data in an AWS Region. Principals can still create local snapshots. This policy ensures that all snapshots remain on the Outpost.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Deny",  
            "Action": [  
                "ec2:CreateSnapshot",  
                "ec2:CreateSnapshots"  
            ],  
            "Resource": "arn:aws:ec2:us-east-1::snapshot/*",  
            "Condition": {  
                "StringEquals": {  
                    "ec2:SourceOutpostArn": "arn:aws:outposts:us-  
east-1:123456789012:outpost/op-1234567890abcdef0"  
                },  
                "Null": {  
                    "ec2:OutpostArn": "true"  
                }  
            }  
        }  
    ]  
}
```

```
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateSnapshot",
                "ec2:CreateSnapshots"
            ],
            "Resource": "*"
        }
    ]
}
```

Prevent principals from deleting local snapshots

The following example policy prevents all principals from deleting local snapshots that are stored on Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "ec2:DeleteSnapshot"
            ],
            "Resource": "arn:aws:ec2:us-east-1::snapshot/*",
            "Condition": {
                "StringEquals": {
                    "ec2:OutpostArn": "arn:aws:outposts:us-east-1:123456789012:outpost/
op-1234567890abcdef0"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DeleteSnapshot"
            ],
            "Resource": "*"
        }
    ]
}
```

Working with local snapshots

The following sections explain how to use local snapshots.

Topics

- [Rules for storing snapshots \(p. 1822\)](#)
- [Create local snapshots from volumes on an Outpost \(p. 1822\)](#)
- [Create multi-volume local snapshots from instances on an Outpost \(p. 1823\)](#)
- [Create AMIs from local snapshots \(p. 1824\)](#)
- [Copy snapshots from an AWS Region to an Outpost \(p. 1824\)](#)
- [Copy AMIs from an AWS Region to an Outpost \(p. 1825\)](#)
- [Create volumes from local snapshots \(p. 1826\)](#)
- [Launch instances from AMIs backed by local snapshots \(p. 1826\)](#)
- [Delete local snapshots \(p. 1826\)](#)
- [Automate snapshots on an Outpost \(p. 1826\)](#)

Rules for storing snapshots

The following rules apply to snapshot storage:

- If the most recent snapshot of a volume is stored on an Outpost, then all successive snapshots must be stored on the same Outpost.
- If the most recent snapshot of a volume is stored in an AWS Region, then all successive snapshots must be stored in the same Region. To start creating local snapshots from that volume, do the following:
 1. Create a snapshot of the volume in the AWS Region.
 2. Copy the snapshot to the Outpost from the AWS Region.
 3. Create a new volume from the local snapshot.
 4. Attach the volume to an instance on the Outpost.

For the new volume on the Outpost, the next snapshot can be stored on the Outpost or in the AWS Region. All successive snapshots must then be stored in that same location.

- Local snapshots, including snapshots created on an Outpost and snapshots copied to an Outpost from an AWS Region, can be used only to create volumes on the same Outpost.
- If you create a volume on an Outpost from a snapshot in a Region, then all successive snapshots of that new volume must be in the same Region.
- If you create a volume on an Outpost from a local snapshot, then all successive snapshots of that new volume must be on the same Outpost.

Create local snapshots from volumes on an Outpost

You can create local snapshots from volumes on your Outpost. You can choose to store the snapshots on the same Outpost as the source volume, or in the Region for the Outpost.

Local snapshots can be used to create volumes on the same Outpost only.

You can create local snapshots from volumes on an Outpost using one of the following methods.

Console

To create local snapshots from volumes on an Outpost

Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

1. In the navigation pane, choose **Volumes**.
2. Select the volume on the Outpost, and choose **Actions, Create Snapshot**.
3. (Optional) For **Description**, enter a brief description for the snapshot.
4. For **Snapshot destination**, choose **AWS Outpost**. The snapshot will be created on the same Outpost as the source volume. The **Outpost ARN** field shows the Amazon Resource Name (ARN) of the destination Outpost.
5. (Optional) Choose **Add Tag** to add tags to your snapshot. For each tag, provide a tag key and a tag value.
6. Choose **Create Snapshot**.

Command line

To create local snapshots from volumes on an Outpost

Use the [create-snapshot](#) command. Specify the ID of the volume from which to create the snapshot, and the ARN of the destination Outpost on which to store the snapshot. If you omit the Outpost ARN, the snapshot is stored in the AWS Region for the Outpost.

For example, the following command creates a local snapshot of volume `vol-1234567890abcdef0`, and stores the snapshot on Outpost `arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0`.

```
$ aws ec2 create-snapshot --volume-id vol-1234567890abcdef0 --outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0 --description "single volume local snapshot"
```

Create multi-volume local snapshots from instances on an Outpost

You can create crash-consistent multi-volume local snapshots from instances on your Outpost. You can choose to store the snapshots on the same Outpost as the source instance, or in the Region for the Outpost.

Multi-volume local snapshots can be used to create volumes on the same Outpost only.

You can create multi-volume local snapshots from instances on an Outpost using one of the following methods.

Console

To create multi-volume local snapshots from instances on an Outpost

Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

1. In the navigation pane, choose **Snapshots**.
2. Choose **Create Snapshot**.
3. For **Select resource type**, choose **Instance**.
4. For **Instance ID**, select the instance on the Outpost from which to create the snapshots.
5. (Optional) For **Description**, enter a brief description for the snapshots.
6. For **Snapshot destination**, choose **AWS Outpost**. The snapshots will be created on the same Outpost as the source instance. The **Outpost ARN** shows the ARN of the destination Outpost.
7. To exclude the instance's root volume from the multi-volume snapshot set, select **Exclude root volume**. If you do this, Amazon EBS will not create a snapshot of the instance's root volume.
8. To exclude specific data volumes from the multi-volume snapshot set, select **Exclude specific data volumes**. The **Attached data volumes** section lists all of the data volumes that are currently attached to the selected instance.

In the **Attached data volumes** section, deselect the data volumes to exclude from the multi-volume snapshot set. Only the volumes that remain selected will be included in the multi-volume snapshot set.

9. (Optional) To automatically copy tags from the source volumes to the corresponding snapshots, for **Copy tags from source volume**, select **Copy tags**. This sets snapshot metadata—such as access policies, attachment information, and cost allocation—to match the source volume.
10. (Optional) To assign additional custom tags to the snapshots, in the **Tags** section, choose **Add tag**, and then enter the key-value pair. You can add up to 50 tags.
11. Choose **Create Snapshot**.

During snapshot creation, the snapshots are managed together. If one of the snapshots in the volume set fails, the other snapshots in the volume set are moved to error status.

Command line

To create multi-volume local snapshots from instances on an Outpost

Use the [create-snapshots](#) command. Specify the ID of the instance from which to create the snapshots, and the ARN of the destination Outpost on which to store the snapshots. If you omit the Outpost ARN, the snapshots are stored in the AWS Region for the Outpost.

For example, the following command creates snapshots of the volumes attached to instance `i-1234567890abcdef0` and stores the snapshots on Outpost `arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0`.

```
$ aws ec2 create-snapshots --instance-specification InstanceId=i-1234567890abcdef0 --  
outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0 --  
description "multi-volume local snapshots"
```

Create AMIs from local snapshots

You can create Amazon Machine Images (AMIs) using a combination of local snapshots and snapshots that are stored in the Region of the Outpost. For example, if you have an Outpost in `us-east-1`, you can create an AMI with data volumes that are backed by local snapshots on that Outpost, and a root volume that is backed by a snapshot in the `us-east-1` Region.

Note

- You can't create AMIs that include backing snapshots stored across multiple Outposts.
- You can't currently create AMIs directly from instances on an Outposts using [CreateImage API](#) or the Amazon EC2 console for Outposts that are enabled with Amazon S3 on Outposts.
- AMIs that are backed by local snapshots can be used to launch instances on the same Outpost only.

To create an AMI on an Outpost from snapshots in a Region

1. Copy the snapshots from the Region to the Outpost. For more information, see [Copy snapshots from an AWS Region to an Outpost \(p. 1824\)](#).
2. Use the Amazon EC2 console or the [register-image](#) command to create the AMI using the snapshot copies on the Outpost. For more information, see [Creating an AMI from a snapshot](#).

To create an AMI on an Outpost from an instance on an Outpost

1. Create snapshots from the instance on the Outpost and store the snapshots on the Outpost. For more information, see [Create multi-volume local snapshots from instances on an Outpost \(p. 1823\)](#).
2. Use the Amazon EC2 console or the [register-image](#) command to create the AMI using the local snapshots. For more information, see [Creating an AMI from a snapshot](#).

To create an AMI in a Region from an instance on an Outpost

1. Create snapshots from the instance on the Outpost and store the snapshots in the Region. For more information, see [Create local snapshots from volumes on an Outpost \(p. 1822\)](#) or [Create multi-volume local snapshots from instances on an Outpost \(p. 1823\)](#).
2. Use the Amazon EC2 console or the [register-image](#) command to create the AMI using the snapshot copies in the Region. For more information, see [Creating an AMI from a snapshot](#).

Copy snapshots from an AWS Region to an Outpost

You can copy snapshots from an AWS Region to an Outpost. You can do this only if the snapshots are in the Region for the Outpost. If the snapshots are in a different Region, you must first copy the snapshot to the Region for the Outpost, and then copy it from that Region to the Outpost.

Note

You can't copy local snapshots from an Outpost to a Region, from one Outpost to another, or within the same Outpost.

You can copy snapshots from a Region to an Outpost using one of the following methods.

Console

To copy a snapshot from an AWS Region to an Outpost

Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

1. In the navigation pane, choose **Snapshots**.
2. Select the snapshot in the Region, and choose **Actions, Copy**.
3. For **Destination Region**, choose the Region for the destination Outpost.
4. For **Snapshot Destination**, choose **AWS Outpost**.

The **Snapshot Destination** field only appears if you have Outposts in the selected destination Region. If the field does not appear, you do not have any Outposts in the selected destination Region.

5. For **Destination Outpost ARN**, enter the ARN of the Outpost to which to copy the snapshot.
6. (Optional) For **Description**, enter a brief description of the copied snapshot.
7. Encryption is enabled by default for the snapshot copy. Encryption cannot be disabled. For **KMS key**, choose the KMS key to use.
8. Choose **Copy**.

Command line

To copy a snapshot from a Region to an Outpost

Use the [copy-snapshot](#) command. Specify the ID of the snapshot to copy, the Region from which to copy the snapshot, and the ARN of the destination Outpost.

For example, the following command copies snapshot snap-1234567890abcdef0 from the us-east-1 Region to Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0.

```
$ aws ec2 copy-snapshot --source-region us-east-1 --source-snapshot-id snap-1234567890abcdef0 --destination-outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0 --description "Local snapshot copy"
```

[Copy AMIs from an AWS Region to an Outpost](#)

You can copy AMIs from an AWS Region to an Outpost. When you copy an AMI from a Region to an Outpost, all of the snapshots associated with the AMI are copied from the Region to the Outpost.

You can copy an AMI from a Region to an Outpost only if the snapshots associated with the AMI are in the Region for the Outpost. If the snapshots are in a different Region, you must first copy the AMI to the Region for the Outpost, and then copy it from that Region to the Outpost.

Note

You can't copy an AMI from an Outpost to a Region, from one Outpost to another, or within an Outpost.

You can copy AMIs from a Region to an Outpost using the AWS CLI only.

Command line

To copy an AMI from a Region to an Outpost

Use the [copy-image](#) command. Specify the ID of the AMI to copy, the source Region, and the ARN of the destination Outpost.

For example, the following command copies AMI ami-1234567890abcdef0 from the us-east-1 Region to Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0.

```
$ aws ec2 copy-image --source-region us-east-1 --source-image-id ami-1234567890abcdef0
--name "Local AMI copy" --destination-outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0
```

Create volumes from local snapshots

You can create volumes on Outposts from local snapshots. Volumes must be created on the same Outpost as the source snapshots. You cannot use local snapshots to create volumes in the Region for the Outpost.

When you create a volume from a local snapshot, you cannot re-encrypt the volume using different KMS key. Volumes created from local snapshots must be encrypted using the same KMS key as the source snapshot.

For more information, see [Create a volume from a snapshot \(p. 1728\)](#).

Launch instances from AMIs backed by local snapshots

You can launch instances from AMIs that are backed by local snapshots. You must launch Instances on the same Outpost as the source AMI. For more information, see [Launch an instance on your Outpost](#) in the *AWS Outposts User Guide*.

Delete local snapshots

You can delete local snapshots from an Outpost. After you delete a snapshot from an Outpost, the Amazon S3 storage capacity used by the deleted snapshot becomes available within 72 hours after deleting the snapshot and the volumes that reference that snapshot.

Because Amazon S3 storage capacity does not become available immediately, we recommend that you use Amazon CloudWatch alarms to monitor your Amazon S3 storage capacity. Delete snapshots and volumes that you no longer need to avoid running out of storage capacity.

For more information about deleting snapshots, see [Delete a snapshot \(p. 1781\)](#).

Automate snapshots on an Outpost

You can create Amazon Data Lifecycle Manager snapshot lifecycle policies that automatically create, copy, retain, and delete snapshots of your volumes and instances on an Outpost. You can choose whether to store the snapshots in a Region or whether to store them locally on an Outpost. Additionally, you can automatically copy snapshots that are created and stored in an AWS Region to an Outpost.

The following table shows provides an Overview of the supported features.

Resource location	Snapshot destination	Cross-region copy	Fast snapshot restore	Cross-account sharing
		To Region	To Outpost	

Region	Region	✓	✓	✓	✓
Outpost	Region	✓	✓	✓	✓
Outpost	Outpost	✗	✗	✗	✗

Considerations

- Only Amazon EBS snapshot lifecycle policies are currently supported. EBS-backed AMI policies and Cross-account sharing event policies are not supported.
- If a policy manages snapshots for volumes or instances in a Region, then snapshots are created in the same Region as the source resource.
- If a policy manages snapshots for volumes or instances on an Outpost, then snapshots can be created on the source Outpost, or in the Region for that Outpost.
- A single policy can't manage both snapshots in a Region and snapshots on an Outpost. If you need to automate snapshots in a Region and on an Outpost, you must create separate policies.
- Fast snapshot restore is not supported for snapshots created on an Outpost, or for snapshots copied to an Outpost.
- Cross-account sharing is not supported for snapshots created on an Outpost.

For more information about creating a snapshot lifecycle that manages local snapshots, see [Automating snapshot lifecycles \(p. 1862\)](#).

Use EBS direct APIs to access the contents of an EBS snapshot

You can use the Amazon Elastic Block Store (Amazon EBS) direct APIs to create EBS snapshots, write data directly to your snapshots, read data on your snapshots, and identify the differences or changes between two snapshots. If you're an independent software vendor (ISV) who offers backup services for Amazon EBS, the EBS direct APIs make it more efficient and cost-effective to track incremental changes on your EBS volumes through snapshots. This can be done without having to create new volumes from snapshots, and then use Amazon Elastic Compute Cloud (Amazon EC2) instances to compare the differences.

You can create incremental snapshots directly from data on-premises into EBS volumes and the cloud to use for quick disaster recovery. With the ability to write and read snapshots, you can write your on-premises data to an EBS snapshot during a disaster. Then after recovery, you can restore it back to AWS or on-premises from the snapshot. You no longer need to build and maintain complex mechanisms to copy data to and from Amazon EBS.

This user guide provides an overview of the elements that make up the EBS direct APIs, and examples of how to use them effectively. For more information about the actions, data types, parameters, and errors of the APIs, see the [EBS direct APIs reference](#). For more information about the supported AWS Regions, endpoints, and service quotas for the EBS direct APIs, see [Amazon EBS Endpoints and Quotas](#) in the [AWS General Reference](#).

Contents

- [Understand the EBS direct APIs \(p. 1828\)](#)
- [IAM permissions for EBS direct APIs \(p. 1829\)](#)
- [Use EBS direct APIs \(p. 1833\)](#)
- [Pricing for EBS direct APIs \(p. 1851\)](#)
- [Using interface VPC endpoints with EBS direct APIs \(p. 1852\)](#)
- [Log API Calls for EBS direct APIs with AWS CloudTrail \(p. 1852\)](#)
- [Frequently asked questions \(p. 1858\)](#)

Understand the EBS direct APIs

The following are the key elements that you should understand before getting started with the EBS direct APIs.

Snapshots

Snapshots are the primary means to back up data from your EBS volumes. With the EBS direct APIs, you can also back up data from your on-premises disks to snapshots. To save storage costs, successive snapshots are incremental, containing only the volume data that changed since the previous snapshot. For more information, see [Amazon EBS snapshots \(p. 1757\)](#).

Note

EBS direct APIs does not support public snapshots and local snapshots on Outposts.

Blocks

A block is a fragment of data within a snapshot. Each snapshot can contain thousands of blocks. All blocks in a snapshot are of a fixed size.

Block indexes

A block index is a logical index in units of 512 KiB blocks. To identify the block index, divide the logical offset of the data in the logical volume by the block size (logical offset of data/524288). The logical offset of the data must be 512 KiB aligned.

Block tokens

A block token is the identifying hash of a block within a snapshot, and it is used to locate the block data. Block tokens returned by EBS direct APIs are temporary. They change on the expiry timestamp specified for them, or if you run another `ListSnapshotBlocks` or `ListChangedBlocks` request for the same snapshot.

Checksum

A checksum is a small-sized datum derived from a block of data for the purpose of detecting errors that were introduced during its transmission or storage. The EBS direct APIs use checksums to validate data integrity. When you read data from an EBS snapshot, the service provides Base64-encoded SHA256 checksums for each block of data transmitted, which you can use for validation. When you write data to an EBS snapshot, you must provide a Base64 encoded SHA256 checksum for each block of data transmitted. The service validates the data received using the checksum provided. For more information, see [Use checksums \(p. 1845\)](#) later in this guide.

Encryption

Encryption protects your data by converting it into unreadable code that can be deciphered only by people who have access to the KMS key used to encrypt it. You can use the EBS direct APIs to read and write encrypted snapshots, but there are some limitations. For more information, see [Use encryption \(p. 1843\)](#) later in this guide.

API actions

The EBS direct APIs consists of six actions. There are three read actions and three write actions. The read actions are:

- **ListSnapshotBlocks** — returns the block indexes and block tokens of blocks in the specified snapshot
- **ListChangedBlocks** — returns the block indexes and block tokens of blocks that are different between two specified snapshots of the same volume and snapshot lineage.
- **GetSnapshotBlock** — returns the data in a block for the specified snapshot ID, block index, and block token.

The write actions are:

- **StartSnapshot** — starts a snapshot, either as an incremental snapshot of an existing one or as a new snapshot. The started snapshot remains in a pending state until it is completed using the CompleteSnapshot action.
- **PutSnapshotBlock** — adds data to a started snapshot in the form of individual blocks. You must specify a Base64-encoded SHA256 checksum for the block of data transmitted. The service validates the checksum after the transmission is completed. The request fails if the checksum computed by the service doesn't match what you specified.
- **CompleteSnapshot** — completes a started snapshot that is in a pending state. The snapshot is then changed to a completed state.

IAM permissions for EBS direct APIs

A user must have the following policies to use the EBS direct APIs. For more information, see [Changing permissions for a user](#).

For more information about the EBS direct APIs resources, actions, and condition context keys for use in IAM permission policies, see [Actions, resources, and condition keys for Amazon Elastic Block Store](#) in the *Service Authorization Reference*.

Important

Be cautious when assigning the following policies to users. By assigning these policies, you might give access to a user who is denied access to the same resource through the Amazon EC2 APIs, such as the CopySnapshot or CreateVolume actions.

Permissions to read snapshots

The following policy allows the *read* EBS direct APIs to be used on all snapshots in a specific AWS Region. In the policy, replace `<Region>` with the Region of the snapshot.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ebs>ListSnapshotBlocks",  
                "ebs>ListChangedBlocks",  
                "ebs>GetSnapshotBlock"  
            ],  
            "Resource": "arn:aws:ec2:<Region>::snapshot/*"  
        }  
    ]  
}
```

The following policy allows the *read* EBS direct APIs to be used on snapshots with a specific key-value tag. In the policy, replace `<Key>` with the key value of the tag, and `<Value>` with the value of the tag.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ebs>ListSnapshotBlocks",  
                "ebs>ListChangedBlocks",  
                "ebs>GetSnapshotBlock"  
            ],  
            "Resource": "arn:aws:ec2:*:snapshot/*",  
            "Condition": {  
                "StringEqualsIgnoreCase": {  
                    "tag:Key": "<Value>"  
                }  
            }  
        }  
    ]  
}
```

```
        "aws:ResourceTag/<Key>": "<Value>"  
    }  
}  
]  
}
```

The following policy allows all of the *read* EBS direct APIs to be used on all snapshots in the account only within a specific time range. This policy authorizes use of the EBS direct APIs based on the `aws:CurrentTime` global condition key. In the policy, be sure to replace the date and time range shown with the date and time range for your policy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ebs>ListSnapshotBlocks",  
                "ebs>ListChangedBlocks",  
                "ebs>GetSnapshotBlock"  
            ],  
            "Resource": "arn:aws:ec2*:snapshot/*",  
            "Condition": {  
                "DateGreaterThan": {  
                    "aws:CurrentTime": "2018-05-29T00:00:00Z"  
                },  
                "DateLessThan": {  
                    "aws:CurrentTime": "2020-05-29T23:59:59Z"  
                }  
            }  
        }  
    ]  
}
```

For more information, see [Changing permissions for a user](#) in the *IAM User Guide*.

Permissions to write snapshots

The following policy allows the *write* EBS direct APIs to be used on all snapshots in a specific AWS Region. In the policy, replace `<Region>` with the Region of the snapshot.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ebs>StartSnapshot",  
                "ebs>PutSnapshotBlock",  
                "ebs>CompleteSnapshot"  
            ],  
            "Resource": "arn:aws:ec2:<Region>:snapshot/*"  
        }  
    ]  
}
```

The following policy allows the *write* EBS direct APIs to be used on snapshots with a specific key-value tag. In the policy, replace `<Key>` with the key value of the tag, and `<Value>` with the value of the tag.

```
{  
    "Version": "2012-10-17",  
}
```

```
"Statement": [
    {
        "Effect": "Allow",
        "Action": [
            "ebs:StartSnapshot",
            "ebs:PutSnapshotBlock",
            "ebs:CompleteSnapshot"
        ],
        "Resource": "arn:aws:ec2:*::snapshot/*",
        "Condition": {
            "StringEqualsIgnoreCase": {
                "aws:ResourceTag/<Key>": "<Value>"
            }
        }
    }
]
```

The following policy allows all of the EBS direct APIs to be used. It also allows the StartSnapshot action only if a parent snapshot ID is specified. Therefore, this policy blocks the ability to start new snapshots without using a parent snapshot.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ebs:*",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "ebs:ParentSnapshot": "arn:aws:ec2:*::snapshot/*"
                }
            }
        }
    ]
}
```

The following policy allows all of the EBS direct APIs to be used. It also allows only the user tag key to be created for a new snapshot. This policy also ensures that the user has access to create tags. The StartSnapshot action is the only action that can specify tags.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ebs:*",
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringEquals": {
                    "aws:TagKeys": "user"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
    ]
}
```

The following policy allows all of the *write* EBS direct APIs to be used on all snapshots in the account only within a specific time range. This policy authorizes use of the EBS direct APIs based on the `aws:CurrentTime` global condition key. In the policy, be sure to replace the date and time range shown with the date and time range for your policy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ebs:StartSnapshot",  
                "ebs:PutSnapshotBlock",  
                "ebs:CompleteSnapshot"  
            ],  
            "Resource": "arn:aws:ec2:*::snapshot/*",  
            "Condition": {  
                "DateGreaterThan": {  
                    "aws:CurrentTime": "2018-05-29T00:00:00Z"  
                },  
                "DateLessThan": {  
                    "aws:CurrentTime": "2020-05-29T23:59:59Z"  
                }  
            }  
        }  
    ]  
}
```

For more information, see [Changing permissions for a user](#) in the *IAM User Guide*.

Permissions to use AWS KMS keys

The following policy grants permission to decrypt an encrypted snapshot using a specific KMS key. It also grants permission to encrypt new snapshots using the default KMS key for EBS encryption. In the policy, replace `<Region>` with the Region of the KMS key, `<AccountId>` with the ID of the AWS account of the KMS key, and `<KeyId>` with the ID of the KMS key.

Note

By default, all principals in the account have access to the default AWS managed KMS key for Amazon EBS encryption, and they can use it for EBS encryption and decryption operations. If you are using a customer managed key, you must create a new key policy or modify the existing key policy for the customer managed key to grant the principal access to the customer managed key. For more information, see [Key policies in AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

Tip

To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the `kms:GrantIsForAWSResource` condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "VisualEditor0",  
            "Effect": "Allow",  
            "Action": [  
                "kms:Encrypt",  
                "kms:Decrypt",  
                "kms:GenerateDataKey",  
                "kms:GenerateDataKeyWithoutPlaintext",  
            ]  
        }  
    ]  
}
```

```
        "kms:ReEncrypt*",
        "kms>CreateGrant",
        "ec2>CreateTags",
        "kms:DescribeKey"
    ],
    "Resource": "arn:aws:kms:<Region>:<AccountId>:key/<KeyId>",
    "Condition": {
        "Bool": {
            "kms:GrantIsForAWSResource": true
        }
    }
}
]
```

For more information, see [Changing permissions for a user](#) in the *IAM User Guide*.

Use EBS direct APIs

The following topics show how to read and write snapshots using the EBS direct APIs. You can read and write snapshots using the AWS CLI, AWS APIs, and AWS SDKs only. For more information, see:

- [Installing the AWS CLI](#) and [Configuring the AWS CLI](#)
- [EBS direct APIs Reference](#)
- [AWS SDKs](#)

Important

The EBS direct APIs require an AWS Signature Version 4 signature. For more information, see [Use Signature Version 4 signing \(p. 1845\)](#).

Topics

- [Read snapshots with EBS direct APIs \(p. 1833\)](#)
- [Write snapshots with EBS direct APIs \(p. 1839\)](#)
- [Use encryption \(p. 1843\)](#)
- [Use Signature Version 4 signing \(p. 1845\)](#)
- [Use checksums \(p. 1845\)](#)
- [Idempotency for StartSnapshot API \(p. 1846\)](#)
- [Error retries \(p. 1846\)](#)
- [Optimize performance \(p. 1848\)](#)
- [EBS direct APIs service endpoints \(p. 1848\)](#)

Read snapshots with EBS direct APIs

The following steps describe how to use the EBS direct APIs to read snapshots:

1. Use the `ListSnapshotBlocks` action to view all block indexes and block tokens of blocks in a snapshot. Or use the `ListChangedBlocks` action to view only the block indexes and block tokens of blocks that are different between two snapshots of the same volume and snapshot lineage. These actions help you identify the block tokens and block indexes of blocks for which you might want to get data.
2. Use the `GetSnapshotBlock` action, and specify the block index and block token of the block for which you want to get data.

The following examples show how to read snapshots using the EBS direct APIs.

Topics

- [List blocks in a snapshot \(p. 1834\)](#)
- [List blocks that are different between two snapshots \(p. 1835\)](#)
- [Get block data from a snapshot \(p. 1838\)](#)

List blocks in a snapshot

AWS CLI

The following [list-snapshot-blocks](#) example command returns the block indexes and block tokens of blocks that are in snapshot snap-0987654321. The --starting-block-index parameter limits the results to block indexes greater than 1000, and the --max-results parameter limits the results to the first 100 blocks.

```
aws ebs list-snapshot-blocks --snapshot-id snap-0987654321 --starting-block-index 1000  
--max-results 100
```

The following example response for the previous command lists the block indexes and block tokens in the snapshot. Use the get-snapshot-block command and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```
{  
    "Blocks": [  
        {  
            "BlockIndex": 1001,  
            "BlockToken": "AAABAV3/  
PNhX0ynVdMYHUpPsetaSvjLB1dtIGfbJv50J0sX855EzGTWos4a4"  
        },  
        {  
            "BlockIndex": 1002,  
            "BlockToken": "AAABATGQIgwr0WwIuqIMjCA/Sy7e/  
YoQFZsHejzGNvjKauzNgzeI13YHBFQB"  
        },  
        {  
            "BlockIndex": 1007,  
            "BlockToken": "AAABA9CTuQtUvp/  
dXqRWw4d07e0gTZ3jvn6hiW30W9duM8MiMw6yQayzF2c"  
        },  
        {  
            "BlockIndex": 1012,  
            "BlockToken": "AAABAQdzxhw0rVV6PNmsfo/  
YRlxo9JPR85XxPf1BLjg0Hec6pygYr6laE1p0"  
        },  
        {  
            "BlockIndex": 1030,  
            "BlockToken": "AAABAAyvPax6mv+iGWLdTujQtFWouQ7Dqz6nSD9L  
+CbXnpkswA6iDID523d"  
        },  
        {  
            "BlockIndex": 1031,  
            "BlockToken": "AAABATgWZC0XcFwUKvTJbUXMiSPg59KVxJGL  
+BWBC1kw6spzCxJVqDVaTskJ"  
        },  
        ...  
    ],  
    "ExpiryTime": 1576287332.806,  
    "VolumeSize": 32212254720,  
    "BlockSize": 524288  
}
```

AWS API

The following [ListSnapshotBlocks](#) example request returns the block indexes and block tokens of blocks that are in snapshot snap-0acEXAMPLEcf41648. The `startingBlockIndex` parameter limits the results to block indexes greater than 1000, and the `maxResults` parameter limits the results to the first 100 blocks.

```
GET /snapshots/snap-0acEXAMPLEcf41648/blocks?maxResults=100&startingBlockIndex=1000
HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
User-Agent: <User agent parameter>
X-Amz-Date: 20200617T231953Z
Authorization: <Authentication parameter>
```

The following example response for the previous request lists the block indexes and block tokens in the snapshot. Use the `GetSnapshotBlock` action and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```
HTTP/1.1 200 OK
x-amzn-RequestId: d6e5017c-70a8-4539-8830-57f5557f3f27
Content-Type: application/json
Content-Length: 2472
Date: Wed, 17 Jun 2020 23:19:56 GMT
Connection: keep-alive

{
    "BlockSize": 524288,
    "Blocks": [
        {
            "BlockIndex": 0,
            "BlockToken": "AAUBAcuWqOCnDNuKle11s7IIx6jp6FYcC/q8oT93913HhvLvA
+3JRrSybp/0"
        },
        {
            "BlockIndex": 1536,

        },
        ...
    ],
    "ExpiryTime": 1.59298379649E9,
    "VolumeSize": 3
}
```

List blocks that are different between two snapshots

Keep the following in mind when making **paginated requests** to list the changed blocks between two snapshots:

- The response can include one or more empty `ChangedBlocks` arrays. For example:

- Snapshot 1 — full snapshot with 1000 blocks with block indexes 0 - 999.
- Snapshot 2 — incremental snapshot with only one changed block with block index 999.

Listing the changed blocks for these snapshots with StartingBlockIndex = 0 and MaxResults = 100 returns an empty array of ChangedBlocks. You must request the remaining results using nextToken until the changed block is returned in the tenth result set, which includes blocks with block indexes 900 - 999.

- The response can skip unwritten blocks in the snapshots. For example:
 - Snapshot 1 — full snapshot with 1000 blocks with block indexes 2000 - 2999.
 - Snapshot 2 — incremental snapshot with only one changed block with block index 2000.

Listing the changed blocks for these snapshots with StartingBlockIndex = 0 and MaxResults = 100, the response skips block indexes 0 - 1999 and includes block index 2000. The response will not include empty ChangedBlocks arrays.

AWS CLI

The following [list-changed-blocks](#) example command returns the block indexes and block tokens of blocks that are different between snapshots snap-1234567890 and snap-0987654321. The --starting-block-index parameter limits the results to block indexes greater than 0, and the --max-results parameter limits the results to the first 500 blocks..

```
aws ebs list-changed-blocks --first-snapshot-id snap-1234567890 --second-snapshot-id snap-0987654321 --starting-block-index 0 --max-results 500
```

The following example response for the previous command shows that block indexes 0, 6000, 6001, 6002, and 6003 are different between the two snapshots. Additionally, block indexes 6001, 6002, and 6003 exist only in the first snapshot ID specified, and not in the second snapshot ID because there is no second block token listed in the response.

Use the get-snapshot-block command and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```
{
    "ChangedBlocks": [
        {
            "BlockIndex": 0,
            "FirstBlockToken": "AAABA Vahm9S060Dyi00RySzn2ZjGjW/

}
```

AWS API

The following [ListChangedBlocks](#) example request returns the block indexes and block tokens of blocks that are different between snapshots snap-0acEXAMPLEcf41648 and snap-0c9EXAMPLE1b30e2f. The startingBlockIndex parameter limits the results to block indexes greater than 0, and the maxResults parameter limits the results to the first 500 blocks.

```
GET /snapshots/snap-0c9EXAMPLE1b30e2f/changedblocks?  
firstSnapshotId=snap-0acEXAMPLEcf41648&maxResults=500&startingBlockIndex=0 HTTP/1.1  
Host: ebs.us-east-2.amazonaws.com  
Accept-Encoding: identity  
User-Agent: <User agent parameter>  
X-Amz-Date: 20200617T232546Z  
Authorization: <Authentication parameter>
```

The following example response for the previous request shows that block indexes 0, 3072, 6002, and 6003 are different between the two snapshots. Additionally, block indexes 6002, and 6003 exist only in the first snapshot ID specified, and not in the second snapshot ID because there is no second block token listed in the response.

Use the GetSnapshotBlock action and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```
HTTP/1.1 200 OK

```

Get block data from a snapshot

AWS CLI

The following [get-snapshot-block](#) example command returns the data in the block index 6001 with block token AAABASBpSJ2UAD3PLxJnCt6zun4/T4sU25Bnb8jB5Q6FRXHFqAIaqE04hJoR, in snapshot snap-1234567890. The binary data is output to the data file in the C:\Temp directory on a Windows computer. If you run the command on a Linux or Unix computer, replace the output path with /tmp/data to output the data to the data file in the /tmp directory.

```
aws ebs get-snapshot-block --snapshot-id snap-1234567890 --block-index 6001 --block-token AAABASBpSJ2UAD3PLxJnCt6zun4/T4sU25Bnb8jB5Q6FRXHFqAIaqE04hJoR C:/Temp/data
```

The following example response for the previous command shows the size of the data returned, the checksum to validate the data, and the algorithm of the checksum. The binary data is automatically saved to the directory and file you specified in the request command.

```
{  
    "DataLength": "524288",  
    "Checksum": "cf0Y6/Fn0oFa4VvjQP0a/iD0zhTf1PTKzxGv20KowXc=",  
    "ChecksumAlgorithm": "SHA256"  
}
```

AWS API

The following [GetSnapshotBlock](#) example request returns the data in the block index 3072 with block token AAUBARGCaufCqBRZC8tEkPYGGkSv3vqv0jJ2xKDijDFiytUxBLXYgTmkid, in snapshot snap-0c9EXAMPLE1b30e2f.

```
GET /snapshots/snap-0c9EXAMPLE1b30e2f(blocks/3072?  
blockToken=AAUBARGCaufCqBRZC8tEkPYGGkSv3vqv0jJ2xKDijDFiytUxBLXYgTmkid HTTP/1.1  
Host: ebs.us-east-2.amazonaws.com  
Accept-Encoding: identity  
User-Agent: <User agent parameter>  
X-Amz-Date: 20200617T232838Z  
Authorization: <Authentication parameter>
```

The following example response for the previous request shows the size of the data returned, the checksum to validate the data, and the algorithm used to generate the checksum. The binary data is transmitted in the body of the response and is represented as *BlockData* in the following example.

```
HTTP/1.1 200 OK  
x-amzn-RequestId: 2d0db2fb-bd88-474d-a137-81c4e57d7b9f  
x-amz-Data-Length: 524288  
x-amz-Checksum: Vc0yY2j3qg8bUL9I6GQuI2orTudrQRBDMIhcy7bdEsw=
```

```
x-amz-Checksum-Algorithm: SHA256
Content-Type: application/octet-stream
Content-Length: 524288
Date: Wed, 17 Jun 2020 23:28:38 GMT
Connection: keep-alive
```

BlockData

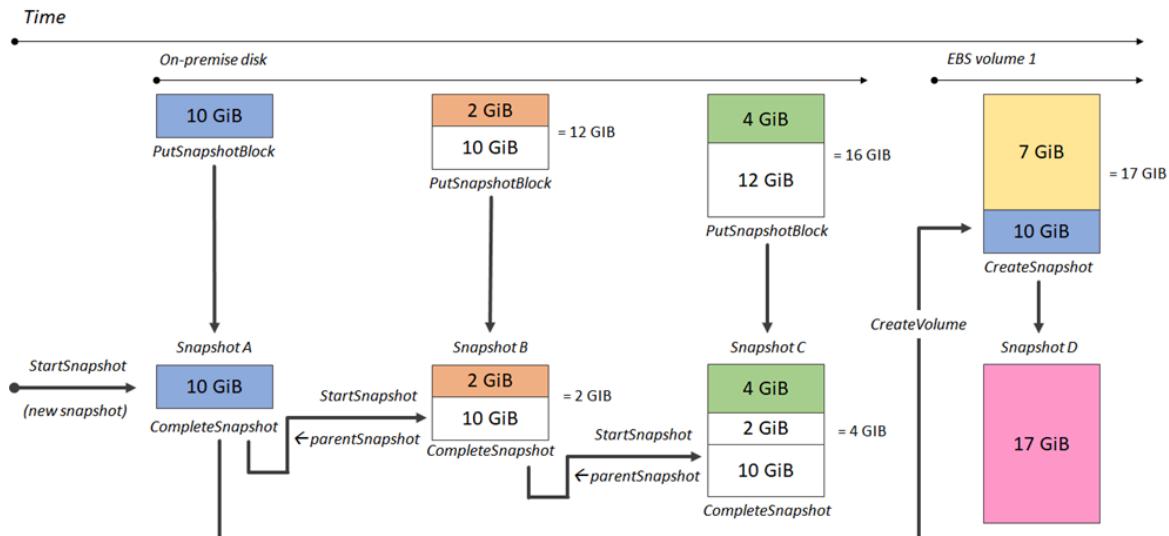

Write snapshots with EBS direct APIs

The following steps describe how to use the EBS direct APIs to write incremental snapshots:

1. Use the `StartSnapshot` action and specify a parent snapshot ID to start a snapshot as an incremental snapshot of an existing one, or omit the parent snapshot ID to start a new snapshot. This action returns the new snapshot ID, which is in a pending state.
2. Use the `PutSnapshotBlock` action and specify the ID of the pending snapshot to add data to it in the form of individual blocks. You must specify a Base64-encoded SHA256 checksum for the block of data transmitted. The service computes the checksum of the data received and validates it with the checksum that you specified. The action fails if the checksums don't match.
3. When you're done adding data to the pending snapshot, use the `CompleteSnapshot` action to start an asynchronous workflow that seals the snapshot and moves it to a completed state.

Repeat these steps to create a new, incremental snapshot using the previously created snapshot as the parent.

For example, in the following diagram, snapshot A is the first new snapshot started. Snapshot A is used as the parent snapshot to start snapshot B. Snapshot B is used as the parent snapshot to start and create snapshot C. Snapshots A, B, and C are incremental snapshots. Snapshot A is used to create EBS volume 1. Snapshot D is created from EBS volume 1. Snapshot D is an incremental snapshot of A; it is not an incremental snapshot of B or C.

The following examples show how to write snapshots using the EBS direct APIs.

Topics

- [Start a snapshot \(p. 1840\)](#)
- [Put data into a snapshot \(p. 1841\)](#)
- [Complete a snapshot \(p. 1842\)](#)

Start a snapshot

AWS CLI

The following [start-snapshot](#) example command starts an 8 GiB snapshot, using snapshot `snap-123EXAMPLE1234567` as the parent snapshot. The new snapshot will be an incremental snapshot of the parent snapshot. The snapshot moves to an error state if there are no put or complete requests made for the snapshot within the specified 60 minute timeout period. The `550e8400-e29b-41d4-a716-446655440000` client token ensures idempotency for the request. If the client token is omitted, the AWS SDK automatically generates one for you. For more information about idempotency, see [Idempotency for StartSnapshot API \(p. 1846\)](#).

```
aws ebs start-snapshot --volume-size 8 --parent-snapshot snap-123EXAMPLE1234567 --  
timeout 60 --client-token 550e8400-e29b-41d4-a716-446655440000
```

The following example response for the previous command shows the snapshot ID, AWS account ID, status, volume size in GiB, and size of the blocks in the snapshot. The snapshot is started in a pending state. Specify the snapshot ID in subsequent `put-snapshot-block` commands to write data to the snapshot, then use the `complete-snapshot` command to complete the snapshot and change its status to completed.

```
{  
    "SnapshotId": "snap-0aaEXAMPLEe306d62",  
    "OwnerId": "111122223333",  
    "Status": "pending",  
    "VolumeSize": 8,  
    "BlockSize": 524288  
}
```

AWS API

The following [StartSnapshot](#) example request starts an 8 GiB snapshot, using snapshot `snap-123EXAMPLE1234567` as the parent snapshot. The new snapshot will be an incremental snapshot of the parent snapshot. The snapshot moves to an error state if there are no put or complete requests made for the snapshot within the specified 60 minute timeout period. The `550e8400-e29b-41d4-a716-446655440000` client token ensures idempotency for the request. If the client token is omitted, the AWS SDK automatically generates one for you. For more information about idempotency, see [Idempotency for StartSnapshot API \(p. 1846\)](#).

```
POST /snapshots HTTP/1.1  
Host: ebs.us-east-2.amazonaws.com  
Accept-Encoding: identity  
User-Agent: <User agent parameter>  
X-Amz-Date: 20200618T040724Z  
Authorization: <Authentication parameter>  
  
{  
    "VolumeSize": 8,  
    "ParentSnapshot": snap-123EXAMPLE1234567,  
    "ClientToken": "550e8400-e29b-41d4-a716-446655440000",  
    "Timeout": 60  
}
```

The following example response for the previous request shows the snapshot ID, AWS account ID, status, volume size in GiB, and size of the blocks in the snapshot. The snapshot is started in a pending state. Specify the snapshot ID in a subsequent `PutSnapshotBlocks` request to write data to the snapshot.

```
HTTP/1.1 201 Created
```

```
x-amzn-RequestId: 929e6eb9-7183-405a-9502-5b7da37c1b18
Content-Type: application/json
Content-Length: 181
Date: Thu, 18 Jun 2020 04:07:29 GMT
Connection: keep-alive

{
    "BlockSize": 524288,
    "Description": null,
    "OwnerId": "138695307491",
    "Progress": null,
    "SnapshotId": "snap-052EXAMPLEc85d8dd",
    "StartTime": null,
    "Status": "pending",
    "Tags": null,
    "VolumeSize": 8
}
```

Put data into a snapshot

AWS CLI

The following [put-snapshot](#) example command writes 524288 Bytes of data to block index 1000 on snapshot snap-0aaEXAMPLEe306d62. The Base64 encoded QOD3gmEQOXATfJx2Aa34W4FU2nZGyXfqtsUukt0w8DM= checksum was generated using the SHA256 algorithm. The data that is transmitted is in the /tmp/data file.

```
aws ebs put-snapshot-block --snapshot-id snap-0aaEXAMPLEe306d62
--block-index 1000 --data-length 524288 --block-data /tmp/data --
checksum QOD3gmEQOXATfJx2Aa34W4FU2nZGyXfqtsUukt0w8DM= --checksum-algorithm SHA256
```

The following example response for the previous command confirms the data length, checksum, and checksum algorithm for the data received by the service.

```
{
    "DataLength": "524288",
    "Checksum": "QOD3gmEQOXATfJx2Aa34W4FU2nZGyXfqtsUukt0w8DM=",
    "ChecksumAlgorithm": "SHA256"
}
```

AWS API

The following [PutSnapshot](#) example request writes 524288 Bytes of data to block index 1000 on snapshot snap-052EXAMPLEc85d8dd. The Base64 encoded QOD3gmEQOXATfJx2Aa34W4FU2nZGyXfqtsUukt0w8DM= checksum was generated using the SHA256 algorithm. The data is transmitted in the body of the request and is represented as *BlockData* in the following example.

```
PUT /snapshots/snap-052EXAMPLEc85d8dd(blocks)/1000 HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
x-amz-Data-Length: 524288
x-amz-C checksum: QOD3gmEQOXATfJx2Aa34W4FU2nZGyXfqtsUukt0w8DM=
x-amz-C checksum-Algorithm: SHA256
User-Agent: <User agent parameter>
X-Amz-Date: 20200618T042215Z
X-Amz-Content-SHA256: UNSIGNED-PAYOUT
Authorization: <Authentication parameter>
```

BlockData

The following is example response for the previous request confirms the data length, checksum, and checksum algorithm for the data received by the service.

```
HTTP/1.1 201 Created
x-amzn-RequestId: 643ac797-7e0c-4ad0-8417-97b77b43c57b
x-amz-C checksum: Q0D3gmEQ0XATfJx2Aa34W4FU2nZGyXfqtsUukt0w8DM=
x-amz-C checksum-Algorithm: SHA256
Content-Type: application/json
Content-Length: 2
Date: Thu, 18 Jun 2020 04:22:12 GMT
Connection: keep-alive

{}
```

Complete a snapshot

AWS CLI

The following [complete-snapshot](#) example command completes snapshot snap-0aaEXAMPLEe306d62. The command specifies that 5 blocks were written to the snapshot. The 6D3nmwi5f2F0wlh7xX8QprrJBFzDX8aacd0cA3KCM3c= checksum represents the checksum for the complete set of data written to a snapshot. For more information about checksums, see [Use checksums \(p. 1845\)](#) earlier in this guide.

```
aws ebs complete-snapshot --snapshot-id snap-0aaEXAMPLEe306d62 --changed-blocks-count 5
--checksum 6D3nmwi5f2F0wlh7xX8QprrJBFzDX8aacd0cA3KCM3c= --checksum-algorithm SHA256 --
checksum-aggregation-method LINEAR
```

The following is an example response for the previous command.

```
{ "Status": "pending" }
```

AWS API

The following [CompleteSnapshot](#) example request completes snapshot snap-052EXAMPLEc85d8dd. The command specifies that 5 blocks were written to the snapshot. The 6D3nmwi5f2F0wlh7xX8QprrJBFzDX8aacd0cA3KCM3c= checksum represents the checksum for the complete set of data written to a snapshot.

```
POST /snapshots/completion/snap-052EXAMPLEc85d8dd HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
x-amz-ChangedBlocksCount: 5
x-amz-C checksum: 6D3nmwi5f2F0wlh7xX8QprrJBFzDX8aacd0cA3KCM3c=
x-amz-C checksum-Algorithm: SHA256
x-amz-C checksum-Aggregation-Method: LINEAR
User-Agent: <User agent parameter>
X-Amz-Date: 20200618T043158Z
Authorization: <Authentication parameter>
```

The following is an example response for the previous request.

```
HTTP/1.1 202 Accepted
x-amzn-RequestId: 06cba5b5-b731-49de-af40-80333ac3a117
```

```
Content-Type: application/json
Content-Length: 20
Date: Thu, 18 Jun 2020 04:31:50 GMT
Connection: keep-alive

{"Status": "pending"}
```

Use encryption

When you start a new snapshot using [StartSnapshot](#), the encryption status depends on the values that you specify for **Encrypted**, **KmsKeyArn**, and **ParentSnapshotId**, and whether your AWS account is enabled for [encryption by default \(p. 1925\)](#).

Note

- You might need additional IAM permissions to use the EBS direct APIs with encryption. For more information, see [Permissions to use AWS KMS keys \(p. 1832\)](#).
- If Amazon EBS encryption by default is enabled on your AWS account, you can't create unencrypted snapshots.
- If Amazon EBS encryption by default is enabled on your AWS account, you cannot start a new snapshot using an unencrypted parent snapshot. You must first encrypt the parent snapshot by copying it. For more information, see [Copy an Amazon EBS snapshot \(p. 1781\)](#).

Topics

- [Encryption outcomes: Unencrypted parent snapshot \(p. 1843\)](#)
- [Encryption outcomes: Encrypted parent snapshot \(p. 1844\)](#)
- [Encryption outcomes: No parent snapshot \(p. 1844\)](#)

Encryption outcomes: Unencrypted parent snapshot

The following table describes the encryption outcome for each possible combination of settings when specifying an unencrypted parent snapshot.

ParentSnapshot	Encrypted	KmsKeyArn	Encryption by default	Result
Unencrypted	Omitted	Omitted	Enabled	The request fails with ValidationException.
			Disabled	The snapshot is unencrypted.
	Specified	Enabled	Enabled	
			Disabled	
Unencrypted	True	Omitted	Enabled	The request fails with ValidationException.
			Disabled	
		Specified	Enabled	
			Disabled	
Unencrypted	False	Omitted	Enabled	The request fails with ValidationException.
			Disabled	

ParentSnapshot	Encrypted	KmsKeyArn	Encryption by default	Result
		Specified	Enabled	
			Disabled	

Encryption outcomes: Encrypted parent snapshot

The following table describes the encryption outcome for each possible combination of settings when specifying an encrypted parent snapshot.

ParentSnapshot	Encrypted	KmsKeyArn	Encryption by default	Result	
Encrypted	Omitted	Omitted	Enabled	The snapshot is encrypted using the same KMS key as the parent snapshot.	
			Disabled		
	True	Specified	Enabled	The request fails with ValidationException.	
			Disabled		
Encrypted	False	Omitted	Enabled	The request fails with ValidationException.	
			Disabled		
		Specified	Enabled		
			Disabled		
Encrypted		Omitted	Enabled	The request fails with ValidationException.	
			Disabled		
		Specified	Enabled		
			Disabled		

Encryption outcomes: No parent snapshot

The following tables describe the encryption outcome for each possible combination of settings when not using a parent snapshot.

ParentSnapshot	Encrypted	KmsKeyArn	Encryption by default	Result
Omitted	True	Omitted	Enabled	The snapshot is encrypted using the default KMS key for your account. *
			Disabled	
	False	Omitted	Enabled	The snapshot is encrypted using the KMS key specified for KmsKeyArn .
			Disabled	

ParentSnapshot	Encrypted	KmsKeyArn	Encryption by default	Result
			Disabled	The snapshot is unencrypted.
			Enabled	The request fails with ValidationException.
			Disabled	
Omitted	Omitted	Omitted	Enabled	The snapshot is encrypted using the default KMS key for your account.*
			Disabled	The snapshot is unencrypted.
		Specified	Enabled	The snapshot is encrypted using the KMS key specified for KmsKeyArn.
			Disabled	

* This default KMS key could be a customer managed key or the default AWS managed KMS key for Amazon EBS encryption.

Use Signature Version 4 signing

Signature Version 4 is the process to add authentication information to AWS requests sent by HTTP. For security, most requests to AWS must be signed with an access key, which consists of an access key ID and secret access key. These two keys are commonly referred to as your security credentials. For information about how to obtain credentials for your account, see [AWS security credentials](#).

If you intend to manually create HTTP requests, you must learn how to sign them. When you use the AWS Command Line Interface (AWS CLI) or one of the AWS SDKs to make requests to AWS, these tools automatically sign the requests for you with the access key that you specify when you configure the tools. When you use these tools, you don't need to learn how to sign requests yourself.

For more information, see [Signing AWS API requests](#) in the *IAM User Guide*.

Use checksums

The GetSnapshotBlock action returns data that is in a block of a snapshot, and the PutSnapshotBlock action adds data to a block in a snapshot. The block data that is transmitted is not signed as part of the Signature Version 4 signing process. As a result, checksums are used to validate the integrity of the data as follows:

- When you use the GetSnapshotBlock action, the response provides a Base64-encoded SHA256 checksum for the block data using the **x-amz-Checksum** header, and the checksum algorithm using the **x-amz-Checksum-Algorithm** header. Use the returned checksum to validate the integrity of the data. If the checksum that you generate doesn't match what Amazon EBS provided, you should consider the data not valid and retry your request.
- When you use the PutSnapshotBlock action, your request must provide a Base64-encoded SHA256 checksum for the block data using the **x-amz-Checksum** header, and the checksum algorithm using the **x-amz-Checksum-Algorithm** header. The checksum that you provide is validated against a checksum generated by Amazon EBS to validate the integrity of the data. If the checksums do not correspond, the request fails.
- When you use the CompleteSnapshot action, your request can optionally provide an aggregate Base64-encoded SHA256 checksum for the complete set of data added to the snapshot. Provide the checksum using the **x-amz-Checksum** header, the checksum algorithm using the **x-amz-Checksum-Algorithm** header, and the checksum aggregation method using the **x-amz-Checksum-Aggregation-Method** header. To generate the aggregated checksum using the linear aggregation method, arrange

the checksums for each written block in ascending order of their block index, concatenate them to form a single string, and then generate the checksum on the entire string using the SHA256 algorithm.

The checksums in these actions are part of the Signature Version 4 signing process.

[Idempotency for StartSnapshot API](#)

Idempotency ensures that an API request completes only once. With an idempotent request, if the original request completes successful, the subsequent retries return the result from the original successful request and they have no additional effect.

The [StartSnapshot](#) API supports idempotency using a *client token*. A client token is a unique string that you specify when you make an API request. If you retry an API request with the same client token and the same request parameters after it has completed successfully, the result of the original request is returned. If you retry a request with the same client token, but change one or more of the request parameters, the `ConflictException` error is returned.

If you do not specify your own client token, the AWS SDKs automatically generates a client token for the request to ensure that it is idempotent.

A client token can be any string that includes up to 64 ASCII characters. You should not reuse the same client tokens for different requests.

To make an idempotent StartSnapshot request with your own client token using the API

Specify the `ClientToken` request parameter.

```
POST /snapshots HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
User-Agent: <User agent parameter>
X-Amz-Date: 20200618T040724Z
Authorization: <Authentication parameter>

{
    "VolumeSize": 8,
    "ParentSnapshot": snap-123EXAMPLE1234567,
    "ClientToken": "550e8400-e29b-41d4-a716-446655440000",
    "Timeout": 60
}
```

To make an idempotent StartSnapshot request with your own client token using the AWS CLI

Specify the `client-token` request parameter.

```
C:\> aws ebs start-snapshot --region us-east-2 --volume-size 8 --parent-snapshot
snap-123EXAMPLE1234567 --timeout 60 --client-token 550e8400-e29b-41d4-a716-446655440000
```

Error retries

The **AWS SDKs** implement automatic retry logic for requests that return error responses. You can configure the retry settings for the AWS SDKs. For more information, see your SDK's documentation.

You can configure the **AWS CLI** to automatically retry some failed requests. For more information about configuring retries for the AWS CLI, see [AWS CLI retries](#) in the *AWS Command Line Interface User Guide*.

The **AWS Query API** does not support retry logic for failed requests. If you are using HTTP or HTTPS requests, you must implement retry logic in your client application.

For more information, see [Error retries and exponential backoff in AWS](#) in the *AWS General Reference*.

The following table shows the possible API error responses. Some API errors are retryable. Your client application should always retry failed requests that receive a retryable error.

Error	Response code	Description	Thrown by	Retryable?
InternalServerException	500	The request failed due to a network or AWS server-side issue.	All APIs	Yes
ThrottlingException	400	The number of API requests has exceeded the maximum allowed API request throttling limit for the account.	All APIs	Yes
RequestThrottleException	400	The number of API requests has exceeded the maximum allowed API request throttling limit for the snapshot.	GetSnapshotBlock PutSnapshotBlock	Yes
ValidationException with message "Failed to read block data"	400	The provided data block was not readable.	PutSnapshotBlock	Yes
ValidationException with any other message	400	The request syntax is malformed, or the input does not satisfy the constraints specified by the AWS service.	All APIs	No
ResourceNotFoundException	404	The specified snapshot ID does not exist.	All APIs	No
ConflictException	409	The specified client token was previously used in a similar request that had different request parameters. For more information, see Idempotency for StartSnapshot API (p. 1846) .	StartSnapshot	No
AccessDeniedException	403	You do not have permission	All APIs	No

Error	Response code	Description	Thrown by	Retryable?
		to perform the requested operation.		
ServiceQuotaExceededException	402	The request failed because fulfilling the request would exceed one or more dependent service quotas for your account.	All APIs	No
InvalidSignatureException	403	The request authorization signature has expired. You can retry the request only after refreshing the authorization signature.	All APIs	No

Optimize performance

You can run API requests concurrently. Assuming PutSnapshotBlock latency is 100ms, then a thread can process 10 requests in one second. Furthermore, assuming your client application creates multiple threads and connections (for example, 100 connections), it can make 1000 (10 * 100) requests per second in total. This will correspond to a throughput of around 500 MB per second.

The following list contains few things to look for in your application:

- Is each thread using a separate connection? If the connections are limited on the application then multiple threads will wait for the connection to be available and you will notice lower throughput.
- Is there any wait time in the application between two put requests? This will reduce the effective throughput of a thread.
- The bandwidth limit on the instance – If bandwidth on the instance is shared by other applications, it could limit the available throughput for PutSnapshotBlock requests.

Be sure to take note of other workloads that might be running in the account to avoid bottlenecks. You should also build retry mechanisms into your EBS direct APIs workflows to handle throttling, timeouts, and service unavailability.

Review the EBS direct APIs service quotas to determine the maximum API requests that you can run per second. For more information, see [Amazon Elastic Block Store Endpoints and Quotas](#) in the [AWS General Reference](#).

EBS direct APIs service endpoints

An *endpoint* is a URL that serves as an entry point for an AWS web service. EBS direct APIs supports the following endpoint types:

- IPv4 endpoints
- Dual-stack endpoints that support both IPv4 and IPv6
- FIPS endpoints

When you make a request, you can specify the endpoint and Region to use. If you do not specify an endpoint, the IPv4 endpoint is used by default. To use a different endpoint type, you must specify it in your request. For examples of how to do this, see [Specifying endpoints \(p. 1850\)](#).

For more information about Regions, see [Regions and Availability Zones](#) in the *Amazon EC2 User Guide for Linux Instances*. For a list of endpoints for EBS direct APIs, see [Endpoints for the EBS direct APIs](#) in the *Amazon Web Services General Reference*.

Topics

- [IPv4 endpoints \(p. 1849\)](#)
- [Dual-stack \(IPv4 and IPv6\) endpoints \(p. 1849\)](#)
- [FIPS endpoints \(p. 1850\)](#)
- [Specifying endpoints \(p. 1850\)](#)

IPv4 endpoints

IPv4 endpoints support IPv4 traffic only. IPv4 endpoints are available for all Regions.

If you specify the general endpoint, `ebs.amazonaws.com`, we use the endpoint for `us-east-1`. To use a different Region, specify its associated endpoint. For example, if you specify `ebs.us-east-2.amazonaws.com` as the endpoint, we direct your request to the `us-east-2` endpoint.

IPv4 endpoint names use the following naming convention:

- `ebs.region.amazonaws.com`

For example, the IPv4 endpoint name for the `us-west-1` Region is `ebs.us-west-1.amazonaws.com`. For a list of endpoints for EBS direct APIs, see [Endpoints for the EBS direct APIs](#) in the *Amazon Web Services General Reference*.

Pricing

You are not charged for data transferred directly between EBS direct APIs and Amazon EC2 instances using an IPv4 endpoint in the same Region. However, if there are intermediate services, such as AWS PrivateLink endpoints, NAT Gateway, or Amazon VPC Transit Gateways, you are charged their associated costs.

Dual-stack (IPv4 and IPv6) endpoints

Dual-stack endpoints support both IPv4 and IPv6 traffic. Dual-stack endpoints are available for all Regions.

To use IPv6, you must use a dual-stack endpoint. When you make a request to a dual-stack endpoint, the endpoint URL resolves to an IPv6 or an IPv4 address, depending on the protocol used by your network and client.

EBS direct APIs supports only regional dual-stack endpoints, which means that you must specify the Region as part of the endpoint name. Dual-stack endpoint names use the following naming convention:

- `ebs.region.api.aws`

For example, the dual-stack endpoint name for the `eu-west-1` Region is `ebs.eu-west-1.api.aws`. For a list of endpoints for EBS direct APIs, see [Endpoints for the EBS direct APIs](#) in the *Amazon Web Services General Reference*.

Pricing

You are not charged for data transferred directly between EBS direct APIs and Amazon EC2 instances using a dual-stack endpoint in the same Region. However, if there are intermediate services, such as AWS PrivateLink endpoints, NAT Gateway, or Amazon VPC Transit Gateways, you are charged their associated costs.

FIPS endpoints

EBS direct APIs provides FIPS-validated IPv4 and dual-stack (IPv4 and IPv6) endpoints for the following Regions:

- us-east-1 — US East (N. Virginia)
- us-east-2 — US East (Ohio)
- us-west-1 — US West (N. California)
- us-west-2 — US West (Oregon)
- ca-central-1 — Canada (Central)

FIPS IPv4 endpoints use the following naming convention: ebs-fips.*region*.amazonaws.com. For example, the FIPS IPv4 endpoint for us-east-1 is ebs-fips.us-east-1.amazonaws.com.

FIPS dual-stack endpoints use the following naming convention: ebs-fips.*region*.api.aws. For example, the FIPS dual-stack endpoint for us-east-1 is ebs-fips.us-east-1.api.aws.

For more information about FIPS endpoints see, [FIPS endpoints](#) in the *Amazon Web Services General Reference*.

Specifying endpoints

This section provides some examples of how to specify an endpoint when making a request.

AWS CLI

The following examples show how to specify an endpoint for the us-east-2 Region using the AWS CLI.

- **Dual-stack**

```
aws ebs list-snapshot-blocks --snapshot-id snap-0987654321 --starting-block-index
1000 --endpoint-url https://ebs.us-east-2.api.aws
```

- **IPv4**

```
aws ebs list-snapshot-blocks --snapshot-id snap-0987654321 --starting-block-index
1000 --endpoint-url https://ebs.us-east-2.amazonaws.com
```

AWS SDK for Java 2.x

The following examples show how to specify an endpoint for the us-east-2 Region using the AWS SDK for Java 2.x.

- **Dual-stack**

```
AwsClientBuilder.EndpointConfiguration config = new
AwsClientBuilder.EndpointConfiguration("https://ebs.us-east-2.api.aws", "us-
east-2");
AmazonEBS ebs = AmazonEBSClientBuilder.standard()
.withEndpointConfiguration(config)
.build();
```

- **IPv4**

```
AwsClientBuilder.EndpointConfiguration config = new
    AwsClientBuilder.EndpointConfiguration("https://ebs.us-east-2.amazonaws.com", "us-
east-2");
AmazonEBS ebs = AmazonEBSSClientBuilder.standard()
    .withEndpointConfiguration(config)
    .build();
```

AWS SDK for Go

The following examples show how to specify an endpoint for the us-east-2 Region using the AWS SDK for Go.

- **Dual-stack**

```
sess := session.Must(session.NewSession())
svc := ebs.New(sess, &aws.Config{
    Region: aws.String(endpoints.UsEast1RegionID),
    Endpoint: aws.String("https://ebs.us-east-2.api.aws")
})
```

- **IPv4**

```
sess := session.Must(session.NewSession())
svc := ebs.New(sess, &aws.Config{
    Region: aws.String(endpoints.UsEast1RegionID),
    Endpoint: aws.String("https://ebs.us-east-2.amazonaws.com")
})
```

Pricing for EBS direct APIs

Topics

- [Pricing for APIs \(p. 1851\)](#)
- [Networking costs \(p. 1851\)](#)

Pricing for APIs

The price that you pay to use the EBS direct APIs depends on the requests you make. For more information, see [Amazon EBS pricing](#).

- **ListChangedBlocks** and **ListSnapshotBlocks** APIs are charged per request. For example, if you make 100,000 **ListSnapshotBlocks** API requests in a Region that charges \$0.0006 per 1,000 requests, you will be charged \$0.06 (\$0.0006 per 1,000 requests x 100).
- **GetSnapshotBlock** is charged per block returned. For example, if you make 100,000 **GetSnapshotBlock** API requests in a Region that charges \$0.003 per 1,000 blocks returned, you will be charged \$0.30 (\$0.003 per 1,000 blocks retruned x 100).
- **PutSnapshotBlock** is charged per block written. For example, if you make 100,000 **PutSnapshotBlock** API requests in a Region that charges \$0.006 per 1,000 blocks written, you will be charged \$0.60 (\$0.006 per 1,000 blocks written x 100).

Networking costs

Data transfer costs

Data transferred directly between EBS direct APIs and Amazon EC2 instances in the same AWS Region is free when using [non-FIPS endpoints](#). For more information, see [AWS service endpoints](#). If other AWS services are in the path of your data transfer, you will be charged their associated data processing costs. These services include, but are not limited to, PrivateLink endpoints, NAT Gateway and Transit Gateway.

VPC interface endpoints

If you are using EBS direct APIs from Amazon EC2 instances or AWS Lambda functions in private subnets, you can use VPC interface endpoints, instead of using NAT gateways, to reduce network data transfer costs. For more information, see [Using interface VPC endpoints with EBS direct APIs \(p. 1852\)](#).

Using interface VPC endpoints with EBS direct APIs

You can establish a private connection between your VPC and EBS direct APIs by creating an *interface VPC endpoint*, powered by [AWS PrivateLink](#). You can access EBS direct APIs as if it were in your VPC, without using an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC don't need public IP addresses to communicate with EBS direct APIs.

We create an endpoint network interface in each subnet that you enable for the interface endpoint.

For more information, see [Access AWS services through AWS PrivateLink](#) in the *AWS PrivateLink Guide*.

Considerations for EBS direct APIs VPC endpoints

Before you set up an interface VPC endpoint for EBS direct APIs, review [Considerations](#) in the *AWS PrivateLink Guide*.

VPC endpoint policies are not supported for EBS direct APIs. By default, full access to EBS direct APIs is allowed through the endpoint. However, you can control access to the interface endpoint using security groups.

Create an interface VPC endpoint for EBS direct APIs

You can create a VPC endpoint for EBS direct APIs using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see [Create a VPC endpoint](#) in the *AWS PrivateLink Guide*.

Create a VPC endpoint for EBS direct APIs using the following service name:

- com.amazonaws.*region*.ebs

If you enable private DNS for the endpoint, you can make API requests to EBS direct APIs using its default DNS name for the Region, for example, ebs.us-east-1.amazonaws.com.

Log API Calls for EBS direct APIs with AWS CloudTrail

The EBS direct APIs service is integrated with AWS CloudTrail. CloudTrail is a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls performed in EBS direct APIs as events. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon Simple Storage Service (Amazon S3) bucket. If you don't configure a trail, you can still view the most recent management events in the CloudTrail console in **Event history**. Data events are not captured in Event history. You can use the information collected by CloudTrail to determine the request that was made to EBS direct APIs, the IP address from which the request was made, who made the request, when it was made, and additional details.

For more information about CloudTrail, see the [AWS CloudTrail User Guide](#).

EBS direct APIs Information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in EBS direct APIs, that activity is recorded in a CloudTrail event along with other AWS service

events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#).

For an ongoing record of events in your AWS account, including events for EBS direct APIs, create a trail. A *trail* enables CloudTrail to deliver log files to an S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- [Overview for Creating a Trail](#)
- [CloudTrail Supported Services and Integrations](#)
- [Configuring Amazon SNS Notifications for CloudTrail](#)
- [Receiving CloudTrail Log Files from Multiple Regions](#) and [Receiving CloudTrail Log Files from Multiple Accounts](#)

Supported API actions

For EBS direct APIs, you can use CloudTrail to log two types of events:

- **Management events** — Management events provide visibility into management operations that are performed on snapshots in your AWS account. The following API actions are logged by default as management events in trails:

- [StartSnapshot](#)
- [CompleteSnapshot](#)

For more information about logging management events, see [Logging management events for trails](#) in the *CloudTrail User Guide*.

- **Data events** — These events provide visibility into the snapshot operations performed on or within a snapshot. The following API actions can optionally be logged as data events in trails:

- [ListSnapshotBlocks](#)
- [ListChangedBlocks](#)
- [GetSnapshotBlock](#)
- [PutSnapshotBlock](#)

Data events are not logged by default when you create a trail. You can use only *advanced event selectors* to record data events on EBS direct API calls. For more information, see [Logging data events for trails](#) in the *CloudTrail User Guide*.

Note

If you perform an action on a snapshot that is shared with you, data events are not sent to the AWS account that owns the snapshot.

Identity information

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentityElement](#).

Understand EBS direct APIs Log File Entries

A trail is a configuration that enables delivery of events as log files to an S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following are example CloudTrail log entries.

StartSnapshot

```
{  
    "eventVersion": "1.05",

```

Frequently asked questions

Can a snapshot be accessed using the EBS direct APIs if it has a pending status?

No. The snapshot can be accessed only if it has a completed status.

Are the block indexes returned by the EBS direct APIs in numerical order?

Yes. The block indexes returned are unique, and in numerical order.

Can I submit a request with a MaxResults parameter value of under 100?

No. The minimum MaxResult parameter value you can use is 100. If you submit a request with a MaxResult parameter value of under 100, and there are more than 100 blocks in the snapshot, then the API will return at least 100 results.

Can I run API requests concurrently?

You can run API requests concurrently. Be sure to take note of other workloads that might be running in the account to avoid bottlenecks. You should also build retry mechanisms into your EBS direct APIs workflows to handle throttling, timeouts, and service unavailability. For more information, see [Optimize performance \(p. 1848\)](#).

Review the EBS direct APIs service quotas to determine the API requests that you can run per second. For more information, see [Amazon Elastic Block Store Endpoints and Quotas](#) in the AWS General Reference.

When running the ListChangedBlocks action, is it possible to get an empty response even though there are blocks in the snapshot?

Yes. If the changed blocks are scarce in the snapshot, the response may be empty but the API will return a next page token value. Use the next page token value to continue to the next page of results. You can confirm that you have reached the last page of results when the API returns a next page token value of null.

If the NextToken parameter is specified together with a StartingBlockIndex parameter, which of the two is used?

The NextToken is used, and the StartingBlockIndex is ignored.

How long are the block tokens and next tokens valid?

Block tokens are valid for seven days, and next tokens are valid for 60 minutes.

Are encrypted snapshots supported?

Yes. Encrypted snapshots can be accessed using the EBS direct APIs.

To access an encrypted snapshot, the user must have access to the KMS key used to encrypt the snapshot, and the AWS KMS decrypt action. See the [IAM permissions for EBS direct APIs \(p. 1829\)](#) section earlier in this guide for the AWS KMS policy to assign to a user.

Are public snapshots supported?

Public snapshots are not supported.

Are Amazon EBS local snapshots on Outposts supported?

Amazon EBS local snapshots on Outposts are not supported.

Does list snapshot block return all block indexes and block tokens in a snapshot, or only those that have data written to them?

It returns only block indexes and tokens that have data written to them.

Can I get a history of the API calls made by the EBS direct APIs on my account for security analysis and operational troubleshooting purposes?

Yes. To receive a history of EBS direct APIs API calls made on your account, turn on AWS CloudTrail in the AWS Management Console. For more information, see [Log API Calls for EBS direct APIs with AWS CloudTrail \(p. 1852\)](#).

Automate the snapshot lifecycle

You can use Amazon Data Lifecycle Manager to automate the creation, retention, and deletion of snapshots that you use to back up your Amazon EBS volumes.

For more information, see [Amazon Data Lifecycle Manager \(p. 1859\)](#).

Amazon Data Lifecycle Manager

You can use Amazon Data Lifecycle Manager to automate the creation, retention, and deletion of EBS snapshots and EBS-backed AMIs. When you automate snapshot and AMI management, it helps you to:

- Protect valuable data by enforcing a regular backup schedule.
- Create standardized AMIs that can be refreshed at regular intervals.
- Retain backups as required by auditors or internal compliance.
- Reduce storage costs by deleting outdated backups.
- Create disaster recovery backup policies that back up data to isolated accounts.

When combined with the monitoring features of Amazon CloudWatch Events and AWS CloudTrail, Amazon Data Lifecycle Manager provides a complete backup solution for Amazon EC2 instances and individual EBS volumes at no additional cost.

Important

Amazon Data Lifecycle Manager cannot be used to manage snapshots or AMIs that are created by any other means.

Amazon Data Lifecycle Manager cannot be used to automate the creation, retention, and deletion of instance store-backed AMIs.

How Amazon Data Lifecycle Manager works

The following are the key elements of Amazon Data Lifecycle Manager.

Elements

- [Snapshots \(p. 1860\)](#)
- [EBS-backed AMIs \(p. 1860\)](#)
- [Target resource tags \(p. 1860\)](#)
- [Amazon Data Lifecycle Manager tags \(p. 1860\)](#)
- [Lifecycle policies \(p. 1861\)](#)
- [Policy schedules \(p. 1861\)](#)

Snapshots

Snapshots are the primary means to back up data from your EBS volumes. To save storage costs, successive snapshots are incremental, containing only the volume data that changed since the previous snapshot. When you delete one snapshot in a series of snapshots for a volume, only the data that's unique to that snapshot is removed. The rest of the captured history of the volume is preserved. For more information, see [Amazon EBS snapshots \(p. 1757\)](#).

EBS-backed AMIs

An Amazon Machine Image (AMI) provides the information that's required to launch an instance. You can launch multiple instances from a single AMI when you need multiple instances with the same configuration. Amazon Data Lifecycle Manager supports EBS-backed AMIs only. EBS-backed AMIs include a snapshot for each EBS volume that's attached to the source instance. For more information, see [Amazon Machine Images \(AMI\) \(p. 28\)](#).

Target resource tags

Amazon Data Lifecycle Manager uses resource tags to identify the resources to back up. When you create a snapshot or EBS-backed AMI policy, you can specify multiple target resource tags. All resources of the specified type (instance or volume) that have at least one of the specified target resource tags will be targeted by the policy. For example, if you create a snapshot policy that targets volumes and you specify purpose=prod, costcenter=prod, and environment=live as target resource tags, then the policy will target all volumes that have any of those tag-key value pairs.

If you want to run multiple policies on a resource, you can assign multiple tags to the target resource, and then create separate policies that each target a specific resource tag.

You can't use the \ or = characters in a tag key. Target resource tags are case sensitive. For more information, see [Tag your Amazon EC2 resources \(p. 2085\)](#).

Amazon Data Lifecycle Manager tags

Amazon Data Lifecycle Manager applies the following system tags to all snapshots and AMIs created by a policy, to distinguish them from snapshots and AMIs created by any other means:

- aws:dlm:lifecycle-policy-id
- aws:dlm:lifecycle-schedule-name
- aws:dlm:expirationTime — For snapshots created by an age-based schedule. Indicates when the snapshot is to be deleted from the standard tier.
- dlm:managed
- aws:dlm:archived — For snapshots that were archived by a schedule.

You can also specify custom tags to be applied to snapshots and AMIs on creation. You can't use the \ or = characters in a tag key.

The target tags that Amazon Data Lifecycle Manager uses to associate volumes with a snapshot policy can optionally be applied to snapshots created by the policy. Similarly, the target tags that are used to associate instances with an AMI policy can optionally be applied to AMIs created by the policy.

Lifecycle policies

A lifecycle policy consists of these core settings:

- **Policy type**—Defines the type of resources that the policy can manage. Amazon Data Lifecycle Manager supports the following types of lifecycle policies:
 - Snapshot lifecycle policy—Used to automate the lifecycle of EBS snapshots. These policies can target individual EBS volumes or all EBS volumes attached to an instance.
 - EBS-backed AMI lifecycle policy—Used to automate the lifecycle of EBS-backed AMIs and their backing snapshots. These policies can target instances only.
 - Cross-account copy event policy—Used to automate snapshot copies across accounts. Use this policy type in conjunction with an EBS snapshot policy that shares snapshots across accounts.
- **Resource type**—Defines the type of resources that are targeted by the policy. Snapshot lifecycle policies can target instances or volumes. Use VOLUME to create snapshots of individual volumes, or use INSTANCE to create multi-volume snapshots of all of the volumes that are attached to an instance. For more information, see [Multi-volume snapshots \(p. 1763\)](#). AMI lifecycle policies can target instances only. One AMI is created that includes snapshots of all of the volumes that are attached to the target instance.
- **Target tags**—Specifies the tags that must be assigned to an EBS volume or an Amazon EC2 instance for it to be targeted by the policy.
- **Policy schedules**(Snapshot and AMI policies only)—Define when snapshots or AMIs are to be created and how long to retain them for. For more information, see [Policy schedules \(p. 1861\)](#).

For example, you could create a policy with settings similar to the following:

- Manages all EBS volumes that have a tag with a key of account and a value of finance.
- Creates snapshots every 24 hours at 0900 UTC.
- Retains only the five most recent snapshots.
- Starts snapshot creation no later than 0959 UTC each day.

Policy schedules

Policy schedules define when snapshots or AMIs are created by the policy. Policies can have up to four schedules—one mandatory schedule, and up to three optional schedules.

Adding multiple schedules to a single policy lets you create snapshots or AMIs at different frequencies using the same policy. For example, you can create a single policy that creates daily, weekly, monthly, and yearly snapshots. This eliminates the need to manage multiple policies.

For each schedule, you can define the frequency, fast snapshot restore settings (snapshot lifecycle policies only), cross-Region copy rules, and tags. The tags that are assigned to a schedule are automatically assigned to the snapshots or AMIs that are created when the schedule is initiated. In addition, Amazon Data Lifecycle Manager automatically assigns a system-generated tag based on the schedule's frequency to each snapshot or AMI.

Each schedule is initiated individually based on its frequency. If multiple schedules are initiated at the same time, Amazon Data Lifecycle Manager creates only one snapshot or AMI and applies the retention

settings of the schedule that has the highest retention period. The tags of all of the initiated schedules are applied to the snapshot or AMI.

- (Snapshot lifecycle policies only) If more than one of the initiated schedules is enabled for fast snapshot restore, then the snapshot is enabled for fast snapshot restore in all of the Availability Zones specified across all of the initiated schedules. The highest retention settings of the initiated schedules is used for each Availability Zone.
- If more than one of the initiated schedules is enabled for cross-Region copy, the snapshot or AMI is copied to all Regions specified across all of the initiated schedules. The highest retention period of the initiated schedules is applied.

Quotas

Your AWS account has the following quotas related to Amazon Data Lifecycle Manager:

Description	Quota
Lifecycle policies per Region	100
Tags per resource	45

Automate snapshot lifecycles

The following procedure shows you how to use Amazon Data Lifecycle Manager to automate Amazon EBS snapshot lifecycles.

Topics

- [Create a snapshot lifecycle policy \(p. 1862\)](#)
- [Considerations for snapshot lifecycle policies \(p. 1871\)](#)
- [Additional resources \(p. 1875\)](#)

Create a snapshot lifecycle policy

Use one of the following procedures to create a snapshot lifecycle policy.

Console

To create a snapshot policy

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Elastic Block Store, Lifecycle Manager**, and then choose **Create lifecycle policy**.
3. On the **Select policy type** screen, choose **EBS snapshot policy** and then choose **Next**.
4. In the **Target resources** section, do the following:
 - a. For **Target resource types**, choose the type of resource to back up. Choose **Volume** to create snapshots of individual volumes, or choose **Instance** to create multi-volume snapshots from the volumes attached to an instance.
 - b. (For AWS Outpost customers only) For **Target resource location**, specify where the target resources are located.
 - If the target resources are located in an AWS Region, choose **AWS Region**. Amazon Data Lifecycle Manager backs up all resources of the specified type that have matching target

tags in the current Region only. If the resource is located in a Region, snapshots created by the policy will be stored in the same Region.

- If the target resources are located on an Outpost in your account, choose **AWS Outpost**. Amazon Data Lifecycle Manager backs up all resources of the specified type that have matching target tags across all of the Outposts in your account. If the resource is located on an Outpost, snapshots created by the policy can be stored in the same Region or on the same Outpost as the resource.
 - If you do not have any Outposts in your account, this option is hidden and AWS Region is selected for you.
- c. For **Target resource tags**, choose the resource tags that identify the volumes or instances to back up. Only resources that have the specified tag key and value pairs are backed up by the policy.
 5. For **Description**, enter a brief description for the policy.
 6. For **IAM role**, choose the IAM role that has permissions to manage snapshots and to describe volumes and instances. To use the default role provided by Amazon Data Lifecycle Manager, choose **Default role**. Alternatively, to use a custom IAM role that you previously created, choose **Choose another role** and then select the role to use.
 7. For **Policy tags**, add the tags to apply to the lifecycle policy. You can use these tags to identify and categorize your policies.
 8. For **Policy status**, choose **Enable** to start the policy runs at the next scheduled time, or **Disable policy** to prevent the policy from running. If you do not enable the policy now, it will not start creating snapshots until you manually enable it after creation.
 9. (Only for policies that target instances) By default, Amazon Data Lifecycle Manager will create snapshots of all the volumes attached to targeted instances. However, you can choose to create snapshots of a subset of the attached volumes. In the **Parameters** section, do the following:
 - If you do not want to create snapshots of the root volumes attached to the targeted instances, select **Exclude root volume**. If you select this option, only the data (non-root) volumes that are attached to targeted instances will be included in the multi-volume snapshot sets.
 - If you want to create snapshots of a subset of the data (non-root) volumes attached to the targeted instances, select **Exclude specific data volumes**, and then specify the tags that are to be used to identify the data volumes that should not be snapshotted. Amazon Data Lifecycle Manager will not create snapshots of data volumes that have any of the specified tags. Amazon Data Lifecycle Manager will create snapshots only of data volumes that do not have any of the specified tags.
10. Choose **Next**.
11. On the **Configure schedule** screen, configure the policy schedules. A policy can have up to 4 schedules. Schedule 1 is mandatory. Schedules 2, 3, and 4 are optional. For each policy schedule that you add, do the following:
- a. In the **Schedule details** section do the following:
 - i. For **Schedule name**, specify a descriptive name for the schedule.
 - ii. For **Frequency** and the related fields, configure the interval between policy runs. You can configure policy runs on a daily, weekly, monthly, or yearly schedule. Alternatively, choose **Custom cron expression** to specify an interval of up to one year. For more information, see [Cron expressions](#) in the *Amazon CloudWatch Events User Guide*.

Note

If you need to enable **snapshot archiving** for the schedule, then you must select either the **monthly** or **yearly** frequency, or you must specify a cron expression with a creation frequency of at least 28 days.

If specify a monthly frequency that creates snapshots on a specific day in a specific week (for example, the second Thursday of the month), then for

- count-based schedule, the retention count for the archive tier must be 4 or more.
- iii. For **Starting at**, specify the time at which the policy runs are scheduled to start. The first policy run starts within an hour after the scheduled time. The time must be entered in the hh:mm UTC format.
 - iv. For **Retention type**, specify the retention policy for snapshots created by the schedule. You can retain snapshots based on either their total count or their age.
 - (Count-based retention) If you do not enable snapshot archiving, the range is 1 to 1000. If you enable snapshot archiving, the range is 0 to 1000. If you specify a count of 0, snapshots are archived immediately after creation.
 - (Age-based retention) If you do not enable snapshot archiving, the range is 1 day to 100 years. If you enable snapshot archiving, the range is 0 days to 100 years. If you specify 0 days, snapshots are archived immediately after creation.

Note

- All schedules must have the same retention type (age-based or count-based). You can specify the retention type for Schedule 1 only. Schedules 2, 3, and 4 inherit the retention type from Schedule 1. Each schedule can have its own retention count or period.
 - If you enable fast snapshot restore, cross-Region copy, or snapshot sharing, then you must specify a retention count of 1 or more, or a retention period of 1 day or longer.
 - If you enable snapshot archiving, this retention rule determines how long the snapshot remains in the standard tier before being archived. Once the standard tier retention threshold is met, the snapshot is converted to a full snapshot and it is moved to the archive tier.
- v. (For AWS Outposts customers only) For **Snapshot destination**, specify the destination for snapshots created by the policy.
 - If the policy targets resources in a Region, snapshots must be created in the same Region. AWS Region is selected for you.
 - If the policy targets resources on an Outpost, you can choose to create snapshots on the same Outpost as the source resource, or in the Region that is associated with the Outpost.
 - If you do not have any Outposts in your account, this option is hidden and AWS Region is selected for you.
- b. In the **Tagging** section, do the following:
 - i. To copy all of the user-defined tags from the source volume to the snapshots created by the schedule, select **Copy tags from source**.
 - ii. To specify additional tags to assign to snapshots created by this schedule, choose **Add tags**.
 - c. (Only for policies that target volumes) In the **Snapshot archiving** section, do the following:

Note

You can enable snapshot archiving for only one schedule in a policy.

- i. To enable snapshot archiving for the schedule, select **Archive snapshots created by this schedule**.

Note

You can enable snapshot archiving only if the snapshot creation frequency is monthly or yearly, or if you specify a cron expression with a creation frequency of at least 28 days.

- ii. Specify the retention rule for snapshots in the archive tier.

- For **count-based schedules**, specify the number of snapshots to retain in the archive tier. When the retention threshold is reached, the oldest snapshot is permanently deleted from the archive tier. For example, if you specify 3, the schedule will retain a maximum of 3 snapshots in the archive tier. When the fourth snapshot is archived, the oldest of the three existing snapshots in the archive tier is deleted.
- For **age-based schedules**, specify the time period for which to retain snapshots in the archive tier. When the retention threshold is reached, the oldest snapshot is permanently deleted from the archive tier. For example, if you specify 120 days, the schedule will automatically delete snapshots from the archive tier when they reach that age.

Important

The minimum retention period for archived snapshots is 90 days. You must specify a retention rule that retains the snapshot for at least 90 days.

- d. To enable fast snapshot restore for snapshots created by the schedule, in the **Fast snapshot restore** section, select **Enable fast snapshot restore**. If you enable fast snapshot restore, you must choose the Availability Zones in which to enable it. If the schedule uses an age-based retention schedule, you must specify the period for which to enable fast snapshot restore for each snapshot. If the schedule uses count-based retention, you must specify the maximum number of snapshots to enable for fast snapshot restore.

If the schedule creates snapshots on an Outpost, you can't enable fast snapshot restore. Fast snapshot restore is not supported with local snapshots that are stored on an Outpost.

Note

You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour.

- e. To copy snapshots created by the schedule to an Outpost or to a different Region, in the **Cross-Region copy** section, select **Enable cross-Region copy**.

If the schedule creates snapshots in a Region, you can copy the snapshots to up to three additional Regions or Outposts in your account. You must specify a separate cross-Region copy rule for each destination Region or Outpost.

For each Region or Outpost, you can choose different retention policies and you can choose whether to copy all tags or no tags. If the source snapshot is encrypted, or if encryption by default is enabled, the copied snapshots are encrypted. If the source snapshot is unencrypted, you can enable encryption. If you do not specify a KMS key, the snapshots are encrypted using the default KMS key for EBS encryption in each destination Region. If you specify a KMS key for the destination Region, then the selected IAM role must have access to the KMS key.

Note

You must ensure that you do not exceed the number of concurrent snapshot copies per Region.

If the policy creates snapshots on an Outpost, then you can't copy the snapshots to a Region or to another Outpost and the cross-Region copy settings are not available.

- f. In the **Cross-account sharing**, configure the policy to automatically share the snapshots created by the schedule with other AWS accounts. Do the following:
 - i. To enable sharing with other AWS accounts, select **Enable cross-account sharing**.
 - ii. To add the accounts with which to share the snapshots, choose **Add account**, enter the 12-digit AWS account ID, and choose **Add**.
 - iii. To automatically unshare shared snapshots after a specific period, select **Unshare automatically**. If you choose to automatically unshare shared snapshots, the period after which to automatically unshare the snapshots cannot be longer than the period for which the policy retains its snapshots. For example, if the policy's retention configuration retains snapshots for a period of 5 days, you can configure the policy to automatically unshare shared snapshots after periods up to 4 days. This applies to policies with age-based and count-based snapshot retention configurations.

If you do not enable automatic unsharing, the snapshot is shared until it is deleted.

Note

You can only share snapshots that are unencrypted or that are encrypted using a customer managed key. You can't share snapshots that are encrypted with the default EBS encryption KMS key. If you share encrypted snapshots, then you must also share the KMS key that was used to encrypt the source volume with the target accounts. For more information, see [Allowing users in other accounts to use a KMS key](#) in the *AWS Key Management Service Developer Guide*.

 - g. To add additional schedules, choose **Add another schedule**, which is located at the top of the screen. For each additional schedule, complete the fields as described previously in this topic.
 - h. After you have added the required schedules, choose **Review policy**.
12. Review the policy summary, and then choose **Create policy**.

Command line

Use the [create-lifecycle-policy](#) command to create a snapshot lifecycle policy. For PolicyType, specify EBS_SNAPSHOT_MANAGEMENT.

Note

To simplify the syntax, the following examples use a JSON file, policyDetails.json, that includes the policy details.

Example 1—Snapshot lifecycle policy with two schedules

This example creates a snapshot lifecycle policy that creates snapshots of all volumes that have a tag key of costcenter with a value of 115. The policy includes two schedules. The first schedule creates a snapshot every day at 03:00 UTC. The second schedule creates a weekly snapshot every Friday at 17:00 UTC.

```
aws dlm create-lifecycle-policy \
--description "My volume policy" \
--state ENABLED \
--execution-role-arn
arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
--policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```
{  
    "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",  
    "ResourceTypes": [
```

```
"VOLUME"
],
"TargetTags": [{"Key": "costcenter", "Value": "115"}],
"Schedules": [{"Name": "DailySnapshots", "TagsToAdd": [{"Key": "type", "Value": "myDailySnapshot"}]}, {"CreateRule": {"Interval": 24, "IntervalUnit": "HOURS", "Times": ["03:00"]}}, {"RetainRule": {"Count": 5}}], "CopyTags": false},
{
  "Name": "WeeklySnapshots", "TagsToAdd": [{"Key": "type", "Value": "myWeeklySnapshot"}]}, {"CreateRule": {"CronExpression": "cron(0 17 ? * FRI *)"}}, {"RetainRule": {"Count": 5}}], "CopyTags": false}
]}
]
```

If the request succeeds, the command returns the ID of the newly created policy. The following is example output.

```
{
  "PolicyId": "policy-0123456789abcdef0"
}
```

Example 2—Snapshot lifecycle policy that targets instances and creates snapshots of a subset of data (non-root) volumes

This example creates a snapshot lifecycle policy that creates multi-volume snapshot sets from instances tagged with `code=production`. The policy includes only one schedule. The schedule does not create snapshots of the data volumes that are tagged with `code=temp`.

```
aws dlm create-lifecycle-policy \
--description "My volume policy" \
--state ENABLED \
--execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
--policy-details file://policyDetails.json
```

The following is an example of the `policyDetails.json` file.

```
{  
    "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",  
    "ResourceTypes": [  
        "INSTANCE"  
    ],  
    "TargetTags": [{  
        "Key": "code",  
        "Value": "production"  
    }],  
    "Parameters": {  
        "ExcludeDataVolumeTags": [{  
            "Key": "code",  
            "Value": "temp"  
        }]  
    },  
    "Schedules": [{  
        "Name": "DailySnapshots",  
        "TagsToAdd": [{  
            "Key": "type",  
            "Value": "myDailySnapshot"  
        }],  
        "CreateRule": {  
            "Interval": 24,  
            "IntervalUnit": "HOURS",  
            "Times": [  
                "03:00"  
            ]  
        },  
        "RetainRule": {  
            "Count": 5  
        },  
        "CopyTags": false  
    }]  
}
```

If the request succeeds, the command returns the ID of the newly created policy. The following is example output.

```
{  
    "PolicyId": "policy-0123456789abcdef0"  
}
```

Example 3—Snapshot lifecycle policy that automates local snapshots of Outpost resources

This example creates a snapshot lifecycle policy that creates snapshots of volumes tagged with `team=dev` across all of your Outposts. The policy creates the snapshots on the same Outposts as the source volumes. The policy creates snapshots every 12 hours starting at `00:00` UTC.

```
aws dlm create-lifecycle-policy \  
    --description "My local snapshot policy" \  
    --state ENABLED \  
    --execution-role-arn  
    arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \  
    --policy-details file://policyDetails.json
```

The following is an example of the `policyDetails.json` file.

```
{  
    "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",  
    "ResourceTypes": "VOLUME",  
    "ResourceLocations": "OUTPOST",
```

```
"TargetTags": [{"Key": "team", "Value": "dev"}],  
"Schedules": [{"Name": "on-site backup", "CreateRule": {"Interval": 12, "IntervalUnit": "HOURS", "Times": ["00:00"]}, "Location": ["OUTPOST_LOCAL"]}, {"RetainRule": {"Count": 1}}, {"CopyTags": false}],  
}]}
```

Example 4—Snapshot lifecycle policy that creates snapshots in a Region and copies them to an Outpost

The following example policy creates snapshots of volumes that are tagged with team=dev. Snapshots are created in the same Region as the source volume. Snapshots are created every 12 hours starting at 00:00 UTC, and retains a maximum of 1 snapshot. The policy also copies the snapshots to Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0, encrypts the copied snapshots using the default encryption KMS key, and retains the copies for 1 month.

```
aws dlm create-lifecycle-policy \  
--description "Copy snapshots to Outpost" \  
--state ENABLED \  
--execution-role-arn  
arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \  
--policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```
{  
    "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",  
    "ResourceTypes": "VOLUME",  
    "ResourceLocations": "CLOUD",  
    "TargetTags": [{"Key": "team", "Value": "dev"}],  
    "Schedules": [{"Name": "on-site backup", "CopyTags": false, "CreateRule": {"Interval": 12, "IntervalUnit": "HOURS", "Times": ["00:00"]}, "Location": "CLOUD"}, {"RetainRule": {}}]}
```

```
        "Count": 1
    },
    "CrossRegionCopyRules" : [
        {
            "Target": "arn:aws:outposts:us-east-1:123456789012:outpost/
op-1234567890abcdef0",
            "Encrypted": true,
            "CopyTags": true,
            "RetainRule": {
                "Interval": 1,
                "IntervalUnit": "MONTHS"
            }
        }
    ]
}
```

Example 5—Snapshot lifecycle policy with an archive-enabled, age-based schedule

This example creates a snapshot lifecycle policy that targets volumes tagged with Name=Prod. The policy has one age-based schedule that creates snapshots on the first day of each month at 09:00. The schedule retains each snapshot in the standard tier for one day, after which it moves them to the archive tier. Snapshots are stored in the archive tier for 90 days before being deleted.

```
aws dlm create-lifecycle-policy \
--description "Copy snapshots to Outpost" \
--state ENABLED \
--execution-role-arn
arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
--policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```
{
    "ResourceTypes": [ "VOLUME"],
    "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
    "Schedules" : [
        {
            "Name": "sched1",
            "TagsToAdd": [
                {"Key":"createdby","Value":"dlm"}
            ],
            "CreateRule": {
                "CronExpression": "cron(0 9 1 * ? *)"
            },
            "CopyTags": true,
            "RetainRule":{
                "Interval": 1,
                "IntervalUnit": "DAYS"
            },
            "ArchiveRule": {
                "RetainRule":{
                    "RetentionArchiveTier": {
                        "Interval": 90,
                        "IntervalUnit": "DAYS"
                    }
                }
            }
        }
    ],
    "TargetTags": [
        {
            "Key": "Name",
            "Value": "Prod"
        }
    ]
}
```

```
        ]  
    }  
}
```

Example 6—Snapshot lifecycle policy with an archive-enabled, count-based schedule

This example creates a snapshot lifecycle policy that targets volumes tagged with Purpose=Test. The policy has one count-based schedule that creates snapshots on the first day of each month at 09:00. The schedule archives snapshots immediately after creation and retains a maximum of three snapshots in the archive tier.

```
aws dlm create-lifecycle-policy \  
  --description "Copy snapshots to Outpost" \  
  --state ENABLED \  
  --execution-role-arn  
  arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \  
  --policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```
{  
    "ResourceTypes": [ "VOLUME"],  
    "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",  
    "Schedules" : [  
        {  
            "Name": "sched1",  
            "TagsToAdd": [  
                {"Key": "createdby", "Value": "dlm"}  
            ],  
            "CreateRule": {  
                "CronExpression": "cron(0 9 1 * ? *)"  
            },  
            "CopyTags": true,  
            "RetainRule":{  
                "Count": 0  
            },  
            "ArchiveRule": {  
                "RetainRule":{  
                    "RetentionArchiveTier": {  
                        "Count": 3  
                    }  
                }  
            }  
        }  
    ],  
    "TargetTags": [  
        {  
            "Key": "Purpose",  
            "Value": "Test"  
        }  
    ]  
}
```

Considerations for snapshot lifecycle policies

The following **general considerations** apply to snapshot lifecycle policies:

- Snapshot lifecycle policies target only instances or volumes that are in the same Region as the policy.
- The first snapshot creation operation starts within one hour after the specified start time. Subsequent snapshot creation operations start within one hour of their scheduled time.

- You can create multiple policies to back up a volume or instance. For example, if a volume has two tags, where tag A is the target for policy A to create a snapshot every 12 hours, and tag B is the target for policy B to create a snapshot every 24 hours, Amazon Data Lifecycle Manager creates snapshots according to the schedules for both policies. Alternatively, you can achieve the same result by creating a single policy that has multiple schedules. For example, you can create a single policy that targets only tag A, and specify two schedules — one for every 12 hours and one for every 24 hours.
- Target resource tags are case sensitive.
- If you remove the target tags from a resource that is targeted by a policy, Amazon Data Lifecycle Manager no longer manages existing snapshots in the standard tier and archive tier; you must manually delete them if they are no longer needed.
- If you create a policy that targets instances, and new volumes are attached to a target instance after the policy has been created, the newly-added volumes are included in the backup at the next policy run. All volumes attached to the instance at the time of the policy run are included.
- If you create a policy with a custom cron-based schedule that is configured to create only one snapshot, the policy will not automatically delete that snapshot when the retention threshold is reached. You must manually delete the snapshot if it is no longer needed.
- If you create an age-based policy where the retention period is shorter than the creation frequency, Amazon Data Lifecycle Manager will always retain the last snapshot until the next one is created. For example, if an age-based policy creates one snapshot every month with a retention period of seven days, Amazon Data Lifecycle Manager will retain each snapshot for one month, even though the retention period is seven days.

The following considerations apply to [snapshot archiving \(p. 1785\)](#):

- You can enable snapshot archiving only for snapshot policies that target volumes.
- You can specify an archiving rule for only one schedule for each policy.
- If you are using the console, you can enable snapshot archiving only if the schedule has a monthly or yearly creation frequency, or if the schedule has a cron expression with a creation frequency of at least 28 days.

If you are using the AWS CLI, AWS API, or AWS SDK, you can enable snapshot archiving only if the schedule has a cron expression with a creation frequency of at least 28 days.

- The minimum retention period in the archive tier is 90 days.
- When a snapshot is archived, it is converted to a full snapshot when it is moved to the archive tier. This could result in higher snapshot storage costs. For more information, see [Pricing and billing \(p. 1787\)](#).
- Fast snapshot restore and snapshot sharing are disabled for snapshots when they are archived.
- If, in the case of a leap year, your retention rule results in an archive retention period of less than 90 days, Amazon Data Lifecycle Manager ensures that snapshots are retained for the minimum 90-day period.
- If you manually archive a snapshot created by Amazon Data Lifecycle Manager, and the snapshot is still archived when the schedule's retention threshold is reached, Amazon Data Lifecycle Manager no longer manages that snapshot. However, if you restore the snapshot to the standard tier before the schedule's retention threshold is reached, the schedule will continue to manage the snapshot as per the retention rules.
- If you permanently or temporarily restore a snapshot archived by Amazon Data Lifecycle Manager to the standard tier, and the snapshot is still in the standard tier when the schedule's retention threshold is reached, Amazon Data Lifecycle Manager no longer manages the snapshot. However, if you re-archive the snapshot before the schedule's retention threshold is reached, the schedule will delete the snapshot when the retention threshold is met.
- Snapshots archived by Amazon Data Lifecycle Manager count towards your Archived snapshots per volume and In-progress snapshot archives per account quotas.
- If a schedule is unable to archive a snapshot after retrying for 24 hours, the snapshot remains in the standard tier and it is scheduled for deletion based on the time that it would have been deleted

from the archive tier. For example, if the schedule archives snapshots for 120 days, it remains in the standard tier for 120 days after the failed archiving before being permanently deleted. For count-based schedules, the snapshot does not count towards the schedule's retention count.

- Snapshots must be archived in the same Region in which they were created. If you enabled cross-Region copy and snapshot archiving, Amazon Data Lifecycle Manager does not archive the snapshot copy.
- Snapshots archived by Amazon Data Lifecycle Manager are tagged with the `aws:dlm:archived=true` system tag. Additionally, snapshots created by an archive-enabled, age-based schedule are tagged with the `aws:dlm:expirationTime` system tag, which indicates the date and time at which the snapshot is scheduled to be archived.

The following considerations apply to **excluding root volumes and data (non-root) volumes**:

- If you choose to exclude boot volumes and you specify tags that consequently exclude all of the additional data volumes attached to an instance, then Amazon Data Lifecycle Manager will not create any snapshots for the affected instance, and it will emit a `SnapshotsCreateFailed` CloudWatch metric. For more information, see [Monitor your policies using CloudWatch](#).

The following considerations apply to **deleting volumes or terminating instances targeted by snapshot lifecycle policies**:

- If you delete a volume or terminate an instance targeted by a policy with a count-based retention schedule, Amazon Data Lifecycle Manager no longer manages snapshots in the standard tier and archive tier that were created from the deleted volume or instance. You must manually delete those earlier snapshots if they are no longer needed.
- If you delete a volume or terminate an instance targeted by a policy with an age-based retention schedule, the policy continues to delete snapshots from the standard tier and archive tier that were created from the deleted volume or instance on the defined schedule, up to, but not including, the last snapshot. You must manually delete the last snapshot if it is no longer needed.

The following considerations apply to snapshot lifecycle policies and [fast snapshot restore \(p. 1934\)](#):

- Amazon Data Lifecycle Manager can enable fast snapshot restore only for snapshots with a size of 16 TiB or less. For more information, see [Amazon EBS fast snapshot restore \(p. 1934\)](#).
- A snapshot that is enabled for fast snapshot restore remains enabled even if you delete or disable the policy, disable fast snapshot restore for the policy, or disable fast snapshot restore for the Availability Zone. You must disable fast snapshot restore for these snapshots manually.
- If you enable fast snapshot restore for a policy and you exceed the maximum number of snapshots that can be enabled for fast snapshot restore, Amazon Data Lifecycle Manager creates snapshots as scheduled but does not enable them for fast snapshot restore. After a snapshot that is enabled for fast snapshot restore is deleted, the next snapshot that Amazon Data Lifecycle Manager creates is enabled for fast snapshot restore.
- When fast snapshot restore is enabled for a snapshot, it takes 60 minutes per TiB to optimize the snapshot. We recommend that you configure your schedules so that each snapshot is fully optimized before Amazon Data Lifecycle Manager creates the next snapshot.
- If you enable fast snapshot restore for a policy that targets instances, Amazon Data Lifecycle Manager enables fast snapshot restore for each snapshot in the multi-volume snapshot set individually. If Amazon Data Lifecycle Manager fails to enable fast snapshot restore for one of the snapshots in the multi-volume snapshot set, it will still attempt to enable fast snapshot restore for the remaining snapshots in the snapshot set.
- You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour. For more information, see [Pricing and Billing \(p. 1939\)](#).

Note

Depending on the configuration of your lifecycle policies, you could have multiple snapshots enabled for fast snapshot restore in multiple Availability Zones simultaneously.

The following considerations apply to **sharing snapshots across accounts**:

- You can only share snapshots that are unencrypted or that are encrypted using a customer managed key.
- You can't share snapshots that are encrypted with the default EBS encryption KMS key.
- If you share encrypted snapshots, you must also share the KMS key that was used to encrypt the source volume with the target accounts. For more information, see [Allowing users in other accounts to use a KMS key](#) in the *AWS Key Management Service Developer Guide*.

The following considerations apply to snapshots policies and [**snapshot archiving \(p. 1785\)**](#):

- If you manually archive a snapshot that was created by a policy, and that snapshot is in the archive tier when the policy's retention threshold is reached, Amazon Data Lifecycle Manager will not delete the snapshot. Amazon Data Lifecycle Manager does not manage snapshots while they are stored in the archive tier. If you no longer need snapshots that are stored in the archive tier, you must manually delete them.

The following considerations apply to snapshot policies and [**Recycle Bin \(p. 2045\)**](#):

- If Amazon Data Lifecycle Manager deletes a snapshot and sends it to the Recycle Bin when the policy's retention threshold is reached, and you manually restore the snapshot from the Recycle Bin, you must manually delete that snapshot when it is no longer needed. Amazon Data Lifecycle Manager will no longer manage the snapshot.
- If you manually delete a snapshot that was created by a policy, and that snapshot is in the Recycle Bin when the policy's retention threshold is reached, Amazon Data Lifecycle Manager will not delete the snapshot. Amazon Data Lifecycle Manager does not manage the snapshots while they are stored in the Recycle Bin.

If the snapshot is restored from the Recycle Bin before the policy's retention threshold is reached, Amazon Data Lifecycle Manager will delete the snapshot when the policy's retention threshold is reached.

If the snapshot is restored from the Recycle Bin after the policy's retention threshold is reached, Amazon Data Lifecycle Manager will no longer delete the snapshot. You must manually delete the snapshot when it is no longer needed.

The following considerations apply to snapshot lifecycle policies that are in the **error** state:

- For policies with age-based retention schedules, snapshots that are set to expire while the policy is in the **error** state are retained indefinitely. You must delete the snapshots manually. When you re-enable the policy, Amazon Data Lifecycle Manager resumes deleting snapshots as their retention periods expire.
- For policies with count-based retention schedules, the policy stops creating and deleting snapshots while it is in the **error** state. When you re-enable the policy, Amazon Data Lifecycle Manager resumes creating snapshots, and it resumes deleting snapshots as the retention threshold is met.

Additional resources

For more information, see the [Automating Amazon EBS snapshot and AMI management using Amazon Data Lifecycle Manager](#) AWS storage blog.

Automate AMI lifecycles

The following procedure shows you how to use Amazon Data Lifecycle Manager to automate EBS-backed AMI lifecycles.

Topics

- [Create an AMI lifecycle policy \(p. 1875\)](#)
- [Considerations for AMI lifecycle policies \(p. 1879\)](#)
- [Additional resources \(p. 1881\)](#)

Create an AMI lifecycle policy

Use one of the following procedures to create an AMI lifecycle policy.

Console

To create an AMI policy

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Elastic Block Store, Lifecycle Manager**, and then choose **Create lifecycle policy**.
3. On the **Select policy type** screen, choose **EBS-backed AMI policy**, and then choose **Next**.
4. In the **Target resources** section, for **Target resource tags**, choose the resource tags that identify the volumes or instances to back up. The policy backs up only the resources that have the specified tag key and value pairs.
5. For **Description**, enter a brief description for the policy.
6. For **IAM role**, choose the IAM role that has permissions to manage AMIs and snapshot and to describe instances. To use the default role provided by Amazon Data Lifecycle Manager, choose **Default role**. Alternatively, to use a custom IAM role that you previously created, choose **Choose another role**, and then select the role to use.
7. For **Policy tags**, add the tags to apply to the lifecycle policy. You can use these tags to identify and categorize your policies.
8. For **Policy status after creation**, choose **Enable policy** to start running the policy at the next scheduled time, or **Disable policy** to prevent the policy from running. If you do not enable the policy now, it will not start creating AMIs until you manually enable it after creation.
9. In the **Instance reboot** section, indicate whether instances should be rebooted before AMI creation. To prevent the targeted instances from being rebooted, choose **No**. Choosing **No** could cause data consistency issues. To reboot instances before AMI creation, choose **Yes**. Choosing this ensures data consistency, but could result in multiple targeted instances rebooting simultaneously.
10. Choose **Next**.
11. On the **Configure schedule** screen, configure the policy schedules. A policy can have up to four schedules. Schedule 1 is mandatory. Schedules 2, 3, and 4 are optional. For each policy schedule that you add, do the following:
 - a. In the **Schedule details** section do the following:
 - i. For **Schedule name**, specify a descriptive name for the schedule.

- ii. For **Frequency** and the related fields, configure the interval between policy runs. You can configure policy runs on a daily, weekly, monthly, or yearly schedule. Alternatively, choose **Custom cron expression** to specify an interval of up to one year. For more information, see [Cron expressions](#) in the *Amazon CloudWatch Events User Guide*.
- iii. For **Starting at**, specify the time to start the policy runs. The first policy run starts within an hour after the time that you schedule. You must enter the time in the hh:mm UTC format.
- iv. For **Retention type**, specify the retention policy for AMIs created by the schedule. You can retain AMIs based on either their total count or their age.

For count-based retention, the range is 1 to 1000. After the maximum count is reached, the oldest AMI is deregistered when a new one is created.

For age-based retention, the range is 1 day to 100 years. After the retention period of each AMI expires, it is deregistered.

Note

All schedules must have the same retention type. You can specify the retention type for Schedule 1 only. Schedules 2, 3, and 4 inherit the retention type from Schedule 1. Each schedule can have its own retention count or period.

- b. In the **Tagging** section, do the following:

- i. To copy all of the user-defined tags from the source instance to the AMIs created by the schedule, select **Copy tags from source**.
 - ii. By default, AMIs created by the schedule are automatically tagged with the ID of the source instance. To prevent this automatic tagging from happening, for **Variable tags**, remove the `instance-id:$({instance-id})` tile.
 - iii. To specify additional tags to assign to AMIs created by this schedule, choose **Add tags**.
- c. To deprecate AMIs when they should no longer be used, in the **AMI deprecation** section, select **Enable AMI deprecation for this schedule** and then specify the AMI deprecation rule. The AMI deprecation rule specifies when AMIs are to be deprecated.

If the schedule uses count-based AMI retention, you must specify the number of oldest AMIs to deprecate. The deprecation count must be less than or equal to the schedule's AMI retention count, and it can't be greater than 1000. For example, if the schedule is configured to retain a maximum of 5 AMIs, then you can configure the scheduled to deprecate up to old 5 oldest AMIs.

If the schedule uses age-based AMI retention, you must specify the period after which AMIs are to be deprecated. The deprecation count must be less than or equal to the schedule's AMI retention period, and it can't be greater than 10 years (120 months, 520 weeks, or 3650 days). For example, if the schedule is configured to retain AMIs for 10 days, then you can configure the scheduled to deprecate AMIs after periods up to 10 days after creation.

- d. To copy AMIs created by the schedule to different Regions, in the **Cross-Region copy** section, select **Enable cross-Region copy**. You can copy AMIs to up to three additional Regions in your account. You must specify a separate cross-Region copy rule for each destination Region.

For each destination Region, you can specify the following:

- A retention policy for the AMI copy. When the retention period expires, the copy in the destination Region is automatically deregistered.
- Encryption status for the AMI copy. If the source AMI is encrypted, or if encryption by default is enabled, the copied AMIs are always encrypted. If the source AMI is unencrypted and encryption by default is disabled, you can optionally enable encryption. If you do not specify a KMS key, the AMIs are encrypted using the default KMS key for

EBS encryption in each destination Region. If you specify a KMS key for the destination Region, then the selected IAM role must have access to the KMS key.

- A deprecation rule for the AMI copy. When the deprecation period expires, the AMI copy is automatically deprecated. The deprecation period must be less than or equal to the copy retention period, and it can't be greater than 10 years.
- Whether to copy all tags or no tags from the source AMI.

Note

Do not exceed the number of concurrent AMI copies per Region.

- To add additional schedules, choose **Add another schedule**, which is located at the top of the screen. For each additional schedule, complete the fields as described previously in this topic.
- After you have added the required schedules, choose **Review policy**.

12. Review the policy summary, and then choose **Create policy**.

Command line

Use the [create-lifecycle-policy](#) command to create an AMI lifecycle policy. For PolicyType, specify IMAGE_MANAGEMENT.

Note

To simplify the syntax, the following examples use a JSON file, policyDetails.json, that includes the policy details.

Example 1: Age-based retention and AMI deprecation

This example creates an AMI lifecycle policy that creates AMIs of all instances that have a tag key of purpose with a value of production without rebooting the targeted instances. The policy includes one schedule that creates an AMI every day at 01:00 UTC. The policy retains AMIs for 2 days and deprecates them after 1 day. It also copies the tags from the source instance to the AMIs that it creates.

```
aws dlm create-lifecycle-policy \
--description "My AMI policy" \
--state ENABLED \
--execution-role-arn
arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRoleForAMIManagement \
--policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```
{
  "PolicyType": "IMAGE_MANAGEMENT",
  "ResourceTypes": [
    "INSTANCE"
  ],
  "TargetTags": [
    {
      "Key": "purpose",
      "Value": "production"
    }
  ],
  "Schedules": [
    {
      "Name": "DailyAMIs",
      "TagsToAdd": [
        {
          "Key": "type",
          "Value": "myDailyAMI"
        }
      ],
      "CreateRule": {
        "Interval": 24,
        "Start": "01:00"
      }
    }
  ]
}
```

```
        "IntervalUnit": "HOURS",
        "Times": [
            "01:00"
        ]
    },
    "RetainRule": {
        "Interval": 2,
        "IntervalUnit": "DAYS"
    },
    "DeprecateRule": {
        "Interval": 1,
        "IntervalUnit": "DAYS"
    },
    "CopyTags": true
},
"Parameters": {
    "NoReboot": true
}
}
```

If the request succeeds, the command returns the ID of the newly created policy. The following is example output.

```
{
    "PolicyId": "policy-9876543210abcdef0"
```

Example 2: Count-based retention and AMI deprecation with cross-Region copy

This example creates an AMI lifecycle policy that creates AMIs of all instances that have a tag key of purpose with a value of production and reboots the target instances. The policy includes one schedule that creates an AMI every 6 hours starting at 17:30 UTC. The policy retains 3 AMIs and automatically deprecates the 2 oldest AMIs. It also has a cross-Region copy rule that copies AMIs to us-east-1, retains 2 AMI copies, and automatically deprecates the oldest AMI.

```
aws dlm create-lifecycle-policy \
--description "My AMI Policy" \
--state ENABLED \
--execution-role-arn
arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRoleForAMIManagement \
--policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```
{
    "PolicyType": "IMAGE_MANAGEMENT",
    "ResourceTypes": [
        "INSTANCE"
    ],
    "TargetTags": [
        {
            "Key": "purpose",
            "Value": "production"
        }
    ],
    "Parameters": {
        "NoReboot": true
    },
    "Schedules": [
        {
            "Name": "Schedule1",
            "CopyTags": true,
            "CreateRule": {
                "Interval": 6,
```

```
        "IntervalUnit": "HOURS",
        "Times" : ["17:30"]
    },
    "RetainRule":{
        "Count" : 3
    },
    "DeprecateRule":{
        "Count" : 2
    },
    "CrossRegionCopyRules": [
        {
            "TargetRegion": "us-east-1",
            "Encrypted": true,
            "RetainRule":{
                "IntervalUnit": "DAYS",
                "Interval": 2
            },
            "DeprecateRule":{
                "IntervalUnit": "DAYS",
                "Interval": 1
            },
            "CopyTags": true
        }
    ]
}
```

Considerations for AMI lifecycle policies

The following **general considerations** apply to creating AMI lifecycle policies:

- AMI lifecycle policies target only instances that are in the same Region as the policy.
- The first AMI creation operation starts within one hour after the specified start time. Subsequent AMI creation operations start within one hour of their scheduled time.
- When Amazon Data Lifecycle Manager deregisters an AMI, it automatically deletes its backing snapshots.
- Target resource tags are case sensitive.
- If you remove the target tags from an instance that is targeted by a policy, Amazon Data Lifecycle Manager no longer manages existing AMIs in the standard; you must manually delete them if they are no longer needed.
- You can create multiple policies to back up an instance. For example, if an instance has two tags, where tag A is the target for policy A to create an AMI every 12 hours, and tag B is the target for policy B to create an AMI every 24 hours, Amazon Data Lifecycle Manager creates AMIs according to the schedules for both policies. Alternatively, you can achieve the same result by creating a single policy that has multiple schedules. For example, you can create a single policy that targets only tag A, and specify two schedules — one for every 12 hours and one for every 24 hours.
- New volumes that are attached to a target instance after the policy has been created are automatically included in the backup at the next policy run. All volumes attached to the instance at the time of the policy run are included.
- If you create a policy with a custom cron-based schedule that is configured to create only one AMI, the policy will not automatically deregister that AMI when the retention threshold is reached. You must manually deregister the AMI if it is no longer needed.
- If you create an age-based policy where the retention period is shorter than the creation frequency, Amazon Data Lifecycle Manager will always retain the last AMI until the next one is created. For example, if an age-based policy creates one AMI every month with a retention period of seven days, Amazon Data Lifecycle Manager will retain each AMI for one month, even though the retention period is seven days.
- For count-based policies, Amazon Data Lifecycle Manager always creates AMIs according to the creation frequency before attempting to deregister the oldest AMI according to the retention policy.

- It can take several hours to successfully deregister an AMI and to delete its associated backing snapshots. If Amazon Data Lifecycle Manager creates the next AMI before the previously created AMI is successfully deregistered, you could temporarily retain a number of AMIs that is greater than your retention count.

The following considerations apply to **terminating instances targeted by a policy**:

- If you terminate an instance that was targeted by a policy with a count-based retention schedule, the policy no longer manages the AMIs that it previously created from the terminated instance. You must manually deregister those earlier AMIs if they are no longer needed.
- If you terminate an instance that was targeted by a policy with an age-based retention schedule, the policy continues to deregister AMIs that were previously created from the terminated instance on the defined schedule, up to, but not including, the last AMI. You must manually deregister the last AMI if it is no longer needed.

The following considerations apply to AMI policies and **AMI deprecation**:

- If you increase the AMI deprecation count for a schedule with count-based retention, the change is applied to all AMIs (existing and new) created by the schedule.
- If you increase the AMI deprecation period for a schedule with age-based retention, the change is applied to new AMIs only. Existing AMIs are not affected.
- If you remove the AMI deprecation rule from a schedule, Amazon Data Lifecycle Manager will not cancel deprecation for AMIs that were previously deprecated by that schedule.
- If you decrease the AMI deprecation count or period for a schedule, Amazon Data Lifecycle Manager will not cancel deprecation for AMIs that were previously deprecated by that schedule.
- If you manually deprecate an AMI that was created by an AMI policy, Amazon Data Lifecycle Manager will not override the deprecation.
- If you manually cancel deprecation for an AMI that was previously deprecated by an AMI policy, Amazon Data Lifecycle Manager will not override the cancellation.
- If an AMI is created by multiple conflicting schedules, and one or more of those schedules do not have an AMI deprecation rule, Amazon Data Lifecycle Manager will not deprecate that AMI.
- If an AMI is created by multiple conflicting schedules, and all of those schedules have an AMI deprecation rule, Amazon Data Lifecycle Manager will use the deprecation rule that results in the latest deprecation date.

The following considerations apply to AMI policies and [Recycle Bin \(p. 2045\)](#):

- If Amazon Data Lifecycle Manager deregisters an AMI and sends it to the Recycle Bin when the policy's retention threshold is reached, and you manually restore that AMI from the Recycle Bin, you must manually deregister the AMI when it is no longer needed. Amazon Data Lifecycle Manager will no longer manage the AMI.
- If you manually deregister an AMI that was created by a policy, and that AMI is in the Recycle Bin when the policy's retention threshold is reached, Amazon Data Lifecycle Manager will not deregister the AMI. Amazon Data Lifecycle Manager does not manage AMIs while they are in the Recycle Bin.

If the AMI is restored from the Recycle Bin before the policy's retention threshold is reached, Amazon Data Lifecycle Manager will deregister the AMI when the policy's retention threshold is reached.

If the AMI is restored from the Recycle Bin after the policy's retention threshold is reached, Amazon Data Lifecycle Manager will no longer deregister the AMI. You must manually delete it when it is no longer needed.

The following considerations apply to AMI policies that are in the **error** state:

- For policies with age-based retention schedules, AMIs that are set to expire while the policy is in the `error` state are retained indefinitely. You must deregister the AMIs manually. When you re-enable the policy, Amazon Data Lifecycle Manager resumes deregistering AMIs as their retention periods expire.
- For policies with count-based retention schedules, the policy stops creating and deregistering AMIs while it is in the `error` state. When you re-enable the policy, Amazon Data Lifecycle Manager resumes creating AMIs, and it resumes deregistering AMIs as the retention threshold is met.

Additional resources

For more information, see the [Automating Amazon EBS snapshot and AMI management using Amazon Data Lifecycle Manager](#) AWS storage blog.

Automate cross-account snapshot copies

Automating cross-account snapshot copies enables you to copy your Amazon EBS snapshots to specific Regions in an isolated account and encrypt those snapshots with an encryption key. This enables you to protect yourself against data loss in the event of your account being compromised.

Automating cross-account snapshot copies involves two accounts:

- **Source account**—The source account is the account that creates and shares the snapshots with the target account. In this account, you must create an EBS snapshot policy that creates snapshots at set intervals and then shares them with other AWS accounts.
- **Target account**—The target account is the account with destination account with which the snapshots are shared, and it is the account that creates copies of the shared snapshots. In this account, you must create a cross-account copy event policy that automatically copies snapshots that are shared with it by one or more specified source accounts.

Create cross-account snapshot copy policies

To prepare the source and target accounts for cross-account snapshot copying, you need to perform the following steps:

Topics

- [Step 1: Create the EBS snapshot policy \(Source account\) \(p. 1881\)](#)
- [Step 2: Share the customer managed key \(Source account\) \(p. 1882\)](#)
- [Step 3: Create cross-account copy event policy \(Target account\) \(p. 1883\)](#)
- [Step 4: Allow IAM role to use the required KMS keys \(Target account\) \(p. 1886\)](#)

Step 1: Create the EBS snapshot policy (Source account)

In the source account, create an EBS snapshot policy that will create the snapshots and share them with the required target accounts.

When you create the policy, ensure that you enable cross-account sharing and that you specify the target AWS accounts with which to share the snapshots. These are the accounts with which the snapshots are to be shared. If you are sharing encrypted snapshots, then you must give the selected target accounts

permission to use the KMS key used to encrypt the source volume. For more information, see [Step 2: Share the customer managed key \(Source account\) \(p. 1882\)](#).

Note

You can only share snapshots that are unencrypted or that are encrypted using a customer managed key. You can't share snapshots that are encrypted with the default EBS encryption KMS key. If you share encrypted snapshots, then you must also share the KMS key that was used to encrypt the source volume with the target accounts. For more information, see [Allowing users in other accounts to use a KMS key](#) in the *AWS Key Management Service Developer Guide*.

For more information about creating an EBS snapshot policy, see [Automate snapshot lifecycles \(p. 1862\)](#).

Use one of the following methods to create the EBS snapshot policy.

Step 2: Share the customer managed key (Source account)

If you are sharing encrypted snapshots, you must grant the IAM role and the target AWS accounts (that you selected in the previous step) permissions to use the customer managed key that was used to encrypt the source volume.

Note

Perform this step only if you are sharing encrypted snapshots. If you are sharing unencrypted snapshots, skip this step.

Console

1. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed key** and then select the KMS key that you need to share with the target accounts.

Make note of the KMS key ARN, you'll need this later.

4. On the **Key policy** tab, scroll down to the **Key users** section. Choose **Add**, enter the name of the IAM role that you selected in the previous step, and then choose **Add**.
5. On the **Key policy** tab, scroll down to the **Other AWS accounts** section. Choose **Add other AWS accounts**, and then add all of the target AWS accounts that you chose to share the snapshots with in the previous step.
6. Choose **Save changes**.

Command line

Use the [get-key-policy](#) command to retrieve the key policy that is currently attached to the KMS key.

For example, the following command retrieves the key policy for a KMS key with an ID of 9d5e2b3d-e410-4a27-a958-19e220d83a1e and writes it to a file named `snapshotKey.json`.

```
$ aws kms get-key-policy \
--policy-name default \
--key-id 9d5e2b3d-e410-4a27-a958-19e220d83a1e \
--query Policy \
--output text > snapshotKey.json
```

Open the key policy using your preferred text editor. Add the ARN of the IAM role that you specified when you created the snapshot policy and the ARNs of the target accounts with which to share the KMS key.

For example, in the following policy, we added the ARN of the default IAM role, and the ARN of the root account for target account 222222222222.

Tip

To follow the principle of least privilege, do not allow full access to kms:CreateGrant. Instead, use the kms:GrantIsForAWSResource condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

```
{  
    "Sid" : "Allow use of the key",  
    "Effect" : "Allow",  
    "Principal" : {  
        "AWS" : [  
            "arn:aws:iam::111111111111:role/service-role/  
AWSDataLifecycleManagerDefaultRole",  
            "arn:aws:iam::222222222222:root"  
        ]  
    },  
    "Action" : [  
        "kms:Encrypt",  
        "kms:Decrypt",  
        "kms:ReEncrypt*",  
        "kms:GenerateDataKey*",  
        "kms:DescribeKey"  
    ],  
    "Resource" : "*"  
},  
{  
    "Sid" : "Allow attachment of persistent resources",  
    "Effect" : "Allow",  
    "Principal" : {  
        "AWS" : [  
            "arn:aws:iam::111111111111:role/service-role/  
AWSDataLifecycleManagerDefaultRole",  
            "arn:aws:iam::222222222222:root"  
        ]  
    },  
    "Action" : [  
        "kms>CreateGrant",  
        "kms>ListGrants",  
        "kms:RevokeGrant"  
    ],  
    "Resource" : "*",  
    "Condition" : {  
        "Bool" : {  
            "kms:GrantIsForAWSResource" : "true"  
        }  
    }  
}
```

Save and close the file. Then use the [put-key-policy](#) command to attach the updated key policy to the KMS key.

```
$ aws kms put-key-policy \  
--policy-name default \  
--key-id 9d5e2b3d-e410-4a27-a958-19e220d83a1e \  
--policy file://snapshotKey.json
```

Step 3: Create cross-account copy event policy (*Target account*)

In the target account, you must create a cross-account copy event policy that will automatically copy snapshots that are shared by the required source accounts.

This policy runs in the target account only when one of the specified source accounts shares snapshot with the account.

Use one of the following methods to create the cross-account copy event policy.

Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Elastic Block Store, Lifecycle Manager**, and then choose **Create lifecycle policy**.
3. On the **Select policy type** screen, choose **Cross-account copy event policy**, and then choose **Next**.
4. For **Policy description**, enter a brief description for the policy.
5. For **Policy tags**, add the tags to apply to the lifecycle policy. You can use these tags to identify and categorize your policies.
6. In the **Event settings** section, define the snapshot sharing event that will cause the policy to run. Do the following:
 - a. For **Sharing accounts**, specify the source AWS accounts from which you want to copy the shared snapshots. Choose **Add account**, enter the 12-digit AWS account ID, and then choose **Add**.
 - b. For **Filter by description**, enter the required snapshot description using a regular expression. Only snapshots that are shared by the specified source accounts and that have descriptions that match the specified filter are copied by the policy. For more information, see [Specify snapshot description filters \(p. 1888\)](#).
7. For **IAM role**, choose the IAM role that has permissions to perform snapshot copy actions. To use the default role provided by Amazon Data Lifecycle Manager, choose **Default role**. Alternatively, to use a custom IAM role that you previously created, choose **Choose another role** and then select the role to use.

If you are copying encrypted snapshots, you must grant the selected IAM role permissions to use the encryption KMS key used to encrypt the source volume. Similarly, if you are encrypting the snapshot in the destination Region using a different KMS key, you must grant the IAM role permission to use the destination KMS key. For more information, see [Step 4: Allow IAM role to use the required KMS keys \(Target account\) \(p. 1886\)](#).

8. In the **Copy action** section, define the snapshot copy actions that the policy should perform when it is activated. The policy can copy snapshots to up to three Regions. You must specify a separate copy rule for each destination Region. For each rule that you add, do the following:
 - a. For **Name**, enter a descriptive name for the copy action.
 - b. For **Target Region**, select the Region to which to copy the snapshots.
 - c. For **Expire**, specify how long to retain the snapshot copies in the target Region after creation.
 - d. To encrypt the snapshot copy, for **Encryption**, select **Enable encryption**. If the source snapshot is encrypted, or if encryption by default is enabled for your account, the snapshot copy is always encrypted, even if you do not enable encryption here. If the source snapshot is unencrypted and encryption by default is not enabled for your account, you can choose to enable or disable encryption. If you enable encryption, but do not specify a KMS key, the snapshots are encrypted using the default encryption KMS key in each destination Region. If you specify a KMS key for the destination Region, you must have access to the KMS key.
9. To add additional snapshot copy actions, choose **Add new Regions**.
10. For **Policy status after creation**, choose **Enable policy** to start the policy runs at the next scheduled time, or **Disable policy** to prevent the policy from running. If you do not enable the policy now, it will not start copying snapshots until you manually enable it after creation.
11. Choose **Create policy**.

Command line

Use the [create-lifecycle-policy](#) command to create a policy. To create a cross-account copy event policy, for PolicyType, specify EVENT_BASED_POLICY.

For example, the following command creates a cross-account copy event policy in target account 222222222222. The policy copies snapshots that are shared by source account 111111111111. The policy copies snapshots to sa-east-1 and eu-west-2. Snapshots copied to sa-east-1 are unencrypted and they are retained for 3 days. Snapshots copied to eu-west-2 are encrypted using KMS key 8af79514-350d-4c52-bac8-8985e84171c7 and they are retained for 1 month. The policy uses the default IAM role.

```
$ aws dlm create-lifecycle-policy \
  --description "Copy policy" \
  --state ENABLED \
  --execution-role-arn arn:aws:iam::222222222222:role/service-role/
AWSDataLifecycleManagerDefaultRole \
  --policy-details file://policyDetails.json
```

The following shows the contents of the policyDetails.json file.

```
{
    "PolicyType" : "EVENT_BASED_POLICY",
    "EventSource" : {
        "Type" : "MANAGED_CWE",
        "Parameters": {
            "EventType" : "shareSnapshot",
            "SnapshotOwner": ["111111111111"]
        }
    },
    "Actions" : [
        {
            "Name" :"Copy Snapshot to Sao Paulo and London",
            "CrossRegionCopy" : [
                {
                    "Target" : "sa-east-1",
                    "EncryptionConfiguration" : {
                        "Encrypted" : false
                    },
                    "RetainRule" : {
                        "Interval" : 3,
                        "IntervalUnit" : "DAYS"
                    }
                },
                {
                    "Target" : "eu-west-2",
                    "EncryptionConfiguration" : {
                        "Encrypted" : true,
                        "CmkArn" : "arn:aws:kms:eu-west-2:222222222222:key/8af79514-350d-4c52-
bac8-8985e84171c7"
                    },
                    "RetainRule" : {
                        "Interval" : 1,
                        "IntervalUnit" : "MONTHS"
                    }
                }
            ]
        }
    ]
}
```

If the request succeeds, the command returns the ID of the newly created policy. The following is example output.

```
{
    "PolicyId": "policy-9876543210abcdef0"
```

}

Step 4: Allow IAM role to use the required KMS keys (*Target account*)

If you are copying encrypted snapshots, you must grant the IAM role (that you selected in the previous step) permissions to use the customer managed key that was used to encrypt the source volume.

Note

Only perform this step if you are copying encrypted snapshots. If you are copying unencrypted snapshots, skip this step.

Use one of the following methods to add the required policies to the IAM role.

Console

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, select **Roles**. Search for and select the IAM role that you selected when you created the cross-account copy event policy in the previous step. If you chose to use the default role, the role is named **AWSDataLifecycleManagerDefaultRole**.
3. Choose **Add inline policy** and then select the **JSON** tab.
4. Replace the existing policy with the following, and specify the ARN of the KMS key that was used to encrypt the source volumes and that was shared with you by the source account in Step 2.

Note

If you are copying from multiple source accounts, then you must specify the corresponding KMS key ARN from each source account.

In the following example, the policy grants the IAM role permission to use KMS key 1234abcd-12ab-34cd-56ef-1234567890ab, which was shared by source account 111111111111, and KMS key 4567dcba-23ab-34cd-56ef-0987654321yz, which exists in target account 222222222222.

Tip

To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the `kms:GrantIsForAWSResource` condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "kms:RevokeGrant",  
                "kms>CreateGrant",  
                "kms>ListGrants"  
            ],  
            "Resource": [  
                "arn:aws:kms:us-east-1:111111111111:key/1234abcd-12ab-34cd-56ef-1234567890ab",  
                "arn:aws:kms:us-east-1:222222222222:key/4567dcba-23ab-34cd-56ef-0987654321yz"  
            ],  
            "Condition": {  
                "Bool": {  
                    "kms:GrantIsForAWSResource": "true"  
                }  
            }  
        }  
    ]  
}
```

```
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*",
                "kms:DescribeKey"
            ],
            "Resource": [
                "arn:aws:kms:us-east-1:111111111111:key/1234abcd-12ab-34cd-56ef-1234567890ab",
                "arn:aws:kms:us-east-1:222222222222:key/4567dcba-23ab-34cd-56ef-0987654321yz"
            ]
        }
    ]
```

5. Choose **Review policy**

6. For **Name**, enter a descriptive name for the policy, and then choose **Create policy**.

Command line

Using your preferred text editor, create a new JSON file named `policyDetails.json`. Add the following policy and specify the ARN of the KMS key that was used to encrypt the source volumes and that was shared with you by the source account in Step 2.

Note

If you are copying from multiple source accounts, then you must specify the corresponding KMS key ARN from each source account.

In the following example, the policy grants the IAM role permission to use KMS key `1234abcd-12ab-34cd-56ef-1234567890ab`, which was shared by source account `111111111111`, and KMS key `4567dcba-23ab-34cd-56ef-0987654321yz`, which exists in target account `222222222222`.

Tip

To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the `kms:GrantIsForAWSResource` condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kms:RevokeGrant",
                "kms:CreateGrant",
                "kms>ListGrants"
            ],
            "Resource": [
                "arn:aws:kms:us-east-1:111111111111:key/1234abcd-12ab-34cd-56ef-1234567890ab",
                "arn:aws:kms:us-east-1:222222222222:key/4567dcba-23ab-34cd-56ef-0987654321yz"
            ],
            "Condition": {
                "Bool": {
                    "kms:GrantIsForAWSResource": "true"
                }
            }
        }
    ]
}
```

```
        "kms:GrantIsForAWSResource": "true"
    }
},
{
    "Effect": "Allow",
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
    ],
    "Resource": [
        "arn:aws:kms:us-
east-1:111111111111:key/1234abcd-12ab-34cd-56ef-1234567890ab",
        "arn:aws:kms:us-
east-1:222222222222:key/4567dcba-23ab-34cd-56ef-0987654321yz"
    ]
}
}
```

Save and close the file. Then use the [put-role-policy](#) command to add the policy to the IAM role.

For example

```
$ aws iam put-role-policy \
--role-name AWSDataLifecycleManagerDefaultRole \
--policy-name CopyPolicy \
--policy-document file://AdminPolicy.json
```

Specify snapshot description filters

When you create the snapshot copy policy in the target account, you must specify a snapshot description filter. The snapshot description filter enables you to specify an additional level of filtering that lets you control which snapshots are copied by the policy. This means that a snapshot is only copied by the policy if it is shared by one of the specified source accounts, and it has a snapshot description that matches the specified filter. In other words, if a snapshot is shared by one of the specified source accounts, but it does not have a description that matches the specified filter, it is not copied by the policy.

The snapshot filter description must be specified using a regular expression. It is a mandatory field when creating cross-account copy event policies using the console and the command line. The following are example regular expressions that can be used:

- `.*`—This filter matches all snapshot descriptions. If you use this expression the policy will copy all snapshots that are shared by one of the specified source accounts.
- `Created for policy: policy-0123456789abcdef0.*`—This filter matches only snapshots that are created by a policy with an ID of `policy-0123456789abcdef0`. If you use an expression like this, only snapshots that are shared with your account by one of the specified source accounts, and that have been created by a policy with the specified ID are copied by the policy.
- `.*production.*`—This filter matches any snapshot that has the word `production` anywhere in its description. If you use this expression the policy will copy all snapshots that are shared by one of the specified source accounts and that have the specified text in their description.

Considerations for cross-account snapshot copy policies

The following considerations apply to cross-account copy event policies:

- You can only copy snapshots that are unencrypted or that are encrypted using a customer managed key.
- You can create a cross-account copy event policy to copy snapshots that are shared outside of Amazon Data Lifecycle Manager.
- If you want to encrypt snapshots in the target account, then the IAM role selected for the cross-account copy event policy must have permission to use the required KMS key.

Additional resources

For more information, see the [Automating copying encrypted Amazon EBS snapshots across AWS accounts](#) AWS storage blog.

View, modify, and delete lifecycle policies

Use the following procedures to view, modify and delete existing lifecycle policies.

Topics

- [View lifecycle policies \(p. 1889\)](#)
- [Modify lifecycle policies \(p. 1890\)](#)
- [Delete lifecycle policies \(p. 1892\)](#)

View lifecycle policies

Use one of the following procedures to view a lifecycle policy.

Console

To view a lifecycle policy

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Elastic Block Store, Lifecycle Manager**.
3. Select a lifecycle policy from the list. The **Details** tab displays information about the policy.

Command line

Use the [get-lifecycle-policy](#) command to display information about a lifecycle policy.

```
aws dlm get-lifecycle-policy --policy-id policy-0123456789abcdef0
```

The following is example output. It includes the information that you specified, plus metadata inserted by AWS.

```
{  
    "Policy": {  
        "Description": "My first policy",  
        "DateCreated": "2018-05-15T00:16:21+0000",  
        "State": "ENABLED",  
        "ExecutionRoleArn":  
            "arn:aws:iam::210774411744:role/AWSDataLifecycleManagerDefaultRole",  
        "PolicyId": "policy-0123456789abcdef0",  
        "DateModified": "2018-05-15T00:16:22+0000",  
        "PolicyDetails": {  
            "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",  
            "ResourceTypes": [  
                "VOLUME"  
            ],  
        },  
    },  
}
```

```
"TargetTags": [
    {
        "Value": "115",
        "Key": "costcenter"
    }
],
"Schedules": [
    {
        "TagsToAdd": [
            {
                "Value": "myDailySnapshot",
                "Key": "type"
            }
        ],
        "RetainRule": {
            "Count": 5
        },
        "CopyTags": false,
        "CreateRule": {
            "Interval": 24,
            "IntervalUnit": "HOURS",
            "Times": [
                "03:00"
            ]
        },
        "Name": "DailySnapshots"
    }
]
```

Modify lifecycle policies

Considerations for modifying policies

- If you modify an AMI or snapshot policy by removing its target tags, the volumes or instances with those tags are no longer managed by the policy.
- If you modify a schedule name, the snapshots or AMIs created under the old schedule name are no longer managed by the policy.
- If you modify an age-based retention schedule to use a new time interval, the new interval is used only for new snapshots or AMIs created after the change. The new schedule does not affect the retention schedule of snapshots or AMIs created before the change.
- You cannot change the retention schedule of a policy from count-based to age-based after creation. To make this change, you must create a new policy.
- If you disable a policy with an age-based retention schedule, the snapshots or AMIs that are set to expire while the policy is disabled are retained indefinitely. You must delete the snapshots or deregister the AMIs manually. When you re-enable the policy, Amazon Data Lifecycle Manager resumes deleting snapshots or deregistering AMIs as their retention periods expire.
- If you disable a policy with a count-based retention schedule, the policy stops creating and deleting snapshots or AMIs. When you re-enable the policy, Amazon Data Lifecycle Manager resumes creating snapshots and AMIs, and it resumes deleting snapshots or AMIs as the retention threshold is met.
- If you disable a policy that has a snapshot archiving-enabled policy, snapshots that are in the archive tier at the time of disabling the policy are no longer managed by Amazon Data Lifecycle Manager. You must manually delete the snapshot if they are no longer needed.
- If you enable snapshot archiving on a count-based schedule, the archiving rule applies to all new snapshots that are created and archived by the schedule, and also applies to existing snapshots that were previously created and archived by the schedule.

- If you enable snapshot archiving on an age-based schedule, the archiving rule applies only to new snapshots created after enabling snapshot archiving. Existing snapshots created before enabling snapshot archiving continue to be deleted from their respective storage tiers, according to the schedule set when those snapshots were originally created and archived.
- If you disable snapshot archiving for a count-based schedule, the schedule immediately stops archiving snapshots. Snapshots that were previously archived by the schedule remain in the archive tier and they will not be deleted by Amazon Data Lifecycle Manager.
- If you disable snapshot archiving for an age-based schedule, the snapshots created by the policy and that are scheduled to be archived are permanently deleted at the scheduled archive date and time, as indicated by the `aws:dlm:expirationTime` system tag.
- If you disable snapshot archiving for a schedule, the schedule immediately stops archiving snapshots. Snapshots that were previously archived by the schedule remain in the archive tier and they will not be deleted by Amazon Data Lifecycle Manager.
- If you modify the archive retention count for a count-based schedule, the new retention count includes existing snapshots that were previously archived by the schedule.
- If you modify the archive retention period for an age-based schedule, the new retention period applies only to snapshots that are archived after modifying the retention rule.

Use one of the following procedures to modify a lifecycle policy.

Console

To modify a lifecycle policy

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Elastic Block Store, Lifecycle Manager**.
3. Select a lifecycle policy from the list.
4. Choose **Actions, Modify Lifecycle Policy**.
5. Modify the policy settings as needed. For example, you can modify the schedule, add or remove tags, or enable or disable the policy.
6. Choose **Update policy**.

Command line

Use the [update-lifecycle-policy](#) command to modify the information in a lifecycle policy. To simplify the syntax, this example references a JSON file, `policyDetailsUpdated.json`, that includes the policy details.

```
aws dlm update-lifecycle-policy \
--state DISABLED \
--execution-role-arn
arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole" \
--policy-details file://policyDetailsUpdated.json
```

The following is an example of the `policyDetailsUpdated.json` file.

```
{
    "ResourceTypes": [
        "VOLUME"
    ],
    "TargetTags": [
        {
            "Key": "costcenter",
            "Value": "120"
        }
    ]
}
```

```
],
"Schedules": [
  {
    "Name": "DailySnapshots",
    "TagsToAdd": [
      {
        "Key": "type",
        "Value": "myDailySnapshot"
      }
    ],
    "CreateRule": {
      "Interval": 12,
      "IntervalUnit": "HOURS",
      "Times": [
        "15:00"
      ]
    },
    "RetainRule": {
      "Count": 5
    },
    "CopyTags": false
  }
]
```

To view the updated policy, use the `get-lifecycle-policy` command. You can see that the state, the value of the tag, the snapshot interval, and the snapshot start time were changed.

Delete lifecycle policies

Considerations for modifying policies

- If you delete a policy, the snapshots or AMIs created by that policy are not automatically deleted. If you no longer need the snapshots or AMIs, you must delete them manually.
- If you delete a policy that has a snapshot archiving-enabled policy, snapshots that are in the archive tier at the time of deleting the policy are no longer managed by Amazon Data Lifecycle Manager. You must manually delete the snapshot if they are no longer needed.
- If you delete a policy with an archive-enabled, age-based schedule, the snapshots created by the policy and that are scheduled to be archived are permanently deleted at the scheduled archive date and time, as indicated by the `aws:dlm:expirationtime` system tag.

Use one of the following procedures to delete a lifecycle policy.

Console

To delete a lifecycle policy

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Elastic Block Store, Lifecycle Manager**.
3. Select a lifecycle policy from the list.
4. Choose **Actions, Delete Lifecycle Policy**.
5. When prompted for confirmation, choose **Delete Lifecycle Policy**.

Command line

Use the [delete-lifecycle-policy](#) command to delete a lifecycle policy and free up the target tags specified in the policy for reuse.

Note

You can delete snapshots created only by Amazon Data Lifecycle Manager.

```
aws dlm delete-lifecycle-policy --policy-id policy-0123456789abcdef0
```

The [Amazon Data Lifecycle Manager API Reference](#) provides descriptions and syntax for each of the actions and data types for the Amazon Data Lifecycle Manager Query API.

Alternatively, you can use one of the AWS SDKs to access the API in a way that's tailored to the programming language or platform that you're using. For more information, see [AWS SDKs](#).

AWS Identity and Access Management

Access to Amazon Data Lifecycle Manager requires credentials. Those credentials must have permissions to access AWS resources, such as instances, volumes, snapshots, and AMIs. The following sections provide details about how you can use AWS Identity and Access Management (IAM), and help secure access to your resources.

Topics

- [AWS managed policies \(p. 1893\)](#)
 - [IAM service roles \(p. 1896\)](#)
 - [Permissions for users \(p. 1899\)](#)
 - [Permissions for encryption \(p. 1900\)](#)

AWS managed policies

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases. AWS managed policies make it more efficient for you to assign appropriate permissions to users, groups, and roles, than if you had to write the policies yourself.

However, you can't change the permissions defined in AWS managed policies. AWS occasionally updates the permissions defined in an AWS managed policy. When this occurs, the update affects all principal entities (users, groups, and roles) that the policy is attached to.

Amazon Data Lifecycle Manager provides two AWS managed policies for common use cases. These policies make it more efficient to define the appropriate permissions and control access to your resources. The AWS managed policies provided by Amazon Data Lifecycle Manager are designed to be attached to roles that you pass to Amazon Data Lifecycle Manager.

The following are the AWS managed policies that Amazon Data Lifecycle Manager provides. You can also find these AWS managed policies in the **Policies** section of the IAM console.

AWSDataLifecycleManagerServiceRole

The **AWSDataLifecycleManagerServiceRole** policy provides appropriate permissions to Amazon Data Lifecycle Manager to create and manage Amazon EBS snapshot policies and cross-account copy event policies.

```
"ec2>DeleteSnapshot",
"ec2>DescribeInstances",
"ec2>DescribeVolumes",
"ec2>DescribeSnapshots",
"ec2>EnableFastSnapshotRestores",
"ec2>DescribeFastSnapshotRestores",
"ec2>DisableFastSnapshotRestores",
"ec2>CopySnapshot",
"ec2>ModifySnapshotAttribute",
"ec2>DescribeSnapshotAttribute",
"ec2>ModifySnapshotTier",
"ec2>DescribeSnapshotTierStatus"
],
"Resource": "*"
},
{
"Effect": "Allow",
"Action": [
    "ec2>CreateTags"
],
"Resource": "arn:aws:ec2:*::snapshot/*"
},
{
"Effect": "Allow",
"Action": [
    "events:PutRule",
    "events:DeleteRule",
    "events:DescribeRule",
    "events:EnableRule",
    "events:DisableRule",
    "events>ListTargetsByRule",
    "events:PutTargets",
    "events:RemoveTargets"
],
"Resource": "arn:aws:events:*::*:rule/AwsDataLifecycleRule.managed-cwe.*"
}
]
}
```

AWSDataLifecycleManagerServiceRoleForAMIManagement

The **AWSDataLifecycleManagerServiceRoleForAMIManagement** policy provides appropriate permissions to Amazon Data Lifecycle Manager to create and manage Amazon EBS-backed AMI policies.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2>CreateTags",
            "Resource": [
                "arn:aws:ec2:*::snapshot/*",
                "arn:aws:ec2:*::image/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2>DescribeImages",
                "ec2>DescribeInstances",
                "ec2>DescribeImageAttribute",
                "ec2>DescribeVolumes",
                "ec2>DescribeSnapshots"
            ]
        }
    ]
}
```

```
        ],
        "Resource": "*"
    },
    [
        {
            "Effect": "Allow",
            "Action": "ec2:DeleteSnapshot",
            "Resource": "arn:aws:ec2:*::snapshot/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:ResetImageAttribute",
                "ec2:DeregisterImage",
                "ec2>CreateImage",
                "ec2:CopyImage",
                "ec2:ModifyImageAttribute"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:EnableImageDeprecation",
                "ec2:DisableImageDeprecation"
            ],
            "Resource": "arn:aws:ec2:*::image/*"
        }
    ]
}
```

AWS managed policy updates

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

The following table provides details about updates to AWS managed policies for Amazon Data Lifecycle Manager since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the [Document history \(p. 2242\)](#).

Change	Description	Date
AWSDataLifecycleManagerReadOnlyRole — Added permissions to support snapshot archiving.	Lifecycle Manager added the <code>ec2:ModifySnapshotTier</code> and <code>ec2:DescribeSnapshotTierStatus</code> actions to the grant snapshot policies permission to archive snapshots and to check the archive status for snapshots.	September 30, 2022

Change	Description	Date
AWSDataLifecycleManagerDefaultRoleForAMIManagement — Added permissions to support AMI deprecation.	Lifecycle Manager added the ec2:EnableImageDeprecation and ec2:DisableImageDeprecation actions to grant EBS-backed AMI policies permission to enable and disable AMI deprecation.	August 23, 2021
Amazon Data Lifecycle Manager started tracking changes	Amazon Data Lifecycle Manager started tracking changes for its AWS managed policies.	August 23, 2021

IAM service roles

An AWS Identity and Access Management (IAM) role is similar to a user, in that it is an AWS identity with permissions policies that determine what the identity can and can't do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. A service role is a role that an AWS service assumes to perform actions on your behalf. As a service that performs backup operations on your behalf, Amazon Data Lifecycle Manager requires that you pass it a role to assume when performing policy operations on your behalf. For more information about IAM roles, see [IAM Roles](#) in the *IAM User Guide*.

The role that you pass to Amazon Data Lifecycle Manager must have an IAM policy with the permissions that enable Amazon Data Lifecycle Manager to perform actions associated with policy operations, such as creating snapshots and AMIs, copying snapshots and AMIs, deleting snapshots, and deregistering AMIs. Different permissions are required for each of the Amazon Data Lifecycle Manager policy types. The role must also have Amazon Data Lifecycle Manager listed as a trusted entity, which enables Amazon Data Lifecycle Manager to assume the role.

Topics

- [Default service roles for Amazon Data Lifecycle Manager \(p. 1896\)](#)
- [Custom service roles for Amazon Data Lifecycle Manager \(p. 1897\)](#)

Default service roles for Amazon Data Lifecycle Manager

Amazon Data Lifecycle Manager uses the following default service roles:

- **AWSDataLifecycleManagerDefaultRole**—default role for managing snapshots. It trusts only the dlm.amazonaws.com service to assume the role and it allows Amazon Data Lifecycle Manager to perform the actions required by snapshot and cross-account snapshot copy policies on your behalf. This role uses the `AWSDataLifecycleManagerServiceRole` AWS managed policy.

Note

The ARN format of the role differs depending on whether it was created using the console or the AWS CLI. If the role was created using the console, the ARN format is `arn:aws:iam::account_id:role/service-role/`

AWSDataLifecycleManagerDefaultRole. If the role was created using the AWS CLI, the ARN format is `arn:aws:iam::account_id:role/AWSDataLifecycleManagerDefaultRole`.

- **AWSDataLifecycleManagerDefaultRoleForAMIManagement**—default role for managing AMIs. It trusts only the dlm.amazonaws.com service to assume the role and it allows Amazon Data Lifecycle Manager to perform the actions required by EBS-backed AMI policies on your behalf. This role uses the AWSDataLifecycleManagerServiceRoleForAMIManagement AWS managed policy.

If you are using the Amazon Data Lifecycle Manager console, Amazon Data Lifecycle Manager automatically creates the **AWSDataLifecycleManagerDefaultRole** service role the first time you create a snapshot or cross-account snapshot copy policy, and it automatically creates the **AWSDataLifecycleManagerDefaultRoleForAMIManagement** service role the first time you create an EBS-backed AMI policy.

If you are not using the console, you can manually create the service roles using the [create-default-role](#) command. For `--resource-type`, specify `snapshot` to create `AWSDataLifecycleManagerDefaultRole`, or `image` to create `AWSDataLifecycleManagerDefaultRoleForAMIManagement`.

```
$ aws dlm create-default-role --resource-type snapshot|image
```

If you delete the default service roles, and then need to create them again, you can use the same process to recreate them in your account.

Custom service roles for Amazon Data Lifecycle Manager

As an alternative to using the default service roles, you can create custom IAM roles with the required permissions and then select them when you create a lifecycle policy.

To create a custom IAM role

1. Create roles with the following permissions.
 - Permissions required for managing snapshot lifecycle policies

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ec2:CreateSnapshot",  
                "ec2:CreateSnapshots",  
                "ec2>DeleteSnapshot",  
                "ec2:DescribeInstances",  
                "ec2:DescribeVolumes",  
                "ec2:DescribeSnapshots",  
                "ec2:EnableFastSnapshotRestores",  
                "ec2:DescribeFastSnapshotRestores",  
                "ec2:DisableFastSnapshotRestores",  
                "ec2:CopySnapshot",  
                "ec2:ModifySnapshotAttribute",  
                "ec2:DescribeSnapshotAttribute",  
                "ec2:ModifySnapshotTier",  
                "ec2:DescribeSnapshotTierStatus"  
            ],  
            "Resource": "*"  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ec2:CreateSnapshot",  
                "ec2:CreateSnapshots",  
                "ec2>DeleteSnapshot",  
                "ec2:DescribeInstances",  
                "ec2:DescribeVolumes",  
                "ec2:DescribeSnapshots",  
                "ec2:EnableFastSnapshotRestores",  
                "ec2:DescribeFastSnapshotRestores",  
                "ec2:DisableFastSnapshotRestores",  
                "ec2:CopySnapshot",  
                "ec2:ModifySnapshotAttribute",  
                "ec2:DescribeSnapshotAttribute",  
                "ec2:ModifySnapshotTier",  
                "ec2:DescribeSnapshotTierStatus"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

```
        "ec2:CreateTags"
    ],
    "Resource": "arn:aws:ec2:::snapshot/*"
},
{
    "Effect": "Allow",
    "Action": [
        "events:PutRule",
        "events:DeleteRule",
        "events:DescribeRule",
        "events:EnableRule",
        "events:DisableRule",
        "events>ListTargetsByRule",
        "events:PutTargets",
        "events:RemoveTargets"
    ],
    "Resource": "arn:aws:events::rule/AwsDataLifecycleRule.managed-cwe.*"
}
]
}
```

- Permissions required for managing AMI lifecycle policies

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2>CreateTags",
            "Resource": [
                "arn:aws:ec2:::snapshot/*",
                "arn:aws:ec2:::image/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeImages",
                "ec2:DescribeInstances",
                "ec2:DescribeImageAttribute",
                "ec2:DescribeVolumes",
                "ec2:DescribeSnapshots"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "ec2>DeleteSnapshot",
            "Resource": "arn:aws:ec2:::snapshot/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:ResetImageAttribute",
                "ec2:DeregisterImage",
                "ec2>CreateImage",
                "ec2:CopyImage",
                "ec2:ModifyImageAttribute"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:EnableImageDeprecation",
                "ec2:DeprecateImage"
            ],
            "Resource": "*"
        }
    ]
}
```

```
        "ec2:DisableImageDeprecation"
    ],
    "Resource": "arn:aws:ec2:::image/*"
}
}
```

For more information, see [Creating a Role](#) in the *IAM User Guide*.

2. Add a trust relationship to the roles.
 - a. In the IAM console, choose **Roles**.
 - b. Select the roles that you created, and then choose **Trust relationships**.
 - c. Choose **Edit Trust Relationship**, add the following policy, and then choose **Update Trust Policy**.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "dlm.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

We recommend that you use the `aws:SourceAccount` and `aws:SourceArn` condition keys to protect yourself against the [confused deputy problem](#). For example, you could add the following condition block to the previous trust policy. The `aws:SourceAccount` is the owner of the lifecycle policy and the `aws:SourceArn` is the ARN of the lifecycle policy. If you don't know the lifecycle policy ID, you can replace that portion of the ARN with a wildcard (*) and then update the trust policy after you create the lifecycle policy.

```
"Condition": {
    "StringEquals": {
        "aws:SourceAccount": "account_id"
    },
    "ArnLike": {
        "aws:SourceArn": "arn:partition:dlm:region:account_id:policy/policy_id"
    }
}
```

Permissions for users

A user must have the following permissions to use Amazon Data Lifecycle Manager.

Note

- The `ec2:DescribeAvailabilityZones`, `ec2:DescribeRegions`, `kms>ListAliases`, and `kms:DescribeKey` permissions are required for console users only. If console access is not required, you can remove the permissions.
- The ARN format of the `AWSDataLifecycleManagerDefaultRole` role differs depending on whether it was created using the console or the AWS CLI. If the role was created using the console, the ARN format is `arn:aws:iam::account_id:role/service-role/AWSDataLifecycleManagerDefaultRole`. If the role was created using the AWS CLI, the ARN format is `arn:aws:iam::account_id:role/service-role/AWSDataLifecycleManagerDefaultRole`.

AWSDataLifecycleManagerDefaultRole The following policy assumes the role was created using the AWS CLI.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "dlm:*",  
            "Resource": "*"  
        },  
        {  
            "Effect": "Allow",  
            "Action": "iam:PassRole",  
            "Resource": [  
                "arn:aws:iam::account_id:role/service-role/  
AWSDataLifecycleManagerDefaultRole",  
                "arn:aws:iam::account_id:role/service-role/  
AWSDataLifecycleManagerDefaultRoleForAMIManagement"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": "iam>ListRoles",  
            "Resource": "*"  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ec2:DescribeAvailabilityZones",  
                "ec2:DescribeRegions",  
                "kms>ListAliases",  
                "kms:DescribeKey"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

For more information, see [Changing permissions for a user](#) in the *IAM User Guide*.

Permissions for encryption

Consider the following when working with Amazon Data Lifecycle Manager and encrypted resources.

- If the source volume is encrypted, ensure that the Amazon Data Lifecycle Manager default roles (**AWSDataLifecycleManagerDefaultRole** and **AWSDataLifecycleManagerDefaultRoleForAMIManagement**) have permission to use the KMS keys used to encrypt the volume.
- If you enable **Cross Region copy** for unencrypted snapshots or AMIs backed by unencrypted snapshots, and choose to enable encryption in the destination Region, ensure that the default roles have permission to use the KMS key needed to perform the encryption in the destination Region.
- If you enable **Cross Region copy** for encrypted snapshots or AMIs backed by encrypted snapshots, ensure that the default roles have permission to use both the source and destination KMS keys.
- If you enable snapshot archiving for encrypted snapshots, ensure that the Amazon Data Lifecycle Manager default role (**AWSDataLifecycleManagerDefaultRole**) has permission to use the KMS key used to encrypt the snapshot.

For more information, see [Allowing users in other accounts to use a KMS key](#) in the *AWS Key Management Service Developer Guide*.

Monitor the lifecycle of snapshots and AMIs

You can use the following features to monitor the lifecycle of your snapshots and AMIs.

Features

- [Console and AWS CLI \(p. 1901\)](#)
- [AWS CloudTrail \(p. 1901\)](#)
- [Monitor your policies using CloudWatch Events \(p. 1901\)](#)
- [Monitor your policies using Amazon CloudWatch \(p. 1902\)](#)

Console and AWS CLI

You can view your lifecycle policies using the Amazon EC2 console or the AWS CLI. Each snapshot and AMI created by a policy has a timestamp and policy-related tags. You can filter snapshots and AMIs using these tags to verify that your backups are being created as you intend. For information about viewing lifecycle policies using the console, see [View lifecycle policies \(p. 1889\)](#).

AWS CloudTrail

With AWS CloudTrail, you can track user activity and API usage to demonstrate compliance with internal policies and regulatory standards. For more information, see the [AWS CloudTrail User Guide](#).

Monitor your policies using CloudWatch Events

Amazon EBS and Amazon Data Lifecycle Manager emit events related to lifecycle policy actions. You can use AWS Lambda and Amazon CloudWatch Events to handle event notifications programmatically. Events are emitted on a best effort basis. For more information, see the [Amazon CloudWatch Events User Guide](#).

The following events are available:

Note

No events are emitted for AMI lifecycle policy actions.

- **createSnapshot**—An Amazon EBS event emitted when a CreateSnapshot action succeeds or fails. For more information, see [EventBridge for Amazon EBS \(p. 1985\)](#).
- **DLM Policy State Change**—An Amazon Data Lifecycle Manager event emitted when a lifecycle policy enters an error state. The event contains a description of what caused the error. The following is an example of an event when the permissions granted by the IAM role are insufficient.

```
{  
    "version": "0",  
    "id": "01234567-0123-0123-0123456789ab",  
    "detail-type": "DLM Policy State Change",  
    "source": "aws.dlm",  
    "account": "123456789012",  
    "time": "2018-05-25T13:12:22Z",  
    "region": "us-east-1",  
    "resources": [  
        "arn:aws:dlm:us-east-1:123456789012:policy/policy-0123456789abcdef"  
    ],  
    "detail": {  
        "state": "ERROR",  
    }  
}
```

```
        "cause": "Role provided does not have sufficient permissions",
        "policy_id": "arn:aws:dml:us-east-1:123456789012:policy/policy-0123456789abcdef"
    }
}
```

The following is an example of an event when a limit is exceeded.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "DLM Policy State Change",
    "source": "aws.dlm",
    "account": "123456789012",

        "state": "ERROR",
        "cause": "Maximum allowed active snapshot limit exceeded",
        "policy_id": "arn:aws:dml:us-east-1:123456789012:policy/policy-0123456789abcdef"
    }
}
```

Monitor your policies using Amazon CloudWatch

You can monitor your Amazon Data Lifecycle Manager lifecycle policies using CloudWatch, which collects raw data and processes it into readable, near real-time metrics. You can use these metrics to see exactly how many Amazon EBS snapshots and EBS-backed AMIs are created, deleted, and copied by your policies over time. You can also set alarms that watch for certain thresholds, and send notifications or take actions when those thresholds are met.

Metrics are kept for a period of 15 months, so that you can access historical information and gain a better understanding of how your lifecycle policies perform over an extended period.

For more information about Amazon CloudWatch, see the [Amazon CloudWatch User Guide](#).

Topics

- [Supported metrics \(p. 1902\)](#)
- [View CloudWatch metrics for your policies \(p. 1905\)](#)
- [Graph metrics for your policies \(p. 1906\)](#)
- [Create a CloudWatch alarm for a policy \(p. 1907\)](#)
- [Example use cases \(p. 174\)](#)
- [Managing policies that report failed actions \(p. 1909\)](#)

Supported metrics

The Data Lifecycle Manager namespace includes the following metrics for Amazon Data Lifecycle Manager lifecycle policies. The supported metrics differ by policy type.

All metrics can be measured on the DLMPolicyId dimension. The most useful statistics are sum and average, and the unit of measure is count.

Choose a tab to view the metrics supported by that policy type.

EBS snapshot policies

Metric	Description
ResourcesTargeted	The number of resources targeted by the tags specified in a snapshot or EBS-backed AMI policy.
SnapshotsCreateStart	The number of snapshot create actions initiated by a snapshot policy. Each action is recorded only once, even if there are multiple subsequent retries. If a snapshot create action fails, Amazon Data Lifecycle Manager sends a SnapshotsCreateFailed metric.
SnapshotsCreateCompleted	The number of snapshots created by a snapshot policy. This includes successful retries within 60 minutes of the scheduled time.
SnapshotsCreateFailed	The number of snapshots that could not be created by a snapshot policy. This includes unsuccessful retries within 60 minutes from the scheduled time.
SnapshotsSharedCompleted	The number of snapshots shared across accounts by a snapshot policy.
SnapshotsDeleteCompleted	The number of snapshots deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy. This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.
SnapshotsDeleteFailed	The number of snapshots that could not be deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy. This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.
SnapshotsCopiedRegionStart	The number of cross-Region snapshot copy actions initiated by a snapshot policy.
SnapshotsCopiedRegionCompleted	The number of cross-Region snapshot copies created by a snapshot policy. This includes successful retries within 24 hours of the scheduled time.
SnapshotsCopiedRegionFailed	The number of cross-Region snapshot copies that could not be created by a snapshot policy. This includes unsuccessful retries within 24 hours from the scheduled time.
SnapshotsCopiedRegionDeleted	The number of cross-Region snapshot copies deleted, as designated by the retention rule, by a snapshot policy.
SnapshotsCopiedRegionFailedToDelete	The number of cross-Region snapshot copies that could not be deleted, as designated by the retention rule, by a snapshot policy.
snapshotsArchiveDeleted	The number of archived snapshots that could not be deleted from the archive tier by a snapshot policy.
snapshotsArchiveScheduled	The number of snapshots that were scheduled to be archived by a snapshot policy.

Metric	Description
snapshotsArchiveCompleted	The number of snapshots that were successfully archived by a snapshot policy.
snapshotsArchiveFailed	The number of snapshots that could not be archived by a snapshot policy.
snapshotsArchiveDeleted	The number of archived snapshots that were successfully deleted from the archive tier by a snapshot policy.

EBS-backed AMI policies

The following metrics can be used with EBS-backed AMI policies:

Metric	Description
ResourcesTargeted	The number of resources targeted by the tags specified in a snapshot or EBS-backed AMI policy.
SnapshotsDeleteCompleted	The number of snapshots deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy. This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.
SnapshotsDeleteFailed	The number of snapshots that could not be deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy. This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.
SnapshotsCopiedRegionDeleted	The number of cross-Region snapshot copies deleted, as designated by the retention rule, by a snapshot policy.
SnapshotsCopiedRegionFailed	The number of cross-Region snapshot copies that could not be deleted, as designated by the retention rule, by a snapshot policy.
ImagesCreateStarted	The number of CreateImage actions initiated by an EBS-backed AMI policy.
ImagesCreateCompleted	The number of AMIs created by an EBS-backed AMI policy.
ImagesCreateFailed	The number of AMIs that could not be created by an EBS-backed AMI policy.
ImagesDeregisterCompleted	The number of AMIs deregistered by an EBS-backed AMI policy.
ImagesDeregisterFailed	The number of AMIs that could not be deregistered by an EBS-backed AMI policy.
ImagesCopiedRegionStarted	The number of cross-Region copy actions initiated by an EBS-backed AMI policy.
ImagesCopiedRegionCompleted	The number of cross-Region AMI copies created by an EBS-backed AMI policy.

Metric	Description
ImagesCopiedRegionFailure	The number of cross-Region AMI copies that could not be created by an EBS-backed AMI policy.
ImagesCopiedRegionDeregistered	The number of cross-Region AMI copies deregistered, as designated by the retention rule, by an EBS-backed AMI policy.
ImagesCopiedRegionFailed	The number of cross-Region AMI copies that could not be deregistered, as designated by the retention rule, by an EBS-backed AMI policy.
EnableImageDeprecationCompleted	The number of AMIs that were marked for deprecation by an EBS-backed AMI policy.
EnableImageDeprecationFailed	The number of AMIs that could not be marked for deprecation by an EBS-backed AMI policy.
EnableCopiedImageDeprecationCompleted	The number of cross-Region AMI copies that were marked for deprecation by an EBS-backed AMI policy.
EnableCopiedImageDeprecationFailed	The number of cross-Region AMI copies that could not be marked for deprecation by an EBS-backed AMI policy.

Cross-account copy event policies

The following metrics can be used with cross-account copy event policies:

Metric	Description
SnapshotsCopiedAccountSuccess	The number of cross-account snapshot copy actions initiated by a cross-account copy event policy.
SnapshotsCopiedAccountCompleted	The number of snapshots copied from another account by a cross-account copy event policy. This includes successful retries within 24 hours of the scheduled time.
SnapshotsCopiedAccountFailed	The number of snapshots that could not be copied from another account by a cross-account copy event policy. This includes unsuccessful retries within 24 hours of the scheduled time.
SnapshotsCopiedAccountDeleted	The number of cross-Region snapshot copies deleted, as designated by the retention rule, by a cross-account copy event policy.
SnapshotsCopiedAccountFailedDelete	The number of cross-Region snapshot copies that could not be deleted, as designated by the retention rule, by a cross-account copy event policy.

[View CloudWatch metrics for your policies](#)

You can use the AWS Management Console or the command line tools to list the metrics that Amazon Data Lifecycle Manager sends to Amazon CloudWatch.

Amazon EC2 console

To view metrics using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Lifecycle Manager**.

3. Select a policy in the grid and then choose the **Monitoring** tab.

CloudWatch console

To view metrics using the Amazon CloudWatch console

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. In the navigation pane, choose **Metrics**.
3. Select the **EBS** namespace and then select **Data Lifecycle Manager metrics**.

AWS CLI

To list all the available metrics for Amazon Data Lifecycle Manager

Use the [list-metrics](#) command.

```
C:\> aws cloudwatch list-metrics \
--namespace AWS/EBS
```

To list all the metrics for a specific policy

Use the [list-metrics](#) command and specify the DLMPolicyId dimension.

```
C:\> aws cloudwatch list-metrics \
--namespace AWS/EBS \
--dimensions Name=DLMPolicyId,Value=policy-abcdef01234567890
```

To list a single metric across all policies

Use the [list-metrics](#) command and specify the --metric-name option.

```
C:\> aws cloudwatch list-metrics \
--namespace AWS/EBS \
--metric-name SnapshotsCreateCompleted
```

Graph metrics for your policies

After you create a policy, you can open the Amazon EC2 console and view the monitoring graphs for the policy on the **Monitoring** tab. Each graph is based on one of the available Amazon EC2 metrics.

The following graphs metrics are available:

- Resources targeted (based on `ResourcesTargeted`)
- Snapshot creation started (based on `SnapshotsCreateStarted`)
- Snapshot creation completed (based on `SnapshotsCreateCompleted`)
- Snapshot creation failed (based on `SnapshotsCreateFailed`)
- Snapshot sharing completed (based on `SnapshotsSharedCompleted`)
- Snapshot deletion completed (based on `SnapshotsDeleteCompleted`)
- Snapshot deletion failed (based on `SnapshotsDeleteFailed`)
- Snapshot cross-Region copy started (based on `SnapshotsCopiedRegionStarted`)
- Snapshot cross-Region copy completed (based on `SnapshotsCopiedRegionCompleted`)

- Snapshot cross-Region copy failed (based on `SnapshotsCopiedRegionFailed`)
- Snapshot cross-Region copy deletion completed (based on `SnapshotsCopiedRegionDeleteCompleted`)
- Snapshot cross-Region copy deletion failed (based on `SnapshotsCopiedRegionDeleteFailed`)
- Snapshot cross-account copy started (based on `SnapshotsCopiedAccountStarted`)
- Snapshot cross-account copy completed (based on `SnapshotsCopiedAccountCompleted`)
- Snapshot cross-account copy failed (based on `SnapshotsCopiedAccountFailed`)
- Snapshot cross-account copy deletion completed (based on `SnapshotsCopiedAccountDeleteCompleted`)
- Snapshot cross-account copy deletion failed (based on `SnapshotsCopiedAccountDeleteFailed`)
- AMI creation started (based on `ImagesCreateStarted`)
- AMI creation completed (based on `ImagesCreateCompleted`)
- AMI creation failed (based on `ImagesCreateFailed`)
- AMI deregistration completed (based on `ImagesDeregisterCompleted`)
- AMI deregistration failed (based on `ImagesDeregisterFailed`)
- AMI cross-Region copy started (based on `ImagesCopiedRegionStarted`)
- AMI cross-Region copy completed (based on `ImagesCopiedRegionCompleted`)
- AMI cross-Region copy failed (based on `ImagesCopiedRegionFailed`)
- AMI cross-Region copy deregistration completed (based on `ImagesCopiedRegionDeregisterCompleted`)
- AMI cross-Region copy deregister failed (based on `ImagesCopiedRegionDeregisterFailed`)
- AMI enable deprecation completed (based on `EnableImageDeprecationCompleted`)
- AMI enable deprecation failed (based on `EnableImageDeprecationFailed`)
- AMI cross-Region copy enable deprecation completed (based on `EnableCopiedImageDeprecationCompleted`)
- AMI cross-Region copy enable deprecation failed (based on `EnableCopiedImageDeprecationFailed`)

Create a CloudWatch alarm for a policy

You can create a CloudWatch alarm that monitors CloudWatch metrics for your policies. CloudWatch will automatically send you a notification when the metric reaches a threshold that you specify. You can create a CloudWatch alarm using the CloudWatch console.

For more information about creating alarms using the CloudWatch console, see the following topic in the *Amazon CloudWatch User Guide*.

- [Create a CloudWatch Alarm Based on a Static Threshold](#)
- [Create a CloudWatch Alarm Based on Anomaly Detection](#)

Example use cases

The following are example use cases.

Topics

- [Example 1: ResourcesTargeted metric \(p. 1908\)](#)
- [Example 2: SnapshotDeleteFailed metric \(p. 1908\)](#)
- [Example 3: SnapshotsCopiedRegionFailed metric \(p. 1908\)](#)

Example 1: ResourcesTargeted metric

You can use the `ResourcesTargeted` metric to monitor the total number of resources that are targeted by a specific policy each time it is run. This enables you to trigger an alarm when the number of targeted resources is below or above an expected threshold.

For example, if you expect your daily policy to create backups of no more than 50 volumes, you can create an alarm that sends an email notification when the sum for `ResourcesTargeted` is greater than 50 over a 1 hour period. In this way, you can ensure that no snapshots have been unexpectedly created from volumes that have been incorrectly tagged.

You can use the following command to create this alarm:

```
C:\> aws cloudwatch put-metric-alarm \
    --alarm-name resource-targeted-monitor \
    --alarm-description "Alarm when policy targets more than 50 resources" \
    --metric-name ResourcesTargeted \
    --namespace AWS/EBS \
    --statistic Sum \
    --period 3600 \
    --threshold 50 \
    --comparison-operator GreaterThanThreshold \
    --dimensions "Name=DLMPolicyId,Value=policy_id" \
    --evaluation-periods 1 \
    --alarm-actions sns_topic_arn
```

Example 2: SnapshotDeleteFailed metric

You can use the `SnapshotDeleteFailed` metric to monitor for failures to delete snapshots as per the policy's snapshot retention rule.

For example, if you've created a policy that should automatically delete snapshots every twelve hours, you can create an alarm that notifies your engineering team when the sum of `SnapshotDeletionFailed` is greater than 0 over a 1 hour period. This could help to investigate improper snapshot retention and to ensure that your storage costs are not increased by unnecessary snapshots.

You can use the following command to create this alarm:

```
C:\> aws cloudwatch put-metric-alarm \
    --alarm-name snapshot-deletion-failed-monitor \
    --alarm-description "Alarm when snapshot deletions fail" \
    --metric-name SnapshotsDeleteFailed \
    --namespace AWS/EBS \
    --statistic Sum \
    --period 3600 \
    --threshold 0 \
    --comparison-operator GreaterThanThreshold \
    --dimensions "Name=DLMPolicyId,Value=policy_id" \
    --evaluation-periods 1 \
    --alarm-actions sns_topic_arn
```

Example 3: SnapshotsCopiedRegionFailed metric

Use the `SnapshotsCopiedRegionFailed` metric to identify when your policies fail to copy snapshots to other Regions.

For example, if your policy copies snapshots across Regions daily, you can create an alarm that sends an SMS to your engineering team when the sum of `SnapshotCrossRegionCopyFailed` is greater than 0 over a 1 hour period. This can be useful for verifying whether subsequent snapshots in the lineage were successfully copied by the policy.

You can use the following command to create this alarm:

```
C:\> aws cloudwatch put-metric-alarm \
    --alarm-name snapshot-copy-region-failed-monitor \
    --alarm-description "Alarm when snapshot copy fails" \
    --metric-name SnapshotsCopiedRegionFailed \
    --namespace AWS/EBS \
    --statistic Sum \
    --period 3600 \
    --threshold 0 \
    --comparison-operator GreaterThanThreshold \
    --dimensions "Name=DLMPolicyId,Value=policy_id" \
    --evaluation-periods 1 \
    --alarm-actions sns_topic_arn
```

Managing policies that report failed actions

For more information about what to do when one of your policies reports an unexpected non-zero value for a failed action metric, see the [What should I do if Amazon Data Lifecycle Manager reports failed actions in CloudWatch metrics? AWS Knowledge Center article](#).

Amazon EBS data services

Amazon EBS provides the following data services.

Data services

- [Amazon EBS Elastic Volumes \(p. 1909\)](#)
- [Amazon EBS encryption \(p. 1921\)](#)
- [Amazon EBS fast snapshot restore \(p. 1934\)](#)

Amazon EBS Elastic Volumes

With Amazon EBS Elastic Volumes, you can increase the volume size, change the volume type, or adjust the performance of your EBS volumes. If your instance supports Elastic Volumes, you can do so without detaching the volume or restarting the instance. This enables you to continue using your application while the changes take effect.

There is no charge to modify the configuration of a volume. You are charged for the new volume configuration after volume modification starts. For more information, see the [Amazon EBS Pricing](#) page.

Contents

- [Requirements when modifying volumes \(p. 1909\)](#)
- [Request modifications to your EBS volumes \(p. 1911\)](#)
- [Monitor the progress of volume modifications \(p. 1914\)](#)
- [Extend a Windows file system after resizing a volume \(p. 1917\)](#)

Requirements when modifying volumes

The following requirements and limitations apply when you modify an Amazon EBS volume. To learn more about the general requirements for EBS volumes, see [Constraints on the size and configuration of an EBS volume \(p. 1724\)](#).

Topics

- [Supported instance types \(p. 1910\)](#)

- [Requirements for Windows volumes \(p. 1910\)](#)
- [Limitations \(p. 1910\)](#)

Supported instance types

Elastic Volumes are supported on the following instances:

- All [current-generation instances \(p. 212\)](#)
- The following previous-generation instances: C1, C3, G2, I2, M1, M3, and R3

If your instance type does not support Elastic Volumes, see [Modify an EBS volume if Elastic Volumes is not supported \(p. 1914\)](#).

Requirements for Windows volumes

By default, Windows initializes volumes with a Master Boot Record (MBR) partition table. Because MBR supports only volumes smaller than 2 TiB (2,048 GiB), Windows prevents you from resizing MBR volumes beyond this limit. In such a case, the **Extend Volume** option is disabled in the Windows **Disk Management** utility. If you use the AWS Management Console or AWS CLI to create an MBR-partitioned volume that exceeds the size limit, Windows cannot detect or use the additional space. For requirements affecting Linux volumes, see [Requirements for Linux volumes](#) in the *Amazon EC2 User Guide for Linux Instances*.

To overcome this limitation, you can create a new, larger volume with a GUID partition table (GPT) and copy over the data from the original MBR volume.

To create a GPT volume

1. Create a new, empty volume of the desired size in the Availability Zone of the EC2 instance and attach it to your instance.

Note

The new volume must not be a volume restored from a snapshot.

2. Log in to your Windows system and open **Disk Management** (`diskmgmt.exe`).
3. Open the context (right-click) menu for the new disk and choose **Online**.
4. In the **Initialize Disk** window, select the new disk and choose **GPT (GUID Partition Table)**, **OK**.
5. When initialization is complete, copy the data from the original volume to the new volume, using a tool such as robocopy or teracopy.
6. In **Disk Management**, change the drive letters to appropriate values and take the old volume offline.
7. In the Amazon EC2 console, detach the old volume from the instance, reboot the instance to verify that it functions properly, and delete the old volume.

Limitations

- There are limits to the maximum aggregated storage that can be requested across volume modifications. For more information, see [Amazon EBS service quotas](#) in the *Amazon Web Services General Reference*.
- After modifying a volume, you must wait at least six hours and ensure that the volume is in the in-use or available state before you can modify the same volume. This is sometimes referred to as a cooldown period.
- If the volume was attached before November 3, 2016 23:40 UTC, you must initialize Elastic Volumes support. For more information, see [Initializing Elastic Volumes Support \(p. 1913\)](#).
- If you encounter an error message while attempting to modify an EBS volume, or if you are modifying an EBS volume attached to a previous-generation instance type, take one of the following steps:

- For a non-root volume, detach the volume from the instance, apply the modifications, and then re-attach the volume.
- For a root volume, stop the instance, apply the modifications, and then restart the instance.
- Modification time is increased for volumes that are not fully initialized. For more information see [Initialize Amazon EBS volumes \(p. 1970\)](#).
- The new volume size can't exceed the supported capacity of its file system and partitioning scheme. For more information, see [Constraints on the size and configuration of an EBS volume \(p. 1724\)](#).
- If you modify the volume type of a volume, the size and performance must be within the limits of the target volume type. For more information, see [Amazon EBS volume types \(p. 1707\)](#)
- You can't decrease the size of an EBS volume. However, you can create a smaller volume and then migrate your data to it using an application-level tool such as robocopy.
- After provisioning over 32,000 IOPS on an existing io1 or io2 volume, you might need to detach and re-attach the volume, or restart the instance to see the full performance improvements.
- For io2 volumes, you can't increase the size beyond 16 TiB or the IOPS beyond 64,000 while the volume is attached to an instance type that does not support io2 Block Express volumes. For more information, see [io2 Block Express volumes \(p. 1715\)](#).
- You can't modify the volume type of Multi-Attach enabled io2 volumes.
- You can't modify the volume type, size, or Provisioned IOPS of Multi-Attach enabled io1 volumes.
- A root volume of type io1, io2, gp2, gp3, or standard can't be modified to an st1 or sc1 volume, even if it is detached from the instance.
- While m3.medium instances fully support volume modification, m3.large, m3.xlarge, and m3.2xlarge instances might not support all volume modification features.

Request modifications to your EBS volumes

With Elastic Volumes, you can dynamically increase the size, increase or decrease the performance, and change the volume type of your Amazon EBS volumes without detaching them.

Use the following process when modifying a volume:

1. (Optional) Before modifying a volume that contains valuable data, it is a best practice to create a snapshot of the volume in case you need to roll back your changes. For more information, see [Create Amazon EBS snapshots \(p. 1762\)](#).
2. Request the volume modification.
3. Monitor the progress of the volume modification. For more information, see [Monitor the progress of volume modifications \(p. 1914\)](#).
4. If the size of the volume was modified, extend the volume's file system to take advantage of the increased storage capacity. For more information, see [Extend a Windows file system after resizing a volume \(p. 1917\)](#).

Contents

- [Modify an EBS volume using Elastic Volumes \(p. 1911\)](#)
- [Initialize Elastic Volumes support \(if needed\) \(p. 1913\)](#)
- [Modify an EBS volume if Elastic Volumes is not supported \(p. 1914\)](#)

Modify an EBS volume using Elastic Volumes

Considerations

Keep the following in mind when modifying volumes:

- You can't cancel a volume modification request after it has been submitted.
- You can only increase volume size. You can't decrease volume size.
- You can increase or decrease volume performance.
- If you are not changing the volume type, then volume size and performance modifications must be within the limits of the current volume type. If you are changing the volume type, then volume size and performance modifications must be within the limits of the target volume type
- If you change the volume type from gp2 to gp3, and you do not specify IOPS or throughput performance, Amazon EBS automatically provisions either equivalent performance to that of the source gp2 volume, or the baseline gp3 performance, whichever is higher.

For example, if you modify a 500 GiB gp2 volume with 250 MiB/s throughput and 1500 IOPS to gp3 without specifying IOPS or throughput performance, Amazon EBS automatically provisions the gp3 volume with 3000 IOPS (baseline gp3 IOPS) and 250 MiB/s (to match the source gp2 volume throughput).

To modify an EBS volume, use one of the following methods.

Console

To modify an EBS volume using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Volumes**.
3. Select the volume to modify and choose **Actions, Modify volume**.
4. The **Modify volume** screen displays the volume ID and the volume's current configuration, including type, size, IOPS, and throughput. Set new configuration values as follows:
 - To modify the type, choose a value for **Volume type**.
 - To modify the size, enter a new value for **Size**.
 - (gp3, io1, and io2 only) To modify the IOPS, enter a new value for **IOPS**.
 - (gp3 only) To modify the throughput, enter a new value for **Throughput**.
5. After you have finished changing the volume settings, choose **Modify**. When prompted for confirmation, choose **Modify**.
6. **Important**
If you've increased the size of your volume, then you must also extend the volume's partition to make use of the additional storage capacity. For more information, see [Extend a Windows file system after resizing a volume \(p. 1917\)](#).
7. If you increase the size of an NVMe volume on an instance that does not have the AWS NVMe drivers, you must reboot the instance to enable Windows to see the new volume size. For more information about installing the AWS NVMe drivers, see [AWS NVMe drivers for Windows instances \(p. 799\)](#).

AWS CLI

To modify an EBS volume using the AWS CLI

Use the [modify-volume](#) command to modify one or more configuration settings for a volume. For example, if you have a volume of type gp2 with a size of 100 GiB, the following command changes its configuration to a volume of type io1 with 10,000 IOPS and a size of 200 GiB.

```
aws ec2 modify-volume --volume-type io1 --iops 10000 --size 200 --volume-id vol-1111111111111111
```

The following is example output:

```
{  
    "VolumeModification": {  
        "TargetSize": 200,  
        "TargetVolumeType": "io1",  
        "ModificationState": "modifying",  
        "VolumeId": "vol-1111111111111111",  
        "TargetIops": 10000,  
        "StartTime": "2017-01-19T22:21:02.959Z",  
        "Progress": 0,  
        "OriginalVolumeType": "gp2",  
        "OriginalIops": 300,  
        "OriginalSize": 100  
    }  
}
```

Important

If you've increased the size of your volume, then you must also extend the volume's partition to make use of the additional storage capacity. For more information, see [Extend a Windows file system after resizing a volume \(p. 1917\)](#).

Initialize Elastic Volumes support (if needed)

Before you can modify a volume that was attached to an instance before November 3, 2016 23:40 UTC, you must initialize volume modification support using one of the following actions:

- Detach and attach the volume
- Stop and start the instance

Use one of the following procedures to determine whether your instances are ready for volume modification.

Console

To determine whether your instances are ready using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation pane, choose **Instances**.
3. Choose the **Show/Hide Columns** icon (the gear). Select the **Launch time** attribute column and then choose **Confirm**.
4. Sort the list of instances by the **Launch Time** column. For each instance that was started before the cutoff date, choose the **Storage** tab and check the **Attachment time** column to see when its volumes were attached.

AWS CLI

To determine whether your instances are ready using the CLI

Use the following [describe-instances](#) command to determine whether the volume was attached before November 3, 2016 23:40 UTC.

```
aws ec2 describe-instances --query "Reservations[*].Instances[*].  
[InstanceId,LaunchTime<='2016-11-01',BlockDeviceMappings[*]  
[Ebs.AttachTime<='2016-11-01']]" --output text
```

The first line of the output for each instance shows its ID and whether it was started before the cutoff date (True or False). The first line is followed by one or more lines that show whether each EBS volume was attached before the cutoff date (True or False). In the following example output, you must initialize volume modification for the first instance because it was started before the cutoff date and its root volume was attached before the cutoff date. The other instances are ready because they were started after the cutoff date.

i-e905622e	True
True	
i-719f99a8	False
True	
i-006b02c1b78381e57	False
False	
False	
i-e3d172ed	False
True	

Modify an EBS volume if Elastic Volumes is not supported

If you are using a supported instance type, you can use Elastic Volumes to dynamically modify the size, performance, and volume type of your Amazon EBS volumes without detaching them.

If you cannot use Elastic Volumes but you need to modify the root (boot) volume, you must stop the instance, modify the volume, and then restart the instance.

After the instance has started, you can check the file system size to see if your instance recognizes the larger volume space.

If the size does not reflect your newly expanded volume, you must extend the file system of your device so that your instance can use the new space. For more information, see [Extend a Windows file system after resizing a volume \(p. 1917\)](#).

You may have to bring the volume online in order to use it. For more information, see [Make an Amazon EBS volume available for use on Windows \(p. 1731\)](#). You do not need to reformat the volume.

Monitor the progress of volume modifications

When you modify an EBS volume, it goes through a sequence of states. The volume enters the modifying state, the optimizing state, and finally the completed state. At this point, the volume is ready to be further modified.

Note

Rarely, a transient AWS fault can result in a failed state. This is not an indication of volume health; it merely indicates that the modification to the volume failed. If this occurs, retry the volume modification.

While the volume is in the optimizing state, your volume performance is in between the source and target configuration specifications. Transitional volume performance will be no less than the source volume performance. If you are downgrading IOPS, transitional volume performance is no less than the target volume performance.

Volume modification changes take effect as follows:

- Size changes usually take a few seconds to complete and take effect after the volume has transitioned to the Optimizing state.
- Performance (IOPS) changes can take from a few minutes to a few hours to complete and are dependent on the configuration change being made.

- In some cases, it can take more than 24 hours for a new configuration to take effect, such as when the volume has not been fully initialized. Typically, a fully used 1-TiB volume takes about 6 hours to migrate to a new performance configuration.

To monitor the progress of a volume modification, use one of the following methods.

Console

To monitor progress of a modification using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Volumes**.
3. Select the volume.
4. The **Volume state** column and the **Volume state** field in the **Details** tab contain information in the following format: *volume-state - modification-state (progress%)*. The following image shows the volume and volume modification states.

The screenshot shows the 'Volumes' page in the Amazon EC2 console. A blue header bar indicates a 'Requested volume modification for volume vol-0fcfb873b. The volume is being modified.' Below this, a table lists a single volume:

Name	Volume ID	Type	Size	IOPS	Volume state	Modification state
-	vol-0fcfb873b	gp2	500 GiB	1500	Available	optimizing (99%)

The possible volume states are creating, available, in-use, deleting, deleted, and error.

The possible modification states are modifying, optimizing, and completed.

After the modification completes, only the volume state is displayed. The modification state and progress are no longer displayed.

AWS CLI

To monitor progress of a modification using the AWS CLI

Use the [describe-volumes-modifications](#) command to view the progress of one or more volume modifications. The following example describes the volume modifications for two volumes.

```
aws ec2 describe-volumes-modifications --volume-ids vol-1111111111111111 vol-2222222222222222
```

In the following example output, the volume modifications are still in the modifying state. Progress is reported as a percentage.

```
{  
    "VolumesModifications": [  
        {  
            "TargetSize": 200,  
            "TargetVolumeType": "io1",  
            "ModificationState": "modifying",  
            "VolumeId": "vol-1111111111111111",  
            "TargetIops": 10000,  
            "StartTime": "2017-01-19T22:21:02.959Z",  
            "Progress": 99  
        }  
    ]  
}
```

```
        "Progress": 0,
        "OriginalVolumeType": "gp2",
        "OriginalIops": 300,
        "OriginalSize": 100
    },
    {
        "TargetSize": 2000,
        "TargetVolumeType": "sc1",
        "ModificationState": "modifying",
        "VolumeId": "vol-2222222222222222",
        "StartTime": "2017-01-19T22:23:22.158Z",
        "Progress": 0,
        "OriginalVolumeType": "gp2",
        "OriginalIops": 300,
        "OriginalSize": 1000
    }
]
```

The next example describes all volumes with a modification state of either optimizing or completed, and then filters and formats the results to show only modifications that were initiated on or after February 1, 2017:

```
aws ec2 describe-volumes-modifications --filters Name=modification-
state,Values="optimizing","completed" --query "VolumesModifications[?
StartTime>='2017-02-01'].{ID:VolumeId,STATE:ModificationState}"
```

The following is example output with information about two volumes:

```
[{
    {
        "STATE": "optimizing",
        "ID": "vol-06397e7a0eEXAMPLE"
    },
    {
        "STATE": "completed",
        "ID": "vol-ba74e18c2aEXAMPLE"
    }
]
```

CloudWatch Events console

With CloudWatch Events, you can create a notification rule for volume modification events. You can use your rule to generate a notification message using [Amazon SNS](#) or to invoke a [Lambda function](#) in response to matching events. Events are emitted on a best effort basis.

To monitor progress of a modification using CloudWatch Events

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Choose **Events, Create rule**.
3. For **Build event pattern to match events by service**, choose **Custom event pattern**.
4. For **Build custom event pattern**, replace the contents with the following and choose **Save**.

```
{
    "source": [
        "aws.ec2"
    ],
    "detail-type": [
```

```
        "EBS Volume Notification"
    ],
    "detail": {
        "event": [
            "modifyVolume"
        ]
    }
}
```

The following is example event data:

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Volume Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "2017-01-12T21:09:07Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:012345678901:volume/vol-03a55cf56513fa1b6"
    ],
    "detail": {
        "result": "optimizing",
        "cause": "",
        "event": "modifyVolume",
        "request-id": "01234567-0123-0123-0123-0123456789ab"
    }
}
```

Extend a Windows file system after resizing a volume

After you increase the size of an EBS volume, use the Windows Disk Management utility or PowerShell to extend the disk size to the new size of the volume. You can begin resizing the file system as soon as the volume enters the optimizing state. For more information about this utility, see [Extend a basic volume](#) on the Microsoft Docs website.

For more information about extending a file system on Linux, see [Extend a Linux file system after resizing a volume](#) in the *Amazon EC2 User Guide for Linux Instances*.

Contents

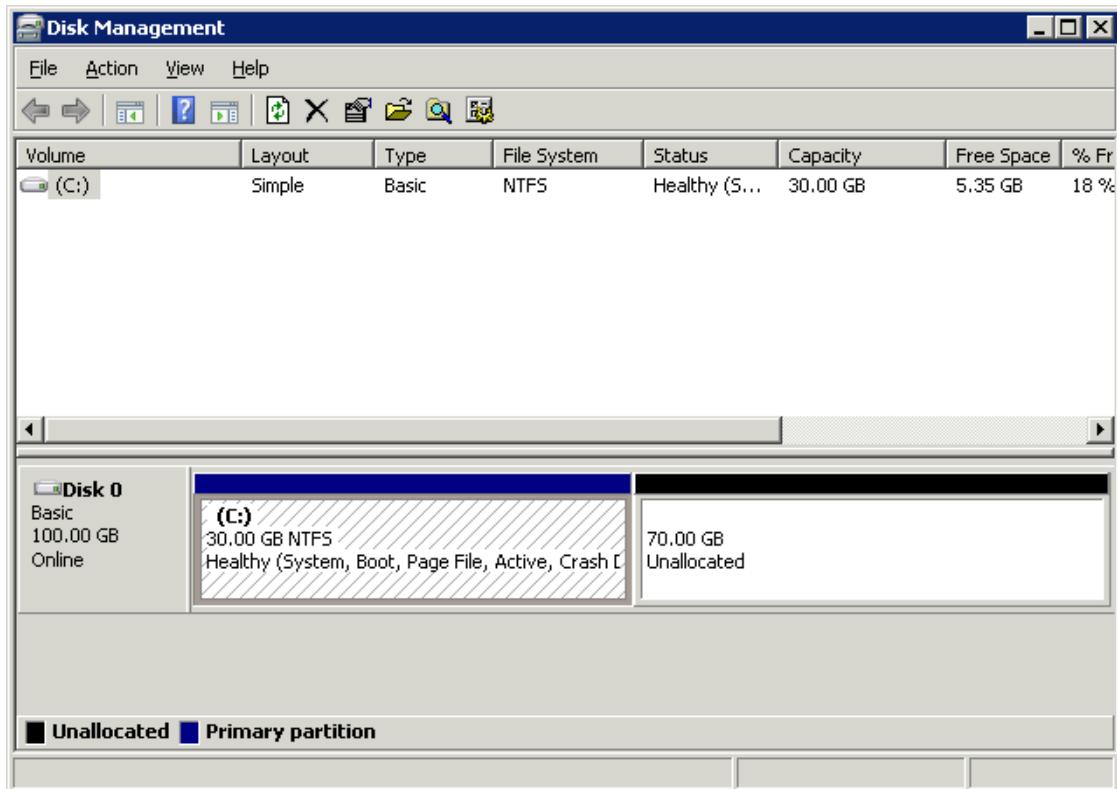

- [Extend a Windows file system using the Disk Management utility \(p. 1917\)](#)
- [Extend a Windows file system using PowerShell \(p. 1919\)](#)

Extend a Windows file system using the Disk Management utility

Use the following procedure to extend a Windows file system using Disk Management.

To extend a file system using Disk Management

1. Before extending a file system that contains valuable data, it is a best practice to create a snapshot of the volume that contains it in case you need to roll back your changes. For more information, see [Create Amazon EBS snapshots \(p. 1762\)](#).
2. Log in to your Windows instance using Remote Desktop.
3. In the **Run** dialog, enter **diskmgmt.msc** and press Enter. The Disk Management utility opens.

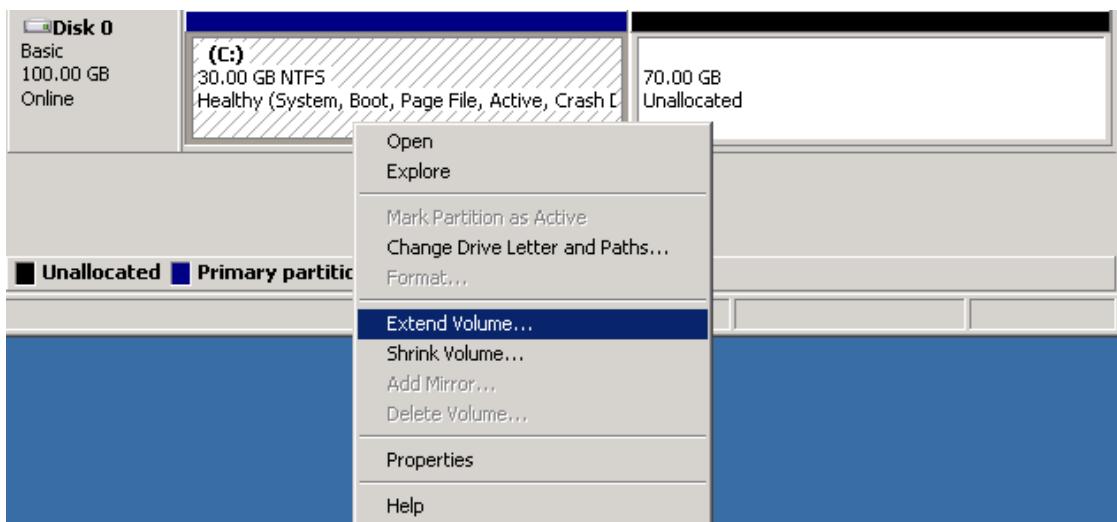

4. On the **Disk Management** menu, choose **Action**, **Rescan Disks**.
5. Open the context (right-click) menu for the expanded drive and choose **Extend Volume**.

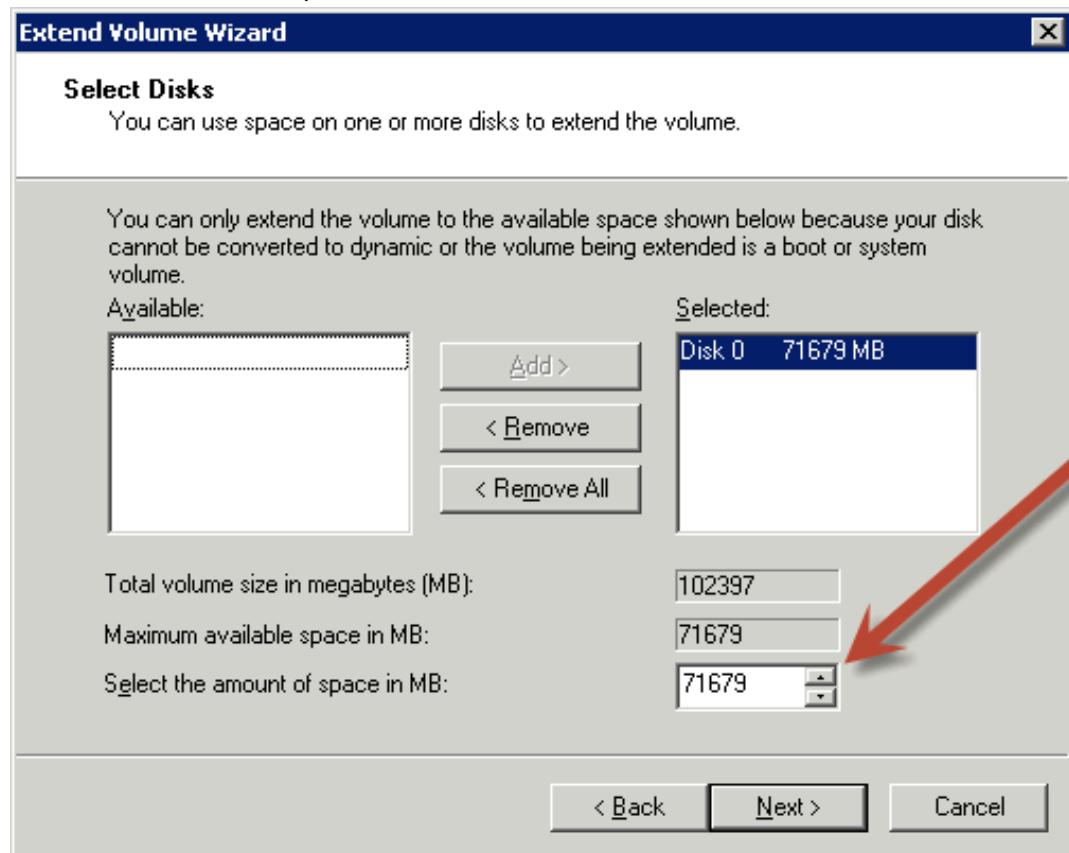

Note

Extend Volume might be disabled (grayed out) if:

- The unallocated space is not adjacent to the drive. The unallocated space must be adjacent to the right side of the drive you want to extend.
- The volume uses the Master Boot Record (MBR) partition style and it is already 2TB in size. Volumes that use MBR cannot exceed 2TB in size.

- In the **Extend Volume** wizard, choose **Next**. For **Select the amount of space in MB**, enter the number of megabytes by which to extend the volume. Generally, you specify the maximum available space. The highlighted text under **Selected** is the amount of space that is added, not the final size the volume will have. Complete the wizard.

- If you increase the size of an NVMe volume on an instance that does not have the AWS NVMe driver, you must reboot the instance to enable Windows to see the new volume size. For more information about installing the AWS NVMe driver, see [AWS NVMe drivers for Windows instances \(p. 799\)](#).

Extend a Windows file system using PowerShell

Use the following procedure to extend a Windows file system using PowerShell.

To extend a file system using PowerShell

- Before extending a file system that contains valuable data, it is a best practice to create a snapshot of the volume that contains it in case you need to roll back your changes. For more information, see [Create Amazon EBS snapshots \(p. 1762\)](#).
- Log in to your Windows instance using Remote Desktop.
- Run PowerShell as an administrator.
- Run the Get-Partition command. PowerShell returns the corresponding partition number for each partition, the drive letter, offset, size, and type. Note the drive letter of the partition to extend.
- Run the following command to rescan the disk.

```
"rescan" | diskpart
```

6. Run the following command, using the drive letter you noted in step 4 in place of <drive-letter>. PowerShell returns the minimum and maximum size of the partition allowed, in bytes.

```
Get-PartitionSupportedSize -DriveLetter <drive-letter>
```

7. To extend the partition to a specified amount, run the following command, entering the new size of the volume in place of <size>. You can enter the size in KB, MB, and GB; for example, 50GB.

```
Resize-Partition -DriveLetter <drive-letter> -Size <size>
```

To extend the partition to the maximum available size, run the following command.

```
Resize-Partition -DriveLetter <drive-letter> -Size $(Get-PartitionSupportedSize -DriveLetter <drive-letter>).SizeMax
```

The following PowerShell commands show the complete command and response flow for extending a file system to a specific size.

```
PS C:\> Get-Partition

Amazon EBS encryption

Use Amazon EBS encryption as a straight-forward encryption solution for your EBS resources associated with your EC2 instances. With Amazon EBS encryption, you aren't required to build, maintain, and secure your own key management infrastructure. Amazon EBS encryption uses AWS KMS keys when creating encrypted volumes and snapshots.

Encryption operations occur on the servers that host EC2 instances, ensuring the security of both data-at-rest and data-in-transit between an instance and its attached EBS storage.

You can attach both encrypted and unencrypted volumes to an instance simultaneously.

Contents

- [How EBS encryption works \(p. 1922\)](#)
- [Requirements \(p. 1923\)](#)
- [Default KMS key for EBS encryption \(p. 1924\)](#)
- [Encryption by default \(p. 1925\)](#)
- [Encrypt EBS resources \(p. 1927\)](#)
- [Rotating AWS KMS keys \(p. 1928\)](#)

- [Encryption scenarios \(p. 1929\)](#)
- [Set encryption defaults using the API and CLI \(p. 1934\)](#)

How EBS encryption works

You can encrypt both the boot and data volumes of an EC2 instance.

When you create an encrypted EBS volume and attach it to a supported instance type, the following types of data are encrypted:

- Data at rest inside the volume
- All data moving between the volume and the instance
- All snapshots created from the volume
- All volumes created from those snapshots

Amazon EBS encrypts your volume with a data key using industry-standard AES-256 data encryption. The data key is generated by AWS KMS and then encrypted by AWS KMS with your AWS KMS key prior to being stored with your volume information. All snapshots, and any subsequent volumes created from those snapshots using the same AWS KMS key share the same data key. For more information, see [Data keys](#) in the *AWS Key Management Service Developer Guide*.

When a KMS key becomes unusable, the effect is almost immediate (subject to eventual consistency). The key state of the KMS key changes to reflect its new condition, and all requests to use the KMS key in cryptographic operations fail. For more information, see [How unusable KMS keys affect data keys](#) in the AWS Key Management Service Developer Guide.

Amazon EC2 works with AWS KMS to encrypt and decrypt your EBS volumes in slightly different ways depending on whether the snapshot from which you create an encrypted volume is encrypted or unencrypted.

How EBS encryption works when the snapshot is encrypted

When you create an encrypted volume from an encrypted snapshot that you own, Amazon EC2 works with AWS KMS to encrypt and decrypt your EBS volumes as follows:

1. Amazon EC2 sends a [GenerateDataKeyWithoutPlaintext](#) request to AWS KMS, specifying the KMS key that you chose for volume encryption.
2. If the volume is encrypted using the same KMS key as the snapshot, AWS KMS uses the same data key as the snapshot and encrypts it under that same KMS key. If the volume is encrypted using a different KMS key, AWS KMS generates a new data key and encrypts it under the KMS key that you specified. The encrypted data key is sent to Amazon EBS to be stored with the volume metadata.
3. When you attach the encrypted volume to an instance, Amazon EC2 sends a [CreateGrant](#) request to AWS KMS so that it can decrypt the data key.
4. AWS KMS decrypts the encrypted data key and sends the decrypted data key to Amazon EC2.
5. Amazon EC2 uses the plaintext data key in the Nitro hardware to encrypt disk I/O to the volume. The plaintext data key persists in memory as long as the volume is attached to the instance.

How EBS encryption works when the snapshot is unencrypted

When you create an encrypted volume from unencrypted snapshot, Amazon EC2 works with AWS KMS to encrypt and decrypt your EBS volumes as follows:

1. Amazon EC2 sends a [CreateGrant](#) request to AWS KMS, so that it can encrypt the volume that is created from the snapshot.

2. Amazon EC2 sends a [GenerateDataKeyWithoutPlaintext](#) request to AWS KMS, specifying the KMS key that you chose for volume encryption.
3. AWS KMS generates a new data key, encrypts it under the KMS key that you chose for volume encryption, and sends the encrypted data key to Amazon EBS to be stored with the volume metadata.
4. Amazon EC2 sends a [Decrypt](#) request to AWS KMS to get the encryption key to encrypt the volume data.
5. When you attach the encrypted volume to an instance, Amazon EC2 sends a [CreateGrant](#) request to AWS KMS, so that it can decrypt the data key.
6. When you attach the encrypted volume to an instance, Amazon EC2 sends a [Decrypt](#) request to AWS KMS, specifying the encrypted data key.
7. AWS KMS decrypts the encrypted data key and sends the decrypted data key to Amazon EC2.
8. Amazon EC2 uses the plaintext data key in the Nitro hardware to encrypt disk I/O to the volume. The plaintext data key persists in memory as long as the volume is attached to the instance.

For more information, see [How Amazon Elastic Block Store \(Amazon EBS\) uses AWS KMS](#) and [Amazon EC2 example two](#) in the *AWS Key Management Service Developer Guide*.

Requirements

Before you begin, verify that the following requirements are met.

Supported volume types

Encryption is supported by all EBS volume types. You can expect the same IOPS performance on encrypted volumes as on unencrypted volumes, with a minimal effect on latency. You can access encrypted volumes the same way that you access unencrypted volumes. Encryption and decryption are handled transparently, and they require no additional action from you or your applications.

Supported instance types

Amazon EBS encryption is available on all [current generation \(p. 212\)](#) and [previous generation \(p. 217\)](#) instance types.

Permissions for users

When you configure a KMS key as the default key for EBS encryption, the default KMS key policy allows any user with access to the required KMS actions to use this KMS key to encrypt or decrypt EBS resources. You must grant users permission to call the following actions in order to use EBS encryption:

- kms:CreateGrant
- kms:Decrypt
- kms:DescribeKey
- kms:GenerateDataKeyWithoutPlainText
- kms:ReEncrypt

Tip

To follow the principle of least privilege, do not allow full access to kms:CreateGrant. Instead, use the kms:GrantIsForAWSResource condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

{

```
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Action": "kms>CreateGrant",
        "Resource": [
            "arn:aws:kms:us-east-2:123456789012:key/abcd1234-a123-456d-a12b-
a123b4cd56ef"
        ],
        "Condition": {
            "Bool": {
                "kms:GrantIsForAWSResource": true
            }
        }
    }
]
```

For more information, see [Allows access to the AWS account and enables IAM policies](#) in the **Default key policy** section in the *AWS Key Management Service Developer Guide*.

Permissions for instances

When an instance attempts to interact with an encrypted AMI, volume, or snapshot, a KMS key grant is issued to the instance's identity-only role. The identity-only role is an IAM role that is used by the instance to interact with encrypted AMIs, volumes, or snapshots on your behalf.

Identity-only roles do not need to be manually created or deleted, and they have no policies associated with them. Additionally, you can't access the identity-only role credentials.

Note

Identity-only roles are not used by applications on your instance to access other AWS KMS encrypted resources, such as Amazon S3 objects or Dynamo DB tables. These operations are done using the credentials of an Amazon EC2 instance role, or other AWS credentials that you have configured on your instance.

Identity-only roles are subject to [service control policies](#) (SCPs), and [KMS key policies](#). If an SCP or KMS key denies the identity-only role access to a KMS key, you may fail to launch EC2 instances with encrypted volumes, or using encrypted AMIs or snapshots.

If you are creating an SCP or key policy that denies access based on network location using the `aws:SourceIp`, `aws:VpcSourceIp`, `aws:SourceVpc`, or `aws:SourceVpce` AWS global condition keys, then you must ensure that these policy statements do not apply to instance-only roles. For example policies, see [Data Perimeter Policy Examples](#).

Identity-only role ARNs use the following format:

```
arn:aws-partition:iam::account_id:role/aws:ec2-infrastructure/instance_id
```

When a key grant is issued to an instance, the key grant is issued to the assumed-role session specific to that instance. The grantee principal ARN uses the following format:

```
arn:aws-partition:sts::account_id:assumed-role/aws:ec2-infrastructure/instance_id
```

Default KMS key for EBS encryption

Amazon EBS automatically creates a unique AWS managed key in each Region where you store AWS resources. This KMS key has the alias `alias/aws/ebs`. By default, Amazon EBS uses this KMS key for

encryption. Alternatively, you can specify a symmetric customer managed encryption key that you created as the default KMS key for EBS encryption. Using your own KMS key gives you more flexibility, including the ability to create, rotate, and disable KMS keys.

Important

Amazon EBS does not support asymmetric encryption KMS keys. For more information, see [Using symmetric and asymmetric encryption KMS keys](#) in the *AWS Key Management Service Developer Guide*.

New console

To configure the default KMS key for EBS encryption for a Region

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region.
3. From the navigation pane, select **EC2 Dashboard**.
4. In the upper-right corner of the page, choose **Account Attributes, EBS encryption**.
5. Choose **Manage**.
6. For **Default encryption key**, choose a symmetric customer managed encryption key.
7. Choose **Update EBS encryption**.

Old console

To configure the default KMS key for EBS encryption for a Region

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region.
3. From the navigation pane, select **EC2 Dashboard**.
4. In the upper-right corner of the page, choose **Account Attributes, Settings**.
5. Choose **Change the default key** and then choose an available KMS key.
6. Choose **Save settings**.

Encryption by default

You can configure your AWS account to enforce the encryption of the new EBS volumes and snapshot copies that you create. For example, Amazon EBS encrypts the EBS volumes created when you launch an instance and the snapshots that you copy from an unencrypted snapshot. For examples of transitioning from unencrypted to encrypted EBS resources, see [Encrypt unencrypted resources \(p. 1928\)](#).

Encryption by default has no effect on existing EBS volumes or snapshots.

Considerations

- Encryption by default is a Region-specific setting. If you enable it for a Region, you cannot disable it for individual volumes or snapshots in that Region.
- Amazon EBS encryption by default is supported on all [current generation \(p. 212\)](#) and [previous generation \(p. 217\)](#) instance types.
- If you copy a snapshot and encrypt it to a new KMS key, a complete (non-incremental) copy is created. This results in additional storage costs.
- When migrating servers using AWS Server Migration Service (SMS), do not turn on encryption by default. If encryption by default is already on and you are experiencing delta replication failures, turn off encryption by default. Instead, enable AMI encryption when you create the replication job.

Amazon EC2 console

To enable encryption by default for a Region

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region.
3. From the navigation pane, select **EC2 Dashboard**.
4. In the upper-right corner of the page, choose **Account Attributes, EBS encryption**.
5. Choose **Manage**.
6. Select **Enable**. You keep the AWS managed key with the alias alias/aws/ebs created on your behalf as the default encryption key, or choose a symmetric customer managed encryption key.
7. Choose **Update EBS encryption**.

AWS CLI

To view the encryption by default setting

- For a specific Region

```
$ aws ec2 get-ebs-encryption-by-default --region region
```

- For all Regions in your account

```
$ for region in $(aws ec2 describe-regions --region us-east-1 --query "Regions[*]. [RegionName]" --output text); do default=$(aws ec2 get-ebs-encryption-by-default --region $region --query "{Encryption_By_Default:EbsEncryptionByDefault}" --output text); kms_key=$(aws ec2 get-ebs-default-kms-key-id --region $region | jq '.KmsKeyId'); echo "$region --- $default --- $kms_key"; done
```

To enable encryption by default

- For a specific Region

```
$ aws ec2 enable-ebs-encryption-by-default --region region
```

- For all Regions in your account

```
$ for region in $(aws ec2 describe-regions --region us-east-1 --query "Regions[*]. [RegionName]" --output text); do default=$(aws ec2 enable-ebs-encryption-by-default --region $region --query "{Encryption_By_Default:EbsEncryptionByDefault}" --output text); kms_key=$(aws ec2 get-ebs-default-kms-key-id --region $region | jq '.KmsKeyId'); echo "$region --- $default --- $kms_key"; done
```

To disable encryption by default

- For a specific Region

```
$ aws ec2 disable-ebs-encryption-by-default --region region
```

- For all Regions in your account

```
$ for region in $(aws ec2 describe-regions --region us-east-1 --query "Regions[*]. [RegionName]" --output text); do default=$(aws ec2 disable-ebs-encryption-by-
```

```
default --region $region --query "[Encryption_By_Default:EbsEncryptionByDefault]"  
--output text); kms_key=$(aws ec2 get-ebs-default-kms-key-id --region $region | jq  
'.KmsKeyId'); echo "$region --- $default --- $kms_key"; done
```

PowerShell

To view the encryption by default setting

- For a specific Region

```
PS C:\> Get-EC2EbsEncryptionByDefault -Region region
```

- For all Regions in your account

```
PS C:\> (Get-EC2Region).RegionName | ForEach-Object { [PSCustomObject]@{ Region  
= $_; EC2EbsEncryptionByDefault = Get-EC2EbsEncryptionByDefault -Region $_;  
EC2EbsDefaultKmsKeyId = Get-EC2EbsDefaultKmsKeyId -Region $_ } } | Format-Table -  
AutoSize
```

To enable encryption by default

- For a specific Region

```
PS C:\> Enable-EC2EbsEncryptionByDefault -Region region
```

- For all Regions in your account

```
PS C:\> (Get-EC2Region).RegionName | ForEach-Object { [PSCustomObject]@{ Region  
= $_; EC2EbsEncryptionByDefault = Enable-EC2EbsEncryptionByDefault -Region $_;  
EC2EbsDefaultKmsKeyId = Get-EC2EbsDefaultKmsKeyId -Region $_ } } | Format-Table -  
AutoSize
```

To disable encryption by default

- For a specific Region

```
PS C:\> Disable-EC2EbsEncryptionByDefault -Region region
```

- For all Regions in your account

```
PS C:\> (Get-EC2Region).RegionName | ForEach-Object { [PSCustomObject]@{ Region  
= $_; EC2EbsEncryptionByDefault = Disable-EC2EbsEncryptionByDefault -Region $_;  
EC2EbsDefaultKmsKeyId = Get-EC2EbsDefaultKmsKeyId -Region $_ } } | Format-Table -  
AutoSize
```

You cannot change the KMS key that is associated with an existing snapshot or encrypted volume. However, you can associate a different KMS key during a snapshot copy operation so that the resulting copied snapshot is encrypted by the new KMS key.

Encrypt EBS resources

You encrypt EBS volumes by enabling encryption, either using [encryption by default \(p. 1925\)](#) or by enabling encryption when you create a volume that you want to encrypt.

When you encrypt a volume, you can specify the symmetric encryption KMS key to use to encrypt the volume. If you do not specify a KMS key, the KMS key that is used for encryption depends on the encryption state of the source snapshot and its ownership. For more information, see the [encryption outcomes table \(p. 1932\)](#).

Note

If you are using the API or AWS CLI to specify a KMS key, be aware that AWS authenticates the KMS key asynchronously. If you specify a KMS key ID, an alias, or an ARN that is not valid, the action can appear to complete, but it eventually fails.

You cannot change the KMS key that is associated with an existing snapshot or volume. However, you can associate a different KMS key during a snapshot copy operation so that the resulting copied snapshot is encrypted by the new KMS key.

Encrypt an empty volume on creation

When you create a new, empty EBS volume, you can encrypt it by enabling encryption for the specific volume creation operation. If you enabled EBS encryption by default, the volume is automatically encrypted using your default KMS key for EBS encryption. Alternatively, you can specify a different symmetric encryption KMS key for the specific volume creation operation. The volume is encrypted by the time it is first available, so your data is always secured. For detailed procedures, see [Create an Amazon EBS volume \(p. 1726\)](#).

By default, the KMS key that you selected when creating a volume encrypts the snapshots that you make from the volume and the volumes that you restore from those encrypted snapshots. You cannot remove encryption from an encrypted volume or snapshot, which means that a volume restored from an encrypted snapshot, or a copy of an encrypted snapshot, is always encrypted.

Public snapshots of encrypted volumes are not supported, but you can share an encrypted snapshot with specific accounts. For detailed directions, see [Share an Amazon EBS snapshot \(p. 1810\)](#).

Encrypt unencrypted resources

You cannot directly encrypt existing unencrypted volumes or snapshots. However, you can create encrypted volumes or snapshots from unencrypted volumes or snapshots. If you enable encryption by default, Amazon EBS automatically encrypts new volumes and snapshots using your default KMS key for EBS encryption. Otherwise, you can enable encryption when you create an individual volume or snapshot, using either the default KMS key for Amazon EBS encryption or a symmetric customer managed encryption key. For more information, see [Create an Amazon EBS volume \(p. 1726\)](#) and [Copy an Amazon EBS snapshot \(p. 1781\)](#).

To encrypt the snapshot copy to a customer managed key, you must both enable encryption and specify the KMS key, as shown in [Copy an unencrypted snapshot \(encryption by default not enabled\) \(p. 1930\)](#).

Important

Amazon EBS does not support asymmetric encryption KMS keys. For more information, see [Using Symmetric and Asymmetric encryption KMS keys](#) in the *AWS Key Management Service Developer Guide*.

You can also apply new encryption states when launching an instance from an EBS-backed AMI. This is because EBS-backed AMIs include snapshots of EBS volumes that can be encrypted as described. For more information, see [Use encryption with EBS-backed AMIs \(p. 193\)](#).

Rotating AWS KMS keys

Cryptographic best practices discourage extensive reuse of encryption keys. To create new cryptographic material for your KMS key, you can create new KMS key, and then change your applications or aliases to use the new KMS key. Or, you can enable automatic key rotation for an existing KMS key.

When you enable automatic key rotation for a KMS key, AWS KMS generates new cryptographic material for the KMS key every year. AWS KMS saves all previous versions of the cryptographic material so you

can decrypt any data encrypted with that KMS key. AWS KMS does not delete any rotated key material until you delete the KMS key.

When you use a rotated KMS key to encrypt data, AWS KMS uses the current key material. When you use the rotated KMS key to decrypt data, AWS KMS uses the version of the key material that was used to encrypt it. You can safely use a rotated KMS key in applications and AWS services without code changes.

Note

Automatic key rotation is supported only for symmetric customer managed keys with key material that AWS KMS creates. AWS KMS automatically rotates AWS managed keys every year. You can't enable or disable key rotation for AWS managed keys.

For more information, see [Rotating KMS key](#) in the *AWS Key Management Service Developer Guide*.

Encryption scenarios

When you create an encrypted EBS resource, it is encrypted by your account's default KMS key for EBS encryption unless you specify a different customer managed key in the volume creation parameters or the block device mapping for the AMI or instance. For more information, see [Default KMS key for EBS encryption \(p. 1924\)](#).

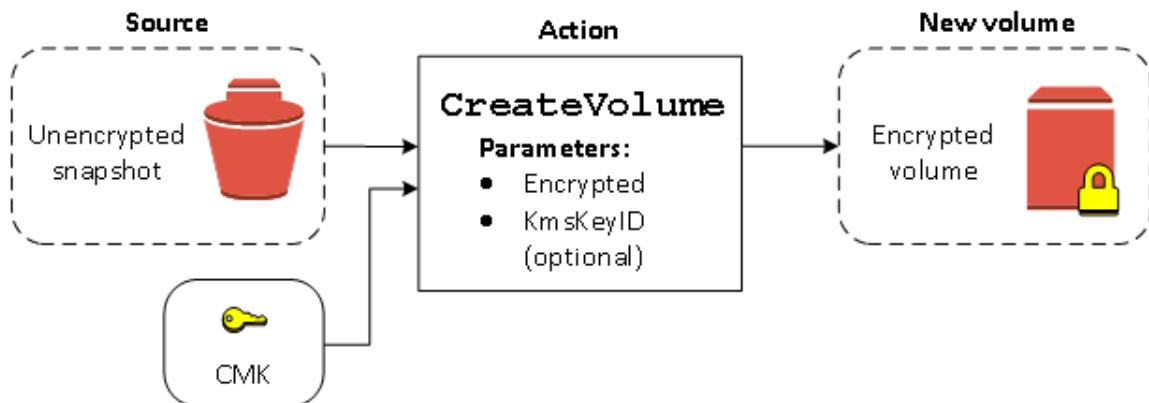

The following examples illustrate how you can manage the encryption state of your volumes and snapshots. For a full list of encryption cases, see the [encryption outcomes table \(p. 1932\)](#).

Examples

- [Restore an unencrypted volume \(encryption by default not enabled\) \(p. 1929\)](#)
- [Restore an unencrypted volume \(encryption by default enabled\) \(p. 1930\)](#)
- [Copy an unencrypted snapshot \(encryption by default not enabled\) \(p. 1930\)](#)
- [Copy an unencrypted snapshot \(encryption by default enabled\) \(p. 1930\)](#)
- [Re-encrypt an encrypted volume \(p. 1931\)](#)
- [Re-encrypt an encrypted snapshot \(p. 1931\)](#)
- [Migrate data between encrypted and unencrypted volumes \(p. 1932\)](#)
- [Encryption outcomes \(p. 1932\)](#)

Restore an unencrypted volume (encryption by default not enabled)

Without encryption by default enabled, a volume restored from an unencrypted snapshot is unencrypted by default. However, you can encrypt the resulting volume by setting the `Encrypted` parameter and, optionally, the `KmsKeyId` parameter. The following diagram illustrates the process.

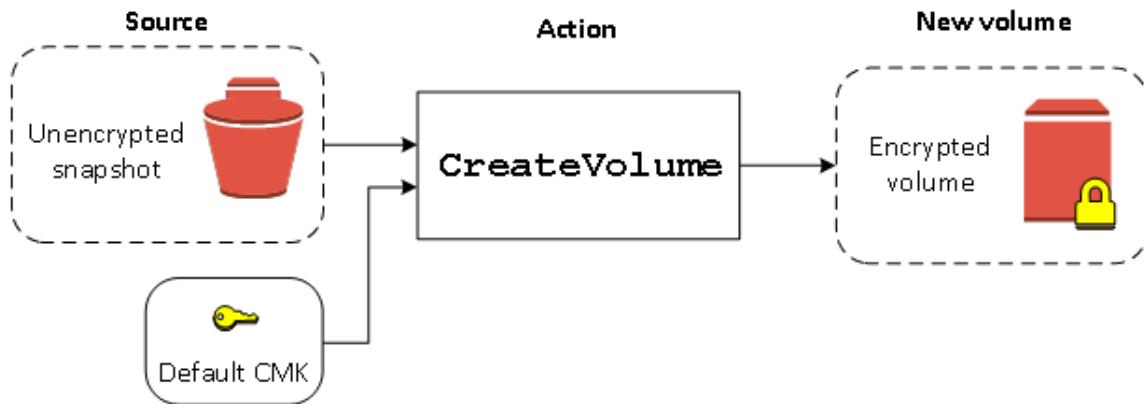

If you leave out the `KmsKeyId` parameter, the resulting volume is encrypted using your default KMS key for EBS encryption. You must specify a KMS key ID to encrypt the volume to a different KMS key.

For more information, see [Create a volume from a snapshot \(p. 1728\)](#).

Restore an unencrypted volume (encryption by default enabled)

When you have enabled encryption by default, encryption is mandatory for volumes restored from unencrypted snapshots, and no encryption parameters are required for your default KMS key to be used. The following diagram shows this simple default case:

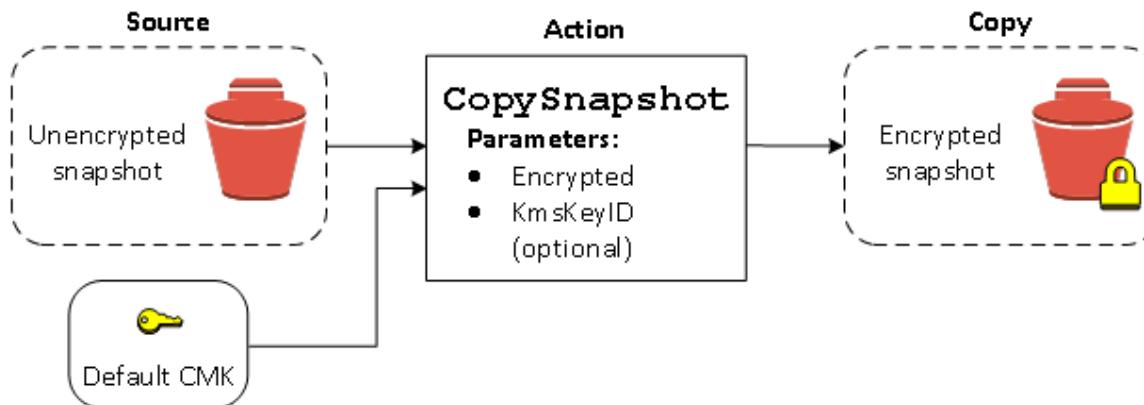

If you want to encrypt the restored volume to a symmetric customer managed encryption key, you must supply both the Encrypted and KmsKeyId parameters as shown in [Restore an unencrypted volume \(encryption by default not enabled\) \(p. 1929\)](#).

Copy an unencrypted snapshot (encryption by default not enabled)

Without encryption by default enabled, a copy of an unencrypted snapshot is unencrypted by default. However, you can encrypt the resulting snapshot by setting the Encrypted parameter and, optionally, the KmsKeyId parameter. If you omit KmsKeyId, the resulting snapshot is encrypted by your default KMS key. You must specify a KMS key ID to encrypt the volume to a different symmetric encryption KMS key.

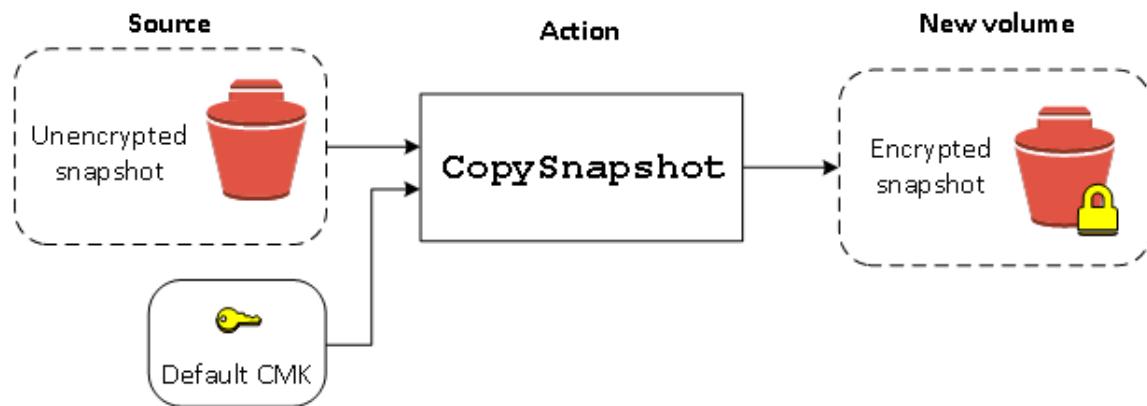

The following diagram illustrates the process.

You can encrypt an EBS volume by copying an unencrypted snapshot to an encrypted snapshot and then creating a volume from the encrypted snapshot. For more information, see [Copy an Amazon EBS snapshot \(p. 1781\)](#).

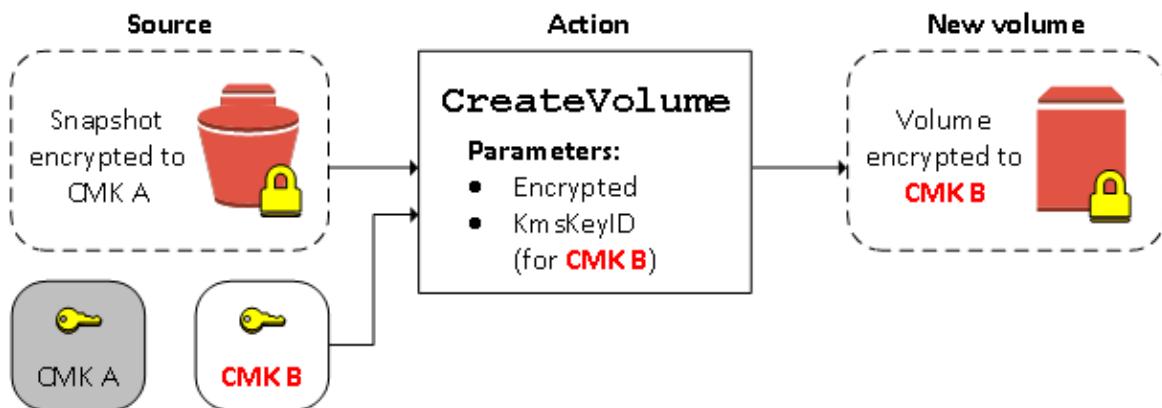

Copy an unencrypted snapshot (encryption by default enabled)

When you have enabled encryption by default, encryption is mandatory for copies of unencrypted snapshots, and no encryption parameters are required if your default KMS key is used. The following diagram illustrates this default case:

Re-encrypt an encrypted volume

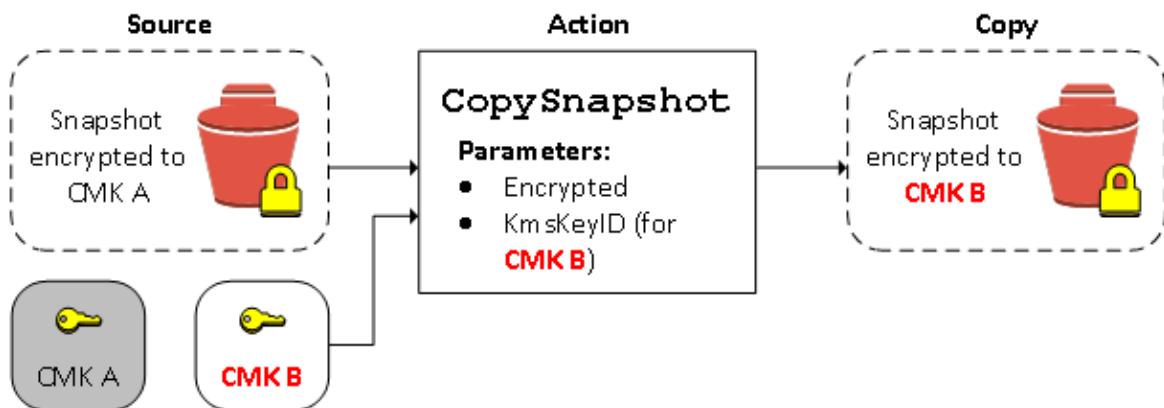

When the `CreateVolume` action operates on an encrypted snapshot, you have the option of re-encrypting it with a different KMS key. The following diagram illustrates the process. In this example, you own two KMS keys, KMS key A and KMS key B. The source snapshot is encrypted by KMS key A. During volume creation, with the KMS key ID of KMS key B specified as a parameter, the source data is automatically decrypted, then re-encrypted by KMS key B.

For more information, see [Create a volume from a snapshot \(p. 1728\)](#).

Re-encrypt an encrypted snapshot

The ability to encrypt a snapshot during copying allows you to apply a new symmetric encryption KMS key to an already-encrypted snapshot that you own. Volumes restored from the resulting copy are only accessible using the new KMS key. The following diagram illustrates the process. In this example, you own two KMS keys, KMS key A and KMS key B. The source snapshot is encrypted by KMS key A. During copy, with the KMS key ID of KMS key B specified as a parameter, the source data is automatically re-encrypted by KMS key B.

In a related scenario, you can choose to apply new encryption parameters to a copy of a snapshot that has been shared with you. By default, the copy is encrypted with a KMS key shared by the snapshot's owner. However, we recommend that you create a copy of the shared snapshot using a different KMS key that you control. This protects your access to the volume if the original KMS key is compromised, or if the owner revokes the KMS key for any reason. For more information, see [Encryption and snapshot copying \(p. 1784\)](#).

Migrate data between encrypted and unencrypted volumes

When you have access to both an encrypted and unencrypted volume, you can freely transfer data between them. EC2 carries out the encryption and decryption operations transparently.

For example, use the **robocopy** command to copy the data. In the following command, the source data is located in D:\ and the destination volume is mounted at E:\.

```
PS C:\> robocopy D:\sourcefolder E:\destinationfolder /e /copyall /eta
```

We recommend using folders rather than copying an entire volume, as this avoids potential problems with hidden folders.

Encryption outcomes

The following table describes the encryption outcome for each possible combination of settings.

Is encryption enabled?	Is encryption by default enabled?	Source of volume	Default (no customer managed key specified)	Custom (customer managed key specified)
No	No	New (empty) volume	Unencrypted	N/A
No	No	Unencrypted snapshot that you own	Unencrypted	
No	No	Encrypted snapshot that you own	Encrypted by same key	
No	No	Unencrypted snapshot that is shared with you	Unencrypted	
No	No	Encrypted snapshot that is shared with you	Encrypted by default customer managed key*	

Amazon Elastic Compute Cloud
User Guide for Windows Instances
EBS data services

Is encryption enabled?	Is encryption by default enabled?	Source of volume	Default (no customer managed key specified)	Custom (customer managed key specified)
Yes	No	New volume	Encrypted by default customer managed key	Encrypted by a specified customer managed key**
Yes	No	Unencrypted snapshot that you own	Encrypted by default customer managed key	
Yes	No	Encrypted snapshot that you own	Encrypted by same key	
Yes	No	Unencrypted snapshot that is shared with you	Encrypted by default customer managed key	
Yes	No	Encrypted snapshot that is shared with you	Encrypted by default customer managed key	
No	Yes	New (empty) volume	Encrypted by default customer managed key	N/A
No	Yes	Unencrypted snapshot that you own	Encrypted by default customer managed key	
No	Yes	Encrypted snapshot that you own	Encrypted by same key	
No	Yes	Unencrypted snapshot that is shared with you	Encrypted by default customer managed key	
No	Yes	Encrypted snapshot that is shared with you	Encrypted by default customer managed key	
Yes	Yes	New volume	Encrypted by default customer managed key	Encrypted by a specified customer managed key
Yes	Yes	Unencrypted snapshot that you own	Encrypted by default customer managed key	
Yes	Yes	Encrypted snapshot that you own	Encrypted by same key	
Yes	Yes	Unencrypted snapshot that is shared with you	Encrypted by default customer managed key	
Yes	Yes	Encrypted snapshot that is shared with you	Encrypted by default customer managed key	

* This is the default customer managed key used for EBS encryption for the AWS account and Region. By default this is a unique AWS managed key for EBS, or you can specify a customer managed key. For more information, see [Default KMS key for EBS encryption \(p. 1924\)](#).

** This is a customer managed key specified for the volume at launch time. This customer managed key is used instead of the default customer managed key for the AWS account and Region.

Set encryption defaults using the API and CLI

You can manage encryption by default and the default KMS key using the following API actions and CLI commands.

API action	CLI command	Description
DisableEbsEncryptionByDefault	disable-ebs-encryption-by-default	Disables encryption by default.
EnableEbsEncryptionByDefault	enable-ebs-encryption-by-default	Enables encryption by default.
GetEbsDefaultKmsKeyId	get-ebs-default-kms-key-id	Describes the default KMS key.
GetEbsEncryptionByDefault	get-ebs-encryption-by-default	Indicates whether encryption by default is enabled.
ModifyEbsDefaultKmsKeyId	modify-ebs-default-kms-key-id	Changes the default KMS key used to encrypt EBS volumes.
ResetEbsDefaultKmsKeyId	reset-ebs-default-kms-key-id	Resets the AWS managed key as the default KMS key used to encrypt EBS volumes.

Amazon EBS fast snapshot restore

Amazon EBS fast snapshot restore (FSR) enables you to create a volume from a snapshot that is fully initialized at creation. This eliminates the latency of I/O operations on a block when it is accessed for the first time. Volumes that are created using fast snapshot restore instantly deliver all of their provisioned performance.

To get started, enable fast snapshot restore for specific snapshots in specific Availability Zones. Each snapshot and Availability Zone pair refers to one fast snapshot restore. When you create a volume from one of these snapshots in one of its enabled Availability Zones, the volume is restored using fast snapshot restore.

Fast snapshot restore must be explicitly enabled on a per-snapshot basis. If you create a new snapshot from a volume that was restored from a fast snapshot restore-enabled snapshot, the new snapshot is not automatically enabled for fast snapshot restore. You must explicitly enable it for the new snapshot.

The number of volumes that you can restore with the full performance benefit of fast snapshot restore is determined by volume creation credits for the snapshot. For more information see [Volume creation credits \(p. 1935\)](#).

You can enable fast snapshot restore for snapshots that you own and for public and private snapshots that are shared with you.

Contents

- [Considerations \(p. 1935\)](#)
- [Volume creation credits \(p. 1935\)](#)
- [Manage fast snapshot restore \(p. 1936\)](#)
- [Monitor fast snapshot restore \(p. 1939\)](#)
- [Fast snapshot restore quotas \(p. 1939\)](#)
- [Pricing and Billing \(p. 1939\)](#)

Considerations

- Fast snapshot restore is not supported with AWS Outposts, Local Zones, and Wavelength Zones.
- Fast snapshot restore can be enabled on snapshots with a size of 16 TiB or less.
- Volumes provisioned with performance up to 64,000 IOPS and 1,000 MiB/s throughput receive the full performance benefit of fast snapshot restore. For volumes provisioned with performance greater than 64,000 IOPS or 1,000 MiB/s throughput, we recommend that you [initialize the volume \(p. 1970\)](#) to receive its full performance.

Volume creation credits

The number of volumes that receive the full performance benefit of fast snapshot restore is determined by the volume creation credits for the snapshot. There is one credit bucket per snapshot per Availability Zone. Each volume that you create from a snapshot with fast snapshot restore enabled consumes one credit from the credit bucket. You must have at least one credit in the bucket to create an initialized volume from the snapshot. If you create a volume but there is less than one credit in the bucket, the volume is created without benefit of fast snapshot restore.

When you enable fast snapshot restore for a snapshot that is shared with you, you get a separate credit bucket for the shared snapshot in your account. If you create volumes from the shared snapshot, the credits are consumed from your credit bucket; they are not consumed from the snapshot owner's credit bucket.

The size of a credit bucket and the rate at which it refills depends on the size of the snapshot, not the size of the volumes created from the snapshot.

When you enable fast snapshot restore for a snapshot, the credit bucket starts with zero credits, and it gets filled at a set rate until it reaches its maximum credit capacity. Also, as you consume credits, the credit bucket is refilled over time until it reaches its maximum credit capacity.

The fill rate for a credit bucket is calculated as follows:

```
MIN (10, (1024 ÷ snapshot_size_gib))
```

And the size of the credit bucket is calculated as follows:

```
MAX (1, MIN (10, (1024 ÷ snapshot_size_gib)))
```

For example, if you enable fast snapshot restore for a snapshot with a size of 128 GiB, the fill rate is 0.1333 credits per minute.

```
MIN (10, (1024 ÷ 128))
= MIN (10, 8)
= 8 credits per hour
```

= 0.1333 credits per minute

And the maximum size of the credit bucket is 8 credits.

```
MAX (1, MIN (10, (1024 ÷ 128)))
= MAX (1, MIN (10, 8))
= MAX (1, 8)
= 8 credits
```

In this example, when you enable fast snapshot restore, the credit bucket starts with zero credits. After 8 minutes, the credit bucket has enough credits to create one initialized volume ($0.1333 \text{ credits} \times 8 \text{ minutes} = 1.066 \text{ credits}$). When the credit bucket is full, you can create 8 initialized volumes simultaneously (8 credits). When the bucket is below its maximum capacity, it refills with 0.1333 credits per minute.

You can use Cloudwatch metrics to monitor the size of your credit buckets and the number of credits available in each bucket. For more information, see [Fast snapshot restore metrics \(p. 1984\)](#).

After you create a volume from a snapshot with fast snapshot restore enabled, you can describe the volume using [describe-volumes](#) and check the `fastRestored` field in the output to determine whether the volume was created as an initialized volume using fast snapshot restore.

Manage fast snapshot restore

Topics

- [Enable or disable fast snapshot restore \(p. 1936\)](#)
- [View the fast snapshot restore state for a snapshot \(p. 1937\)](#)
- [View volumes restored using fast snapshot restore \(p. 1938\)](#)

Enable or disable fast snapshot restore

Fast snapshot restore is disabled for a snapshot by default. You can enable or disable fast snapshot restore for snapshots that you own and for snapshots that are shared with you. When you enable or disable fast snapshot restore for a snapshot, the changes apply to your account only.

Note

When you enable fast snapshot restore for a snapshot, your account is billed for each minute that fast snapshot restore is enabled in a particular Availability Zone. Charges are pro-rated and have a minimum of one hour.

When you delete a snapshot that you own, fast snapshot restore is automatically disabled for that snapshot in your account. If you enabled fast snapshot restore for a snapshot that is shared with you, and the snapshot owner deletes or unshares it, fast snapshot restore is automatically disabled for the shared snapshot in your account.

If you enabled fast snapshot restore for a snapshot that is shared with you, and it has been encrypted using a custom CMK, fast snapshot restore is not automatically disabled for the snapshot when the snapshot owner revokes your access to the custom CMK. You must manually disable fast snapshot restore for that snapshot.

Use one of the following methods to enable or disable fast snapshot restore for a snapshot that you own or for a snapshot that is shared with you.

Console

To enable or disable fast snapshot restore

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Snapshots**.
3. Select the snapshot, and choose **Actions, Manage fast snapshot restore**.
4. The **Fast snapshot restore settings** section lists all of the Availability Zones in which you can enable fast snapshot restore for the selected snapshot. The **Current status** volume indicates whether fast snapshot restore is current enabled or disabled for each zone.

To enable fast snapshot restore in a zone where it is currently disabled, select the zone, choose **Enable**, and then to confirm, choose **Enable**.

To disable fast snapshot restore in a zone where it is currently enabled, select the zone, and then choose **Disable**.

5. After you have made the required changes, choose **Close**.

AWS CLI

To manage fast snapshot restore using the AWS CLI

- [enable-fast-snapshot-restores](#)
- [disable-fast-snapshot-restores](#)
- [describe-fast-snapshot-restores](#)

Note

After you enable fast snapshot restore for a snapshot, it enters the optimizing state. Snapshots that are in the optimizing state provide some performance benefits when using them to restore volumes. They start to provide the full performance benefits of fast snapshot restore only after they enter the enabled state.

View the fast snapshot restore state for a snapshot

Fast snapshot restore for a snapshot can be in one of the following states.

- enabling — A request was made to enable fast snapshot restore.
- optimizing — Fast snapshot restore is being enabled. It takes 60 minutes per TiB to optimize a snapshot. Snapshots in this state offer some performance benefit when restoring volumes.
- enabled — Fast snapshot restore is enabled. Snapshots in this state offer the full performance benefit when restoring volumes.
- disabling — A request was made to disable fast snapshot restore, or a request to enable fast snapshot restore failed.
- disabled — Fast snapshot restore is disabled. You can enable fast snapshot restore again as needed.

Use one of the following methods to view the state of fast snapshot restore for a snapshot that you own or for a snapshot that is shared with you.

Console

To view the state of fast snapshot restore using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the snapshot.
4. On the **Details** tab, **Fast snapshot restore**, indicates the state of fast snapshot restore.

AWS CLI

To view snapshots with fast snapshot restore enabled using the AWS CLI

Use the [describe-fast-snapshot-restores](#) command to describe the snapshots that are enabled for fast snapshot restore.

```
aws ec2 describe-fast-snapshot-restores --filters Name=state,Values=enabled
```

The following is example output.

```
{  
    "FastSnapshotRestores": [  
        {  
            "SnapshotId": "snap-0e946653493cb0447",  
            "AvailabilityZone": "us-east-2a",  
            "State": "enabled",  
            "StateTransitionReason": "Client.UserInitiated - Lifecycle state transition",  
            "OwnerId": "123456789012",  
            "EnablingTime": "2020-01-25T23:57:49.596Z",  
            "OptimizingTime": "2020-01-25T23:58:25.573Z",  
            "EnabledTime": "2020-01-25T23:59:29.852Z"  
        },  
        {  
            "SnapshotId": "snap-0e946653493cb0447",  
            "AvailabilityZone": "us-east-2b",  
            "State": "enabled",  
            "StateTransitionReason": "Client.UserInitiated - Lifecycle state transition",  
            "OwnerId": "123456789012",  
            "EnablingTime": "2020-01-25T23:57:49.596Z",  
            "OptimizingTime": "2020-01-25T23:58:25.573Z",  
            "EnabledTime": "2020-01-25T23:59:29.852Z"  
        }  
    ]  
}
```

View volumes restored using fast snapshot restore

When you create a volume from a snapshot that is enabled for fast snapshot restore in the Availability Zone for the volume, it is restored using fast snapshot restore.

Use the [describe-volumes](#) command to view volumes that were created from a snapshot that is enabled for fast snapshot restore.

```
aws ec2 describe-volumes --filters Name=fast-restored,Values=true
```

The following is example output.

```

Monitor fast snapshot restore

Amazon EBS emits Amazon CloudWatch events when the fast snapshot restore state for a snapshot changes. For more information, see [EBS fast snapshot restore events \(p. 1993\)](#).

Fast snapshot restore quotas

You can enable up to 5 snapshots for fast snapshot restore per Region. The quota applies to snapshots that you own and snapshots that are shared with you. If you enable fast snapshot restore for a snapshot that is shared with you, it counts towards your fast snapshot restore quota. It does not count towards the snapshot owner's fast snapshot restore quota.

Pricing and Billing

You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour.

For example, if you enable fast snapshot restore for one snapshot in US-East-1a for one month (30 days), you are billed **\$540** (1 snapshot x 1 AZ x 720 hours x \$0.75 per hour). If you enable fast snapshot restore for two snapshots in us-east-1a, us-east-1b, and us-east-1c for the same period, you are billed **\$3240** (2 snapshots x 3 AZs x 720 hours x \$0.75 per hour).

If you enable fast snapshot restore for a public or private snapshot that is shared with you, your account is billed; the snapshot owner is not billed. When a snapshot that is shared with you is deleted or unshared by the snapshot owner, fast snapshot restore is disabled for the snapshot in your account and billing is stopped.

For more information, see [Amazon EBS pricing](#).

Amazon EBS and NVMe on Windows instances

EBS volumes are exposed as NVMe block devices on instances built on the [Nitro System \(p. 218\)](#). When you attach a volume to your instance, you include a device name for the volume. This device name is used by Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume, and the name assigned can be different from the name that Amazon EC2 uses.

The EBS performance guarantees stated in [Amazon EBS Product Details](#) are valid regardless of the block-device interface.

For information about EBS volumes and NVME on Linux instances, see the [User Guide for Linux Instances](#).

Contents

- [Install or upgrade the NVMe driver \(p. 1940\)](#)
- [Identify the EBS device \(p. 1940\)](#)
- [Work with NVMe EBS volumes \(p. 1940\)](#)
- [I/O operation timeout \(p. 1941\)](#)

- [Abort command \(p. 1941\)](#)

Install or upgrade the NVMe driver

The AWS Windows AMIs for Windows Server 2008 R2 and later include the AWS NVMe driver. If you are not using the latest AWS Windows AMIs provided by Amazon, see [Install or upgrade AWS NVMe drivers using PowerShell \(p. 799\)](#).

Identify the EBS device

EBS uses single-root I/O virtualization (SR-IOV) to provide volume attachments on Nitro-based instances using the NVMe specification. These devices rely on standard NVMe drivers on the operating system. These drivers typically discover attached devices during instance boot, and create device nodes based on the order in which the devices respond, not on how the devices are specified in the block device mapping. Additionally, the device name assigned by the block device driver can be different from the name specified in the block device mapping.

Windows Server 2008 R2 and later

You can also run the **ebsnvme-id** command to map the NVMe device disk number to an EBS volume ID and device name. By default, all EBS NVMe devices are enumerated. You can pass a disk number to enumerate information for a specific device. Ebsnvme-id is included in the latest AWS provided Windows Server AMIs located in C:\PROGRAMDATA\AMAZON\Tools.

You can also download [ebsnvme-id.zip](#) and extract the contents to your Amazon EC2 instance to get access to ebsnvme-id.exe.

```
PS C:\Users\Administrator\Desktop> ebsnvme-id.exe
Disk Number: 0
Volume ID: vol-0d6d7ee9f6e471a7f
Device Name: sda1

Disk Number: 1
Volume ID: vol-03a26248ff39b57cf
Device Name: xvdd

Disk Number: 2
Volume ID: vol-038bd1c629aa125e6
Device Name: xvde

PS C:\Users\Administrator\Desktop> ebsnvme-id 4
Disk Number: 4
Volume ID: vol-03e2dbe464b66f0a1
Device Name: xvdc
```

Work with NVMe EBS volumes

The latest AWS Windows AMIs contain the AWS NVMe driver that is required by instance types that expose EBS volumes as NVMe block devices. However, if you resize your root volume on a Windows system, you must rescan the volume in order for this change to be reflected in the instance. If you launched your instance from a different AMI, it might not contain the required AWS NVMe driver. If your

instance does not have the latest AWS NVMe driver, you must install it. For more information, see [AWS NVMe drivers for Windows instances \(p. 799\)](#).

I/O operation timeout

Most operating systems specify a timeout for I/O operations submitted to NVMe devices. On Windows systems, the default timeout is 60 seconds and the maximum is 255 seconds. You can modify the TimeoutValue disk class registry setting using the procedure described in [Registry Entries for SCSI Miniport Drivers](#).

Abort command

The Abort command is an NVMe Admin command that is issued to abort a specific command that was previously submitted to the controller. This command is typically issued by the device driver to storage devices that have exceeded the I/O operation timeout threshold. Amazon EC2 instance types that support the Abort command by default will abort a specific command that was previously submitted to the controller of the attached Amazon EBS device to which an Abort command is issued.

The following instance types support the Abort command for all attached Amazon EBS volumes by default: R5b, R6i, M6i, M6a, C6gn, C6i, X2gd, X2iezn, Ix4gn, Is4gen.

Other instance types take no action when Abort commands are issued to attached Amazon EBS volumes.

Amazon EBS devices with NVMe device version 1.4 or higher support the Abort command.

For more information, see section [5.1 Abort command](#) of the [NVM Express Base Specification](#).

Amazon EBS–optimized instances

An Amazon EBS–optimized instance uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. This optimization provides the best performance for your EBS volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

EBS–optimized instances deliver dedicated bandwidth to Amazon EBS. When attached to an EBS–optimized instance, General Purpose SSD (gp2 and gp3) volumes are designed to deliver at least 90% of their provisioned IOPS performance 99% of the time in a given year, and Provisioned IOPS SSD (io1 and io2) volumes are designed to deliver at least 90% of their provisioned IOPS performance 99.9% of the time in a given year. Both Throughput Optimized HDD (st1) and Cold HDD (sc1) deliver at least 90% of their expected throughput performance 99% of the time in a given year. Non-compliant periods are approximately uniformly distributed, targeting 99% of expected total throughput each hour. For more information, see [Amazon EBS volume types \(p. 1707\)](#).

Important

An instance's EBS performance is bounded by the instance's performance limits, or the aggregated performance of its attached volumes, whichever is smaller. To achieve maximum EBS performance, an instance must have attached volumes that provide a combined performance equal to or greater than the maximum instance performance. For example, to achieve 80,000 IOPS for t6i.16xlarge, the instance must have at least 5 gp3 volumes provisioned with 16,000 IOPS each (5 volumes x 16,000 IOPS = 80,000 IOPS).

Contents

- [Supported instance types \(p. 1942\)](#)
- [Get maximum performance \(p. 1962\)](#)
- [View instances types that support EBS optimization \(p. 1963\)](#)
- [Enable EBS optimization at launch \(p. 1964\)](#)
- [Enable EBS optimization for an existing instance \(p. 1964\)](#)

Supported instance types

The following tables show which instance types support EBS optimization. They include the dedicated bandwidth to Amazon EBS, the typical maximum aggregate throughput that can be achieved on that connection with a streaming read workload and 128 KiB I/O size, and the maximum IOPS the instance can support if you are using a 16 KiB I/O size.

Choose an EBS–optimized instance that provides more dedicated Amazon EBS throughput than your application needs; otherwise, the connection between Amazon EBS and Amazon EC2 can become a performance bottleneck.

Topics

- [EBS optimized by default \(p. 1942\)](#)
- [EBS optimization supported \(p. 1961\)](#)

EBS optimized by default

The following tables list the instance types that support EBS optimization and EBS optimization is enabled by default. There is no need to enable EBS optimization and no effect if you disable EBS optimization.

Note

You can also view this information programmatically using the AWS CLI. For more information, see [View instances types that support EBS optimization \(p. 1963\)](#).

Topics

- [General purpose \(p. 1942\)](#)
- [Compute optimized \(p. 1948\)](#)
- [Memory optimized \(p. 1952\)](#)
- [Storage optimized \(p. 1958\)](#)
- [Accelerated computing \(p. 1960\)](#)

General purpose

Important

Instances indicated with an asterisk (*) can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

Instances not indicated with an asterisk can sustain the maximum performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

Compute optimized

Important

Instances indicated with an asterisk (*) can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

Amazon Elastic Compute Cloud
User Guide for Windows Instances
EBS optimization

Instances not indicated with an asterisk can sustain the maximum performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

Storage optimized

Important

Instances indicated with an asterisk (*) can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

Instances not indicated with an asterisk can sustain the maximum performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

Instance size	Baseline bandwidth (Mbps)	Maximum bandwidth (Mbps)	Baseline throughput (MB/s, 128 KiB I/O)	Maximum throughput (MB/s, 128 KiB I/O)	Baseline IOPS (16 KiB I/O)	Maximum IOPS (16 KiB I/O)

EBS optimization supported

The following table lists the instance types that support EBS optimization but EBS optimization is not enabled by default. You can enable EBS optimization when you launch these instances or after they are running. Instances must have EBS optimization enabled to achieve the level of performance described. When you enable EBS optimization for an instance that is not EBS-optimized by default, you pay an additional low, hourly fee for the dedicated capacity. For pricing information, see EBS-Optimized Instances on the [Amazon EC2 Pricing, On-Demand Pricing page](#).

Note

You can also view this information programmatically using the AWS CLI. For more information, see [View instances types that support EBS optimization \(p. 1963\)](#).

Instance size	Maximum bandwidth (Mbps)	Maximum throughput (MB/s, 128 KiB I/O)	Maximum IOPS (16 KiB I/O)
c1.xlarge	1000	125.0	8000
c3.xlarge	500	62.5	4000
c3.2xlarge	1000	125.0	8000
c3.4xlarge	2000	250.0	16000
g2.2xlarge	1000	125.0	8000
i2.xlarge	500	62.5	4000
i2.2xlarge	1000	125.0	8000
i2.4xlarge	2000	250.0	16000
m1.large	500	62.5	4000
m1.xlarge	1000	125.0	8000
m2.2xlarge	500	62.5	4000
m2.4xlarge	1000	125.0	8000
m3.xlarge	500	62.5	4000
m3.2xlarge	1000	125.0	8000
r3.xlarge	500	62.5	4000
r3.2xlarge	1000	125.0	8000
r3.4xlarge	2000	250.0	16000

The i2.8xlarge, c3.8xlarge, and r3.8xlarge instances do not have dedicated EBS bandwidth and therefore do not offer EBS optimization. On these instances, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

Get maximum performance

You can use the EBSIOBalance% and EBSByteBalance% metrics to help you determine whether your instances are sized correctly. You can view these metrics in the CloudWatch console and set an alarm that is triggered based on a threshold you specify. These metrics are expressed as a percentage. Instances with a consistently low balance percentage are candidates to size up. Instances where the balance percentage never drops below 100% are candidates for downsizing. For more information, see [Monitor your instances using CloudWatch \(p. 1183\)](#).

The high memory instances are designed to run large in-memory databases, including production deployments of the SAP HANA in-memory database, in the cloud. To maximize EBS performance, use high memory instances with an even number of io1 or io2 volumes with identical provisioned performance. For example, for IOPS heavy workloads, use four io1 or io2 volumes with 40,000 provisioned IOPS to get the maximum 160,000 instance IOPS. Similarly, for throughput heavy workloads,

use six io1 or io2 volumes with 48,000 provisioned IOPS to get the maximum 4,750 MB/s throughput. For additional recommendations, see [Storage Configuration for SAP HANA](#).

Considerations

- G4dn, I3en, M5a, M5ad, R5a, R5ad, T3, T3a, and Z1d instances launched after February 26, 2020 provide the maximum performance listed in the table above. To get the maximum performance from an instance launched before February 26, 2020, stop and start it.
- C5, C5d, C5n, M5, M5d, M5n, M5dn, R5, R5d, R5n, R5dn, and P3dn instances launched after December 3, 2019 provide the maximum performance listed in the table above. To get the maximum performance from an instance launched before December 3, 2019, stop and start it.
- u-6tb1.metal, u-9tb1.metal, and u-12tb1.metal instances launched after March 12, 2020 provide the performance in the table above. Instances of these types launched before March 12, 2020 might provide lower performance. To get the maximum performance from an instance launched before March 12, 2020, contact your account team to upgrade the instance at no additional cost.

View instances types that support EBS optimization

You can use the AWS CLI to view the instances types in the current Region that support EBS optimization.

To view the instance types that support EBS optimization and that have it enabled by default

Use the following [describe-instance-types](#) command.

```
aws ec2 describe-instance-types ^
--query "InstanceTypes[].{InstanceType:InstanceType,\\"MaxBandwidth(Mb/s)\":EbsInfo.EbsOptimizedInfo.MaximumBandwidthInMbps,MaxIOPS:EbsInfo.EbsOptimizedInfo.MaximumIops,\\"MaxThroughput(MB/s)\":EbsInfo.EbsOptimizedInfo.MaximumThroughputInMBps}" ^
--filters Name=ebs-info.ebs-optimized-support,Values=default --output=table
```

Example output for eu-west-1:

DescribeInstanceTypes					
EBSOptimized	InstanceType	MaxBandwidth(Mb/s)	MaxIOPS	MaxThroughput(MB/s)	
default	m5dn.8xlarge	6800	30000	850.0	
default	m6gd.xlarge	4750	20000	593.75	
default	c4.4xlarge	2000	16000	250.0	
default	r4.16xlarge	14000	75000	1750.0	
default	m5ad.large	2880	16000	360.0	
...					

To view the instance types that support EBS optimization but do not have it enabled by default

Use the following [describe-instance-types](#) command.

```
aws ec2 describe-instance-types ^
```

```
--query "InstanceTypes[].[InstanceType:InstanceType,\\"MaxBandwidth(Mb/s)\\":EbsInfo.EbsOptimizedInfo.MaximumBandwidthInMbps,MaxIOPS:EbsInfo.EbsOptimizedInfo.MaximumIops,\\"MaxThroughput(MB/s)\\":EbsInfo.EbsOptimizedInfo.MaximumThroughputInMBps}" ^  
--filters Name=ebs-info.ebs-optimized-support,Values=supported --output=table
```

Example output for eu-west-1:

DescribeInstanceTypes				
EBSOptimized	InstanceType	MaxBandwidth(Mb/s)	MaxIOPS	MaxThroughput(MB/s)
supported	m2.4xlarge	1000	8000	125.0

supported	m3.xlarge	500	4000	62.5
supported	r3.2xlarge	1000	8000	125.0
...				

Enable EBS optimization at launch

You can enable optimization for an instance by setting its attribute for EBS optimization.

To enable Amazon EBS optimization when launching an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Launch Instance**.
3. In **Step 1: Choose an Amazon Machine Image (AMI)**, select an AMI.
4. In **Step 2: Choose an Instance Type**, select an instance type that is listed as supporting Amazon EBS optimization.
5. In **Step 3: Configure Instance Details**, complete the fields that you need and choose **Launch as EBS-optimized instance**. If the instance type that you selected in the previous step doesn't support Amazon EBS optimization, this option is not present. If the instance type that you selected is Amazon EBS-optimized by default, this option is selected and you can't deselect it.
6. Follow the directions to complete the wizard and launch your instance.

To enable EBS optimization when launching an instance using the command line

You can use one of the following commands with the corresponding option. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [run-instances](#) with `--ebs-optimized` (AWS CLI)
- [New-EC2Instance](#) with `-EbsOptimized` (AWS Tools for Windows PowerShell)

Enable EBS optimization for an existing instance

You can enable or disable optimization for an existing instance by modifying its Amazon EBS-optimized instance attribute. If the instance is running, you must stop it first.

Warning

When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

To enable EBS optimization for an existing instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Instances**, and select the instance.
3. To stop the instance, choose **Actions**, **Instance state**, **Stop instance**. It can take a few minutes for the instance to stop.
4. With the instance still selected, choose **Actions**, **Instance settings**, **Change instance type**.
5. For **Change Instance Type**, do one of the following:
 - If the instance type of your instance is Amazon EBS–optimized by default, **EBS-optimized** is selected and you can't change it. You can choose **Cancel**, because Amazon EBS optimization is already enabled for the instance.
 - If the instance type of your instance supports Amazon EBS optimization, choose **EBS-optimized** and then choose **Apply**.
 - If the instance type of your instance does not support Amazon EBS optimization, you can't choose **EBS-optimized**. You can select an instance type from **Instance type** that supports Amazon EBS optimization, choose **EBS-optimized**, and then choose **Apply**.
6. Choose **Instance state**, **Start instance**.

To enable EBS optimization for an existing instance using the command line

1. If the instance is running, use one of the following commands to stop it:
 - [stop-instances](#) (AWS CLI)
 - [Stop-EC2Instance](#) (AWS Tools for Windows PowerShell)
2. To enable EBS optimization, use one of the following commands with the corresponding option:
 - [modify-instance-attribute](#) with `--ebs-optimized` (AWS CLI)
 - [Edit-EC2InstanceAttribute](#) with `-EbsOptimized` (AWS Tools for Windows PowerShell)

Amazon EBS volume performance on Windows instances

Several factors, including I/O characteristics and the configuration of your instances and volumes, can affect the performance of Amazon EBS. Customers who follow the guidance on our Amazon EBS and Amazon EC2 product detail pages typically achieve good performance out of the box. However, there are some cases where you may need to do some tuning in order to achieve peak performance on the platform. This topic discusses general best practices as well as performance tuning that is specific to certain use cases. We recommend that you tune performance with information from your actual workload, in addition to benchmarking, to determine your optimal configuration. After you learn the basics of working with EBS volumes, it's a good idea to look at the I/O performance you require and at your options for increasing Amazon EBS performance to meet those requirements.

AWS updates to the performance of EBS volume types might not immediately take effect on your existing volumes. To see full performance on an older volume, you might first need to perform a `ModifyVolume` action on it. For more information, see [Modifying the Size, IOPS, or Type of an EBS Volume on Windows](#).

Contents

- [Amazon EBS performance tips \(p. 1966\)](#)
- [I/O characteristics and monitoring \(p. 1967\)](#)
- [Initialize Amazon EBS volumes \(p. 1970\)](#)
- [RAID configuration on Windows \(p. 1972\)](#)
- [Benchmark EBS volumes \(p. 1976\)](#)

Amazon EBS performance tips

These tips represent best practices for getting optimal performance from your EBS volumes in a variety of user scenarios.

Use EBS-optimized instances

On instances without support for EBS-optimized throughput, network traffic can contend with traffic between your instance and your EBS volumes; on EBS-optimized instances, the two types of traffic are kept separate. Some EBS-optimized instance configurations incur an extra cost (such as C3, R3, and M3), while others are always EBS-optimized at no extra cost (such as M4, C4, C5, and D2). For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).

Understand how performance is calculated

When you measure the performance of your EBS volumes, it is important to understand the units of measure involved and how performance is calculated. For more information, see [I/O characteristics and monitoring \(p. 1967\)](#).

Understand your workload

There is a relationship between the maximum performance of your EBS volumes, the size and number of I/O operations, and the time it takes for each action to complete. Each of these factors (performance, I/O, and latency) affects the others, and different applications are more sensitive to one factor or another.

Be aware of the performance penalty When initializing volumes from snapshots

There is a significant increase in latency when you first access each block of data on a new EBS volume that was created from a snapshot. You can avoid this performance hit using one of the following options:

- Access each block prior to putting the volume into production. This process is called *initialization* (formerly known as pre-warming). For more information, see [Initialize Amazon EBS volumes \(p. 1970\)](#).
- Enable fast snapshot restore on a snapshot to ensure that the EBS volumes created from it are fully-initialized at creation and instantly deliver all of their provisioned performance. For more information, see [Amazon EBS fast snapshot restore \(p. 1934\)](#).

Factors that can degrade HDD performance

When you create a snapshot of a Throughput Optimized HDD (st1) or Cold HDD (sc1) volume, performance may drop as far as the volume's baseline value while the snapshot is in progress. This behavior is specific to these volume types. Other factors that can limit performance include driving more throughput than the instance can support, the performance penalty encountered while initializing volumes created from a snapshot, and excessive amounts of small, random I/O on the volume. For more information about calculating throughput for HDD volumes, see [Amazon EBS volume types \(p. 1707\)](#).

Your performance can also be impacted if your application isn't sending enough I/O requests. This can be monitored by looking at your volume's queue length and I/O size. The queue length is the number of pending I/O requests from your application to your volume. For maximum consistency, HDD-backed volumes must maintain a queue length (rounded to the nearest whole number) of 4 or more when performing 1 MiB sequential I/O. For more information about ensuring consistent performance of your volumes, see [I/O characteristics and monitoring \(p. 1967\)](#)

Use RAID 0 to maximize utilization of instance resources

Some instance types can drive more I/O throughput than what you can provision for a single EBS volume. You can join multiple volumes together in a RAID 0 configuration to use the available bandwidth for these instances. For more information, see [RAID configuration on Windows \(p. 1972\)](#).

Track performance using Amazon CloudWatch

Amazon Web Services provides performance metrics for Amazon EBS that you can analyze and view with Amazon CloudWatch and status checks that you can use to monitor the health of your volumes. For more information, see [Monitor the status of your volumes \(p. 1746\)](#).

I/O characteristics and monitoring

On a given volume configuration, certain I/O characteristics drive the performance behavior for your EBS volumes. SSD-backed volumes—General Purpose SSD (gp2 and gp3) and Provisioned IOPS SSD (io1 and io2)—deliver consistent performance whether an I/O operation is random or sequential. HDD-backed volumes—Throughput Optimized HDD (st1) and Cold HDD (sc1)—deliver optimal performance only when I/O operations are large and sequential. To understand how SSD and HDD volumes will perform in your application, it is important to know the connection between demand on the volume, the quantity of IOPS available to it, the time it takes for an I/O operation to complete, and the volume's throughput limits.

IOPS

IOPS are a unit of measure representing input/output operations per second. The operations are measured in KiB, and the underlying drive technology determines the maximum amount of data that a volume type counts as a single I/O. I/O size is capped at 256 KiB for SSD volumes and 1,024 KiB for HDD volumes because SSD volumes handle small or random I/O much more efficiently than HDD volumes.

When small I/O operations are physically sequential, Amazon EBS attempts to merge them into a single I/O operation up to the maximum I/O size. Similarly, when I/O operations are larger than the maximum I/O size, Amazon EBS attempts to split them into smaller I/O operations. The following table shows some examples.

Volume type	Maximum I/O size	I/O operations from your application	Number of IOPS	Notes
SSD	256 KiB	1 x 1024 KiB I/O operation	4 ($1,024 \div 256 = 4$)	Amazon EBS splits the 1,024 I/O operation into four smaller 256 KiB operations.
		8 x sequential 32 KiB I/O operations	1 ($8 \times 32 = 256$)	Amazon EBS merges the eight sequential 32 KiB I/O operations into a single 256 KiB operation.
		8 random 32 KiB I/O operations	8	Amazon EBS counts random

Volume type	Maximum I/O size	I/O operations from your application	Number of IOPS	Notes
				I/O operations separately.
HDD	1,024 KiB	1 x 1024 KiB I/O operation	1	The I/O operation is already equal to the maximum I/O size. It is not merged or split.
		8 x sequential 128 KiB I/O operations	1 (8x128=1,024)	Amazon EBS merges the eight sequential 128 KiB I/O operations into a single 1,024 KiB I/O operation.
		8 random 32 KiB I/O operations	8	Amazon EBS counts random I/O operations separately.

Consequently, when you create an SSD-backed volume supporting 3,000 IOPS (either by provisioning a Provisioned IOPS SSD volume at 3,000 IOPS or by sizing a General Purpose SSD volume at 1,000 GiB), and you attach it to an EBS-optimized instance that can provide sufficient bandwidth, you can transfer up to 3,000 I/Os of data per second, with throughput determined by I/O size.

Volume queue length and latency

The volume queue length is the number of pending I/O requests for a device. Latency is the true end-to-end client time of an I/O operation, in other words, the time elapsed between sending an I/O to EBS and receiving an acknowledgement from EBS that the I/O read or write is complete. Queue length must be correctly calibrated with I/O size and latency to avoid creating bottlenecks either on the guest operating system or on the network link to EBS.

Optimal queue length varies for each workload, depending on your particular application's sensitivity to IOPS and latency. If your workload is not delivering enough I/O requests to fully use the performance available to your EBS volume, then your volume might not deliver the IOPS or throughput that you have provisioned.

Transaction-intensive applications are sensitive to increased I/O latency and are well-suited for SSD-backed volumes. You can maintain high IOPS while keeping latency down by maintaining a low queue length and a high number of IOPS available to the volume. Consistently driving more IOPS to a volume than it has available can cause increased I/O latency.

Throughput-intensive applications are less sensitive to increased I/O latency, and are well-suited for HDD-backed volumes. You can maintain high throughput to HDD-backed volumes by maintaining a high queue length when performing large, sequential I/O.

I/O size and volume throughput limits

For SSD-backed volumes, if your I/O size is very large, you may experience a smaller number of IOPS than you provisioned because you are hitting the throughput limit of the volume. For example, a gp2 volume under 1,000 GiB with burst credits available has an IOPS limit of 3,000 and a volume throughput limit of 250 MiB/s. If you are using a 256 KiB I/O size, your volume reaches its throughput limit at 1000 IOPS ($1000 \times 256 \text{ KiB} = 250 \text{ MiB}$). For smaller I/O sizes (such as 16 KiB), this same volume can sustain

3,000 IOPS because the throughput is well below 250 MiB/s. (These examples assume that your volume's I/O is not hitting the throughput limits of the instance.) For more information about the throughput limits for each EBS volume type, see [Amazon EBS volume types \(p. 1707\)](#).

For smaller I/O operations, you may see a higher-than-provisioned IOPS value as measured from inside your instance. This happens when the instance operating system merges small I/O operations into a larger operation before passing them to Amazon EBS.

If your workload uses sequential I/Os on HDD-backed st1 and sc1 volumes, you may experience a higher than expected number of IOPS as measured from inside your instance. This happens when the instance operating system merges sequential I/Os and counts them in 1,024 KiB-sized units. If your workload uses small or random I/Os, you may experience a lower throughput than you expect. This is because we count each random, non-sequential I/O toward the total IOPS count, which can cause you to hit the volume's IOPS limit sooner than expected.

Important

Whatever your EBS volume type, if you are not experiencing the IOPS or throughput you expect in your configuration, ensure that your EC2 instance bandwidth is not the limiting factor. You should always use a current-generation, EBS-optimized instance (or one that includes 10 Gb/s network connectivity) for optimal performance. For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#). Another possible cause for not experiencing the expected IOPS is that you are not driving enough I/O to the EBS volumes.

Monitor I/O characteristics using CloudWatch

You can monitor these I/O characteristics with each volume's [CloudWatch volume metrics \(p. 1980\)](#). Important metrics to consider include the following:

- `BurstBalance`
- `VolumeReadBytes`
- `VolumeWriteBytes`
- `VolumeReadOps`
- `VolumeWriteOps`
- `VolumeQueueLength`

`BurstBalance` displays the burst bucket balance for gp2, st1, and sc1 volumes as a percentage of the remaining balance. When your burst bucket is depleted, volume I/O (for gp2 volumes) or volume throughput (for st1 and sc1 volumes) is throttled to the baseline. Check the `BurstBalance` value to determine whether your volume is being throttled for this reason. For a complete list of the available Amazon EBS metrics, see [Amazon EBS metrics \(p. 1979\)](#) and [Amazon EBS metrics for Nitro-based instances \(p. 1190\)](#).

HDD-backed st1 and sc1 volumes are designed to perform best with workloads that take advantage of the 1,024 KiB maximum I/O size. To determine your volume's average I/O size, divide `VolumeWriteBytes` by `VolumeWriteOps`. The same calculation applies to read operations. If average I/O size is below 64 KiB, increasing the size of the I/O operations sent to an st1 or sc1 volume should improve performance.

Note

If average I/O size is at or near 44 KiB, you might be using an instance or kernel without support for indirect descriptors. Any Linux kernel 3.8 and above has this support, as well as any current-generation instance.

If your I/O latency is higher than you require, check `VolumeQueueLength` to make sure your application is not trying to drive more IOPS than you have provisioned. If your application requires a greater number of IOPS than your volume can provide, you should consider using one of the following:

- A larger gp2 volume that provides enough baseline IOPS performance
- A gp3, io1, or io2 volume that is provisioned with enough IOPS to achieve the required latency

Related resources

For more information about Amazon EBS I/O characteristics, see the following re:Invent presentation: [Amazon EBS: Designing for Performance](#).

Initialize Amazon EBS volumes

Empty EBS volumes receive their maximum performance the moment that they are created and do not require initialization (formerly known as pre-warming).

For volumes that were created from snapshots, the storage blocks must be pulled down from Amazon S3 and written to the volume before you can access them. This preliminary action takes time and can cause a significant increase in the latency of I/O operations the first time each block is accessed. Volume performance is achieved after all blocks have been downloaded and written to the volume.

Important

While initializing Provisioned IOPS SSD volumes that were created from snapshots, the performance of the volume may drop below 50 percent of its expected level, which causes the volume to display a warning state in the **I/O Performance** status check. This is expected, and you can ignore the warning state on Provisioned IOPS SSD volumes while you are initializing them. For more information, see [EBS volume status checks \(p. 1747\)](#).

For most applications, amortizing the initialization cost over the lifetime of the volume is acceptable. To avoid this initial performance hit in a production environment, you can use one of the following options:

- Force the immediate initialization of the entire volume. For more information, see [Initialize Amazon EBS volumes on Windows \(p. 1970\)](#).
- Enable fast snapshot restore on a snapshot to ensure that the EBS volumes created from it are fully-initialized at creation and instantly deliver all of their provisioned performance. For more information, see [Amazon EBS fast snapshot restore \(p. 1934\)](#).

Initialize Amazon EBS volumes on Windows

New EBS volumes receive their maximum performance the moment that they are available and do not require initialization (formerly known as pre-warming). For volumes that have been created from snapshots, use **dd** or **fio** for Windows to read from all of the blocks on a volume. All existing data on the volume will be preserved.

For information about initializing Amazon EBS volumes on Linux, see [Initializing Amazon EBS volumes on Linux](#).

Before using either tool, gather information about the disks on your system as follows:

To gather information about the system disks

1. Use the **wmic** command to list the available disks on your system:

```
wmic diskdrive get size,deviceid
```

The following is example output:

DeviceID	Size
\.\PHYSICALDRIVE2	80517265920

```
\.\PHYSICALDRIVE1 80517265920
\.\PHYSICALDRIVE0 128849011200
\.\PHYSICALDRIVE3 107372805120
```

2. Identify the disk to initialize using **dd** or **fio**. The C: drive is on \.\PHYSICALDRIVE0. You can use the diskmgmt.msc utility to compare drive letters to disk drive numbers if you are not sure which drive number to use.

Use dd

Complete the following procedures to install and use **dd** to initialize a volume.

Important considerations

- Initializing a volume takes from several minutes up to several hours, depending on your EC2 instance bandwidth, the IOPS provisioned for the volume, and the size of the volume.
- Incorrect use of **dd** can easily destroy a volume's data. Be sure to follow this procedure precisely.

To install dd for Windows

The **dd** for Windows program provides a similar experience to the **dd** program that is commonly available for Linux and Unix systems, and it enables you to initialize Amazon EBS volumes that have been created from snapshots. The most recent beta versions support the /dev/null virtual device. If you install an earlier version, you can use the nul virtual device instead. Full documentation is available at <http://www.chrysocome.net/dd>.

1. Download the most recent binary version of **dd** for Windows from <http://www.chrysocome.net/dd>.
2. (Optional) Create a folder for command line utilities that is easy to locate and remember, such as C:\bin. If you already have a designated folder for command line utilities, you can use that folder instead in the following step.
3. Unzip the binary package and copy the dd.exe file to your command line utilities folder (for example, C:\bin).
4. Add the command line utilities folder to your Path environment variable so you can run the programs in that folder from anywhere.
 - a. Choose **Start**, open the context (right-click) menu for **Computer**, and then choose **Properties**.
 - b. Choose **Advanced system settings**, **Environment Variables**.
 - c. For **System Variables**, select the variable **Path** and choose **Edit**.
 - d. For **Variable value**, append a semicolon and the location of your command line utility folder (**;C:\bin**) to the end of the existing value.
 - e. Choose **OK** to close the **Edit System Variable** window.
5. Open a new command prompt window. The previous step doesn't update the environment variables in your current command prompt windows. The command prompt windows that you open now that you completed the previous step are updated.

To initialize a volume using dd for Windows

Run the following command to read all blocks on the specified device (and send the output to the /dev/null virtual device). This command safely initializes your existing data.

```
dd if=\.\PHYSICALDRIVEn of=/dev/null bs=1M --progress --size
```

You might get an error if **dd** attempts to read beyond the end of the volume. You can safely ignore this error.

If you used an earlier version of the **dd** command, it does not support the /dev/null device. Instead, you can use the nul device as follows.

```
dd if=\\.\PHYSICALDRIVE $n$  of=nul bs=1M --progress --size
```

Use **fio**

Complete the following procedures to install and use **fio** to initialize a volume.

To install **fio** for Windows

The **fio** for Windows program provides a similar experience to the **fio** program that is commonly available for Linux and Unix systems, and it allows you to initialize Amazon EBS volumes created from snapshots. For more information, see <https://github.com/axboe/fio>.

1. Download the [fio MSI](#) installer by expanding **Assets** for the latest release and selecting the MSI installer.
2. Install **fio**.

To initialize a volume using **fio** for Windows

1. Run a command similar to the following to initialize a volume:

```
fio --filename=\\.\PHYSICALDRIVE $n$  --rw=read --bs=128k --iodepth=32 --direct=1 --name=volume-initialize
```

2. When the operation completes, you are ready to use your new volume. For more information, see [Make an Amazon EBS volume available for use on Windows \(p. 1731\)](#).

RAID configuration on Windows

With Amazon EBS, you can use any of the standard RAID configurations that you can use with a traditional bare metal server, as long as that particular RAID configuration is supported by the operating system for your instance. This is because all RAID is accomplished at the software level.

Amazon EBS volume data is replicated across multiple servers in an Availability Zone to prevent the loss of data from the failure of any single component. This replication makes Amazon EBS volumes ten times more reliable than typical commodity disk drives. For more information, see [Amazon EBS Availability and Durability](#) in the Amazon EBS product detail pages.

Note

You should avoid booting from a RAID volume. If one of the devices fails, you may be unable to boot the operating system.

If you need to create a RAID array on a Linux instance, see [RAID configuration on Linux](#) in the *Amazon EC2 User Guide for Linux Instances*.

Contents

- [RAID configuration options \(p. 1972\)](#)
- [Create a RAID 0 array on Windows \(p. 1973\)](#)
- [Create snapshots of volumes in a RAID array \(p. 1976\)](#)

RAID configuration options

Creating a RAID 0 array allows you to achieve a higher level of performance for a file system than you can provision on a single Amazon EBS volume. Use RAID 0 when I/O performance is of the utmost

importance. With RAID 0, I/O is distributed across the volumes in a stripe. If you add a volume, you get the straight addition of throughput and IOPS. However, keep in mind that performance of the stripe is limited to the worst performing volume in the set, and that the loss of a single volume in the set results in a complete data loss for the array.

The resulting size of a RAID 0 array is the sum of the sizes of the volumes within it, and the bandwidth is the sum of the available bandwidth of the volumes within it. For example, two 500 GiB io1 volumes with 4,000 provisioned IOPS each create a 1000 GiB RAID 0 array with an available bandwidth of 8,000 IOPS and 1,000 MiB/s of throughput.

Important

RAID 5 and RAID 6 are not recommended for Amazon EBS because the parity write operations of these RAID modes consume some of the IOPS available to your volumes. Depending on the configuration of your RAID array, these RAID modes provide 20-30% fewer usable IOPS than a RAID 0 configuration. Increased cost is a factor with these RAID modes as well; when using identical volume sizes and speeds, a 2-volume RAID 0 array can outperform a 4-volume RAID 6 array that costs twice as much.

RAID 1 is also not recommended for use with Amazon EBS. RAID 1 requires more Amazon EC2 to Amazon EBS bandwidth than non-RAID configurations because the data is written to multiple volumes simultaneously. In addition, RAID 1 does not provide any write performance improvement.

Create a RAID 0 array on Windows

This documentation provides a basic RAID 0 setup example.

Before you perform this procedure, you need to decide how large your RAID 0 array should be and how many IOPS you want to provision.

Use the following procedure to create the RAID 0 array. Note that you can get directions for Linux instances from [Create a RAID 0 array on Linux](#) in the *Amazon EC2 User Guide for Linux Instances*.

To create a RAID 0 array on Windows

1. Create the Amazon EBS volumes for your array. For more information, see [Create an Amazon EBS volume \(p. 1726\)](#).

Important

Create volumes with identical size and IOPS performance values for your array. Make sure you do not create an array that exceeds the available bandwidth of your EC2 instance.

2. Attach the Amazon EBS volumes to the instance that you want to host the array. For more information, see [Attach an Amazon EBS volume to an instance \(p. 1729\)](#).
3. Connect to your Windows instance. For more information, see [Connect to your Windows instance \(p. 626\)](#).
4. Open a command prompt and type the **diskpart** command.

```
diskpart

Microsoft DiskPart version 6.1.7601
Copyright (C) 1999-2008 Microsoft Corporation.
On computer: WIN-BM6QPPL51C0
```

5. At the DISKPART prompt, list the available disks with the following command.

```
DISKPART> list disk

Disk ###  Status       Size     Free      Dyn  Gpt
-----  -----  -----  -----  -----  -----
Disk 0    Online      30 GB    0 B
```

Disk 1	Online	8 GB	0 B
Disk 2	Online	8 GB	0 B

Identify the disks you want to use in your array and take note of their disk numbers.

6. Each disk you want to use in your array must be an online dynamic disk that does not contain any existing volumes. Use the following steps to convert basic disks to dynamic disks and to delete any existing volumes.
 - a. Select a disk you want to use in your array with the following command, substituting *n* with your disk number.

```
DISKPART> select disk n  
Disk n is now the selected disk.
```

- b. If the selected disk is listed as Offline, bring it online by running the **online disk** command.
- c. If the selected disk does not have an asterisk in the Dyn column in the previous **list disk** command output, you need to convert it to a dynamic disk.

```
DISKPART> convert dynamic
```

Note

If you receive an error that the disk is write protected, you can clear the read-only flag with the **ATTRIBUTE DISK CLEAR READONLY** command and then try the dynamic disk conversion again.

- d. Use the **detail disk** command to check for existing volumes on the selected disk.

```
DISKPART> detail disk  
  
XENSRC PVDISK SCSI Disk Device  
Disk ID: 2D8BF659  
Type : SCSI  
Status : Online  
Path : 0  
Target : 1  
LUN ID : 0  
Location Path : PCIROOT(0)#PCI(0300)#SCSI(P00T01L00)  
Current Read-only State : No  
Read-only : No  
Boot Disk : No  
Pagefile Disk : No  
Hibernation File Disk : No  
Crashdump Disk : No  
Clustered Disk : No  
  
Volume ### Ltr Label Fs Type Size Status Info  
----- -- -- -- -- --  
Volume 2 D NEW VOLUME FAT32 Simple 8189 MB Healthy
```

Note any volume numbers on the disk. In this example, the volume number is 2. If there are no volumes, you can skip the next step.

- e. (Only required if volumes were identified in the previous step) Select and delete any existing volumes on the disk that you identified in the previous step.

Warning

This destroys any existing data on the volume.

- i. Select the volume, substituting *n* with your volume number.

```
DISKPART> select volume n
Volume n is the selected volume.
```

- ii. Delete the volume.

```
DISKPART> delete volume
DiskPart successfully deleted the volume.
```

- iii. Repeat these substeps for each volume you need to delete on the selected disk.

- f. Repeat [Step 6 \(p. 1974\)](#) for each disk you want to use in your array.

7. Verify that the disks you want to use are now dynamic. In this case, we're using disks 1 and 2 for the RAID volume.

```
DISKPART> list disk
Disk ### Status Size Free Dyn Gpt
----- -----
Disk 0 Online 30 GB 0 B
Disk 1 Online 8 GB 0 B *
Disk 2 Online 8 GB 0 B *
```

8. Create your raid array. On Windows, a RAID 0 volume is referred to as a striped volume.

To create a striped volume array on disks 1 and 2, use the following command (note the `stripe` option to stripe the array):

```
DISKPART> create volume stripe disk=1,2
DiskPart successfully created the volume.
```

9. Verify your new volume.

```
DISKPART> list volume
DISKPART> list volume
Volume ### Ltr Label Fs Type Size Status Info
----- -- -- --
Volume 0 C NTFS Partition 29 GB Healthy System
Volume 1 RAW Stripe 15 GB Healthy
```

Note that the Type column now indicates that Volume 1 is a `stripe` volume.

10. Select and format your volume so that you can begin using it.

- a. Select the volume you want to format, substituting *n* with your volume number.

```
DISKPART> select volume n
Volume n is the selected volume.
```

- b. Format the volume.

Note

To perform a full format, omit the `quick` option.

```
DISKPART> format quick recommended label="My new volume"
100 percent completed
```

```
DiskPart successfully formatted the volume.
```

- c. Assign an available drive letter to your volume.

```
DISKPART> assign letter f
```

```
DiskPart successfully assigned the drive letter or mount point.
```

Your new volume is now ready to use.

Create snapshots of volumes in a RAID array

If you want to back up the data on the EBS volumes in a RAID array using snapshots, you must ensure that the snapshots are consistent. This is because the snapshots of these volumes are created independently. To restore EBS volumes in a RAID array from snapshots that are out of sync would degrade the integrity of the array.

To create a consistent set of snapshots for your RAID array, use [EBS multi-volume snapshots](#). Multi-volume snapshots allow you to take point-in-time, data coordinated, and crash-consistent snapshots across multiple EBS volumes attached to an EC2 instance. You do not have to stop your instance to coordinate between volumes to ensure consistency because snapshots are automatically taken across multiple EBS volumes. For more information, see the steps for creating multi-volume snapshots under [Creating Amazon EBS snapshots](#).

Benchmark EBS volumes

You can test the performance of Amazon EBS volumes by simulating I/O workloads. The process is as follows:

1. Launch an EBS-optimized instance.
2. Create new EBS volumes.
3. Attach the volumes to your EBS-optimized instance.
4. Configure and mount the block device.
5. Install a tool to benchmark I/O performance.
6. Benchmark the I/O performance of your volumes.
7. Delete your volumes and terminate your instance so that you don't continue to incur charges.

Important

Some of the procedures result in the destruction of existing data on the EBS volumes you benchmark. The benchmarking procedures are intended for use on volumes specially created for testing purposes, not production volumes.

Set up your instance

To get optimal performance from EBS volumes, we recommend that you use an EBS-optimized instance. EBS-optimized instances deliver dedicated throughput between Amazon EC2 and Amazon EBS, with instance. EBS-optimized instances deliver dedicated bandwidth between Amazon EC2 and Amazon EBS, with specifications depending on the instance type. For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).

To create an EBS-optimized instance, choose **Launch as an EBS-Optimized instance** when launching the instance using the Amazon EC2 console, or specify **--ebs-optimized** when using the command line. Be

sure that you launch a current-generation instance that supports this option. For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).

Set up Provisioned IOPS SSD or General Purpose SSD volumes

To create Provisioned IOPS SSD (io1 and io2) or General Purpose SSD (gp2 and gp3) volumes using the Amazon EC2 console, for **Volume type**, choose **Provisioned IOPS SSD (io1)**, **Provisioned IOPS SSD (io2)**, **General Purpose SSD (gp2)**, or **General Purpose SSD (gp3)**. At the command line, specify io1, io2, gp2, or gp3 for the **--volume-type** parameter. For io1, io2, and gp3 volumes, specify the number of I/O operations per second (IOPS) for the **--iops** parameter. For more information, see [Amazon EBS volume types \(p. 1707\)](#) and [Create an Amazon EBS volume \(p. 1726\)](#).

Set up Throughput Optimized HDD (st1) or Cold HDD (sc1) volumes

To create an st1 volume, choose **Throughput Optimized HDD** when creating the volume using the Amazon EC2 console, or specify **--type st1** when using the command line. To create an sc1 volume, choose **Cold HDD** when creating the volume using the Amazon EC2 console, or specify **--type sc1** when using the command line. For information about creating EBS volumes, see [Create an Amazon EBS volume \(p. 1726\)](#). For information about attaching these volumes to your instance, see [Attach an Amazon EBS volume to an instance \(p. 1729\)](#).

Install benchmark tools

The following table lists some of the possible tools you can use to benchmark the performance of EBS volumes.

Tool	Description
DiskSpd	<p>DiskSpd is a storage performance tool from the Windows, Windows Server, and Cloud Server Infrastructure engineering teams at Microsoft. It is available for download at https://github.com/Microsoft/diskspd/releases.</p> <p>After you download the diskspd.exe executable file, open a command prompt with administrative rights (by choosing "Run as Administrator"), and then navigate to the directory where you copied the diskspd.exe file.</p> <p>Copy the desired diskspd.exe executable file from the appropriate executable folder (amd64fre, armfre or x86fre) to a short, simple path like C:\DiskSpd. In most cases you will want the 64-bit version of DiskSpd from the amd64fre folder.</p> <p>The source code for DiskSpd is hosted on GitHub at: https://github.com/Microsoft/diskspd.</p>
CrystalDiskMark	CrystalDiskMark is a simple disk benchmark software. It is available for download at https://crystalmark.info/en/software/crystaldiskmark/ .

These benchmarking tools support a wide variety of test parameters. You should use commands that approximate the workloads your volumes will support. These commands provided below are intended as examples to help you get started.

Choose the volume queue length

Choosing the best volume queue length based on your workload and volume type.

Queue length on SSD-backed volumes

To determine the optimal queue length for your workload on SSD-backed volumes, we recommend that you target a queue length of 1 for every 1000 IOPS available (baseline for General Purpose SSD volumes

and the provisioned amount for Provisioned IOPS SSD volumes). Then you can monitor your application performance and tune that value based on your application requirements.

Increasing the queue length is beneficial until you achieve the provisioned IOPS, throughput or optimal system queue length value, which is currently set to 32. For example, a volume with 3,000 provisioned IOPS should target a queue length of 3. You should experiment with tuning these values up or down to see what performs best for your application.

Queue length on HDD-backed volumes

To determine the optimal queue length for your workload on HDD-backed volumes, we recommend that you target a queue length of at least 4 while performing 1MiB sequential I/Os. Then you can monitor your application performance and tune that value based on your application requirements. For example, a 2 TiB st1 volume with burst throughput of 500 MiB/s and IOPS of 500 should target a queue length of 4, 8, or 16 while performing 1,024 KiB, 512 KiB, or 256 KiB sequential I/Os respectively. You should experiment with tuning these values value up or down to see what performs best for your application.

Disable C-states

Before you run benchmarking, you should disable processor C-states. Temporarily idle cores in a supported CPU can enter a C-state to save power. When the core is called on to resume processing, a certain amount of time passes until the core is again fully operational. This latency can interfere with processor benchmarking routines. For more information about C-states and which EC2 instance types support them, see [Processor state control for your EC2 instance](#).

Disable C-states on Windows

You can disable C-states on Windows as follows:

1. In PowerShell, get the current active power scheme.

```
$current_scheme = powercfg /getactivescheme
```

2. Get the power scheme GUID.

```
(Get-WmiObject -class Win32_PowerPlan -Namespace "root\cimv2\power" -Filter "ElementName='High performance'").InstanceID
```

3. Get the power setting GUID.

```
(Get-WmiObject -class Win32_PowerSetting -Namespace "root\cimv2\power" -Filter "ElementName='Processor idle disable'").InstanceID
```

4. Get the power setting subgroup GUID.

```
(Get-WmiObject -class Win32_PowerSettingSubgroup -Namespace "root\cimv2\power" -Filter "ElementName='Processor power management'").InstanceID
```

5. Disable C-states by setting the value of the index to 1. A value of 0 indicates that C-states are disabled.

```
powercfg /  
setacvalueindex <power_scheme_guid> <power_setting_subgroup_guid> <power_setting_guid>  
1
```

6. Set active scheme to ensure the settings are saved.

```
powercfg /setactive <power_scheme_guid>
```

Perform benchmarking

The following procedures describe benchmarking commands for various EBS volume types.

Run the following commands on an EBS-optimized instance with attached EBS volumes. If the EBS volumes were created from snapshots, be sure to initialize them before benchmarking. For more information, see [Initialize Amazon EBS volumes \(p. 1970\)](#).

When you are finished testing your volumes, see the following topics for help cleaning up: [Delete an Amazon EBS volume \(p. 1755\)](#) and [Terminate your instance \(p. 615\)](#).

Benchmark Provisioned IOPS SSD and General Purpose SSD volumes

Run **DiskSpd** on the volume that you created.

The following command will run a 30 second random I/O test using a 20GB test file located on the C: drive, with a 25% write and 75% read ratio, and an 8K block size. It will use eight worker threads, each with four outstanding I/Os, and a write entropy value seed of 1GB. The results of the test will be saved to a text file called DiskSpeedResults.txt. These parameters simulate a SQL Server OLTP workload.

```
diskspd -b8K -d30 -o4 -t8 -h -r -w25 -L -Z1G -c20G C:\iotest.dat > DiskSpeedResults.txt
```

For more information about interpreting the results, see this tutorial: [Inspecting disk IO performance with DiskSPd](#).

Amazon CloudWatch metrics for Amazon EBS

Amazon CloudWatch metrics are statistical data that you can use to view, analyze, and set alarms on the operational behavior of your volumes.

Data is available automatically in 1-minute periods at no charge.

When you get data from CloudWatch, you can include a `Period` request parameter to specify the granularity of the returned data. This is different than the period that we use when we collect the data (1-minute periods). We recommend that you specify a period in your request that is equal to or greater than the collection period to ensure that the returned data is valid.

You can get the data using either the CloudWatch API or the Amazon EC2 console. The console takes the raw data from the CloudWatch API and displays a series of graphs based on the data. Depending on your needs, you might prefer to use either the data from the API or the graphs in the console.

Topics

- [Amazon EBS metrics \(p. 1979\)](#)
- [Dimensions for Amazon EBS metrics \(p. 1984\)](#)
- [Graphs in the Amazon EC2 console \(p. 1984\)](#)

Amazon EBS metrics

Amazon Elastic Block Store (Amazon EBS) sends data points to CloudWatch for several metrics. All Amazon EBS volume types automatically send 1-minute metrics to CloudWatch, but only when the volume is attached to an instance.

Metrics

- [Volume metrics for volumes attached to all instance types \(p. 1980\)](#)
- [Volume metrics for volumes attached to Nitro-based instance types \(p. 1983\)](#)

- [Fast snapshot restore metrics \(p. 1984\)](#)

Volume metrics for volumes attached to all instance types

The AWS/EBS namespace includes the following metrics for EBS volumes that are attached to all instance types. To get information about the available disk space from the operating system on an instance, see [View free disk space \(p. 1738\)](#).

Note

- Some metrics have differences on instances that are built on the Nitro System. For a list of these instance types, see [Instances built on the Nitro System \(p. 218\)](#).
- The AWS/EC2 namespace includes additional Amazon EBS metrics for volumes that are attached to Nitro-based instances that are not bare metal instances. For more information about these metrics see, [Amazon EBS metrics for Nitro-based instances \(p. 1190\)](#).

Metric	Description
VolumeReadBytes	<p>Provides information on the read operations in a specified period of time. The Sum statistic reports the total number of bytes transferred during the period. The Average statistic reports the average size of each read operation during the period, except on volumes attached to a Nitro-based instance, where the average represents the average over the specified period. The SampleCount statistic reports the total number of read operations during the period, except on volumes attached to a Nitro-based instance, where the sample count represents the number of data points used in the statistical calculation. For Xen instances, data is reported only when there is read activity on the volume.</p> <p>The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances.</p> <p>Units: Bytes</p>
VolumeWriteBytes	<p>Provides information on the write operations in a specified period of time. The Sum statistic reports the total number of bytes transferred during the period. The Average statistic reports the average size of each write operation during the period, except on volumes attached to a Nitro-based instance, where the average represents the average over the specified period. The SampleCount statistic reports the total number of write operations during the period, except on volumes attached to a Nitro-based instance, where the sample count represents the number of data points used in the statistical calculation. For Xen instances, data is reported only when there is write activity on the volume.</p> <p>The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances.</p> <p>Units: Bytes</p>
VolumeReadOps	The total number of read operations in a specified period of time. Note: read operations are counted on completion.

Metric	Description
	<p>To calculate the average read operations per second (read IOPS) for the period, divide the total read operations in the period by the number of seconds in that period.</p> <p>The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances.</p> <p>Units: Count</p>
VolumeWriteOps	<p>The total number of write operations in a specified period of time. Note: write operations are counted on completion.</p> <p>To calculate the average write operations per second (write IOPS) for the period, divide the total write operations in the period by the number of seconds in that period.</p> <p>The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances.</p> <p>Units: Count</p>
VolumeTotalReadTime	<p>Note This metric is not supported with Multi-Attach enabled volumes.</p> <p>The total number of seconds spent by all read operations that completed in a specified period of time. If multiple requests are submitted at the same time, this total could be greater than the length of the period. For example, for a period of 1 minutes (60 seconds): if 150 operations completed during that period, and each operation took 1 second, the value would be 150 seconds. For Xen instances, data is reported only when there is read activity on the volume.</p> <p>The Average statistic on this metric is not relevant for volumes attached to Nitro-based instances.</p> <p>The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances.</p> <p>Units: Seconds</p>

Metric	Description
VolumeTotalWriteTime	<p>Note This metric is not supported with Multi-Attach enabled volumes.</p> <p>The total number of seconds spent by all write operations that completed in a specified period of time. If multiple requests are submitted at the same time, this total could be greater than the length of the period. For example, for a period of 1 minute (60 seconds): if 150 operations completed during that period, and each operation took 1 second, the value would be 150 seconds. For Xen instances, data is reported only when there is write activity on the volume.</p> <p>The Average statistic on this metric is not relevant for volumes attached to Nitro-based instances.</p> <p>The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances.</p> <p>Units: Seconds</p>
VolumeIdleTime	<p>Note This metric is not supported with Multi-Attach enabled volumes.</p> <p>The total number of seconds in a specified period of time when no read or write operations were submitted.</p> <p>The Average statistic on this metric is not relevant for volumes attached to Nitro-based instances.</p> <p>The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances.</p> <p>Units: Seconds</p>
VolumeQueueLength	<p>The number of read and write operation requests waiting to be completed in a specified period of time.</p> <p>The Sum statistic on this metric is not relevant for volumes attached to Nitro-based instances.</p> <p>The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances.</p> <p>Units: Count</p>

Metric	Description
VolumeThroughputPercentage	<p>Note This metric is not supported with Multi-Attach enabled volumes.</p> <p>Used with Provisioned IOPS SSD volumes only. The percentage of I/O operations per second (IOPS) delivered of the total IOPS provisioned for an Amazon EBS volume. Provisioned IOPS SSD volumes deliver their provisioned performance 99.9 percent of the time.</p> <p>During a write, if there are no other pending I/O requests in a minute, the metric value will be 100 percent. Also, a volume's I/O performance may become degraded temporarily due to an action you have taken (for example, creating a snapshot of a volume during peak usage, running the volume on a non-EBS-optimized instance, or accessing data on the volume for the first time).</p> <p>Units: Percent</p>
VolumeConsumedReadWriteOps	<p>Used with Provisioned IOPS SSD volumes only. The total amount of read and write operations (normalized to 256K capacity units) consumed in a specified period of time.</p> <p>I/O operations that are smaller than 256K each count as 1 consumed IOPS. I/O operations that are larger than 256K are counted in 256K capacity units. For example, a 1024K I/O would count as 4 consumed IOPS.</p> <p>Units: Count</p>
BurstBalance	<p>Used with General Purpose SSD (gp2), Throughput Optimized HDD (st1), and Cold HDD (sc1) volumes only. Provides information about the percentage of I/O credits (for gp2) or throughput credits (for st1 and sc1) remaining in the burst bucket. Data is reported to CloudWatch only when the volume is active. If the volume is not attached, no data is reported.</p> <p>The Sum statistic on this metric is not relevant for volumes attached to instances built on the Nitro System.</p> <p>If the baseline performance of the volume exceeds the maximum burst performance, credits are never spent. If the volume is attached to an instance built on the Nitro System, the burst balance is not reported. For other instances, the reported burst balance is 100%. For more information, see gp2 volume performance (p. 1711).</p> <p>Units: Percent</p>

Volume metrics for volumes attached to Nitro-based instance types

The AWS/EC2 namespace includes additional Amazon EBS metrics for volumes that are attached to Nitro-based instances that are not bare metal instances. For more information about these metrics see, [Amazon EBS metrics for Nitro-based instances \(p. 1190\)](#).

Fast snapshot restore metrics

AWS/EBS namespace includes the following metrics for [fast snapshot restore \(p. 1934\)](#).

Metric	Description
FastSnapshotRestoreCreditsUsed	The maximum number of volume create credits that can be accumulated. This metric is reported per snapshot per Availability Zone. The most meaningful statistic is Average. The results for the Minimum and Maximum statistics are the same as for Average and could be used instead. Units: Count
FastSnapshotRestoreCreditsAvailable	The number of volume create credits available. This metric is reported per snapshot per Availability Zone. The most meaningful statistic is Average. The results for the Minimum and Maximum statistics are the same as for Average and could be used instead. Units: Count

Dimensions for Amazon EBS metrics

The supported dimension is the volume ID (VolumeId). All available statistics are filtered by volume ID.

For the [volume metrics \(p. 1980\)](#), the supported dimension is the volume ID (VolumeId). All available statistics are filtered by volume ID.

For the [fast snapshot restore metrics \(p. 1984\)](#), the supported dimensions are the snapshot ID (SnapshotId) and the Availability Zone (AvailabilityZone).

Graphs in the Amazon EC2 console

After you create a volume, you can view the volume's monitoring graphs in the Amazon EC2 console. Select a volume on the **Volumes** page in the console and choose **Monitoring**. The following table lists the graphs that are displayed. The column on the right describes how the raw data metrics from the CloudWatch API are used to produce each graph. The period for all the graphs is 5 minutes.

Graph	Description using raw metrics
Read throughput (KiB/s)	$\text{Sum}(\text{VolumeReadBytes}) / \text{Period} / 1024$
Write throughput (KiB/s)	$\text{Sum}(\text{VolumeWriteBytes}) / \text{Period} / 1024$
Read operations (Ops/s)	$\text{Sum}(\text{VolumeReadOps}) / \text{Period}$
Write operations (Ops/s)	$\text{Sum}(\text{VolumeWriteOps}) / \text{Period}$
Average queue length (Operations)	$\text{Avg}(\text{VolumeQueueLength})$
Time spent idle (%)	$\text{Sum}(\text{VolumeIdleTime}) / \text{Period} \times 100$

Graph	Description using raw metrics
Average read size (KiB/op)	<p>Avg(VolumeReadBytes) / 1024</p> <p>For Nitro-based instances, the following formula derives Average Read Size using CloudWatch Metric Math:</p> $(\text{Sum}(\text{VolumeReadBytes}) / \text{Sum}(\text{VolumeReadOps})) / 1024$ <p>The VolumeReadBytes and VolumeReadOps metrics are available in the EBS CloudWatch console.</p>
Average write size (KiB/op)	<p>Avg(VolumeWriteBytes) / 1024</p> <p>For Nitro-based instances, the following formula derives Average Write Size using CloudWatch Metric Math:</p> $(\text{Sum}(\text{VolumeWriteBytes}) / \text{Sum}(\text{VolumeWriteOps})) / 1024$ <p>The VolumeWriteBytes and VolumeWriteOps metrics are available in the EBS CloudWatch console.</p>
Average read latency (ms/op)	<p>Avg(VolumeTotalReadTime) × 1000</p> <p>For Nitro-based instances, the following formula derives Average Read Latency using CloudWatch Metric Math:</p> $(\text{Sum}(\text{VolumeTotalReadTime}) / \text{Sum}(\text{VolumeReadOps})) \times 1000$ <p>The VolumeTotalReadTime and VolumeReadOps metrics are available in the EBS CloudWatch console.</p>
Average write latency (ms/op)	<p>Avg(VolumeTotalWriteTime) × 1000</p> <p>For Nitro-based instances, the following formula derives Average Write Latency using CloudWatch Metric Math:</p> $(\text{Sum}(\text{VolumeTotalWriteTime}) / \text{Sum}(\text{VolumeWriteOps})) \times 1000$ <p>The VolumeTotalWriteTime and VolumeWriteOps metrics are available in the EBS CloudWatch console.</p>

For the average latency graphs and average size graphs, the average is calculated over the total number of operations (read or write, whichever is applicable to the graph) that completed during the period.

EventBridge for Amazon EBS

Amazon EBS sends events to Amazon EventBridge for actions performed on volumes and snapshots. With EventBridge, you can establish rules that trigger programmatic actions in response to these events. For example, you can create a rule that sends a notification to your email when a snapshot is enabled for fast snapshot restore.

Events in EventBridge are represented as JSON objects. The fields that are unique to the event are contained in the "detail" section of the JSON object. The "event" field contains the event name. The

"result" field contains the completed status of the action that triggered the event. For more information, see [Amazon EventBridge event patterns](#) in the *Amazon EventBridge User Guide*.

For more information, see [What Is Amazon EventBridge?](#) in the *Amazon EventBridge User Guide*.

Events

- [EBS volume events \(p. 1986\)](#)
- [EBS volume modification events \(p. 1989\)](#)
- [EBS snapshot events \(p. 1989\)](#)
- [EBS Snapshots Archive events \(p. 1993\)](#)
- [EBS fast snapshot restore events \(p. 1993\)](#)
- [Using AWS Lambda to handle EventBridge events \(p. 1994\)](#)

EBS volume events

Amazon EBS sends events to EventBridge when the following volume events occur.

Events

- [Create volume \(createVolume\) \(p. 1986\)](#)
- [Delete volume \(deleteVolume\) \(p. 1987\)](#)
- [Volume attach or reattach \(attachVolume, reattachVolume\) \(p. 1988\)](#)

Create volume (createVolume)

The `createVolume` event is sent to your AWS account when an action to create a volume completes. However it is not saved, logged, or archived. This event can have a result of either `available` or `failed`. Creation will fail if an invalid AWS KMS key was provided, as shown in the examples below.

Event data

The listing below is an example of a JSON object emitted by EBS for a successful `createVolume` event.

```
{  
    "version": "0",  
    "id": "01234567-0123-0123-0123-012345678901",  
    "detail-type": "EBS Volume Notification",  
    "source": "aws.ec2",  
    "account": "012345678901",  
    "time": "yyyy-mm-ddThh:mm:ssZ",  
    "region": "us-east-1",  
    "resources": [  
        "arn:aws:ec2:us-east-1:012345678901:volume/vol-01234567"  
    ],  
    "detail": {  
        "result": "available",  
        "cause": "",  
        "event": "createVolume",  
        "request-id": "01234567-0123-0123-0123-0123456789ab"  
    }  
}
```

The listing below is an example of a JSON object emitted by EBS after a failed `createVolume` event. The cause for the failure was a disabled KMS key.

```
{
```

```
"version": "0",
"id": "01234567-0123-0123-0123-0123456789ab",
"detail-type": "EBS Volume Notification",
"source": "aws.ec2",
"account": "012345678901",
"time": "yyyy-mm-ddThh:mm:ssZ",
"region": "sa-east-1",
"resources": [
    "arn:aws:ec2:sa-east-1:0123456789ab:volume/vol-01234567",
],
"detail": {
    "event": "createVolume",
    "result": "failed",
    "cause": "arn:aws:kms:sa-east-1:0123456789ab:key/01234567-0123-0123-0123-0123456789ab is disabled.",
    "request-id": "01234567-0123-0123-0123-0123456789ab",
}
}
```

The following is an example of a JSON object that is emitted by EBS after a failed `createVolume` event. The cause for the failure was a KMS key pending import.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "EBS Volume Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "sa-east-1",
    "resources": [
        "arn:aws:ec2:sa-east-1:0123456789ab:volume/vol-01234567",
    ],
    "detail": {
        "event": "createVolume",
        "result": "failed",
        "cause": "arn:aws:kms:sa-east-1:0123456789ab:key/01234567-0123-0123-0123-0123456789ab is pending import.",
        "request-id": "01234567-0123-0123-0123-0123456789ab",
    }
}
```

Delete volume (deleteVolume)

The `deleteVolume` event is sent to your AWS account when an action to delete a volume completes. However it is not saved, logged, or archived. This event has the result `deleted`. If the deletion does not complete, the event is never sent.

Event data

The listing below is an example of a JSON object emitted by EBS for a successful `deleteVolume` event.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Volume Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:012345678901:volume/vol-01234567"
```

```
        ],
      "detail": {
        "result": "deleted",
        "cause": "",
        "event": "deleteVolume",
        "request-id": "01234567-0123-0123-0123-0123456789ab"
      }
}
```

Volume attach or reattach (attachVolume, reattachVolume)

The `attachVolume` or `reattachVolume` event is sent to your AWS account if a volume fails to attach or reattach to an instance. However it is not saved, logged, or archived. If you use a KMS key to encrypt an EBS volume and the KMS key becomes invalid, EBS will emit an event if that KMS key is later used to attach or reattach to an instance, as shown in the examples below.

Event data

The listing below is an example of a JSON object emitted by EBS after a failed `attachVolume` event. The cause for the failure was a KMS key pending deletion.

Note

AWS may attempt to reattach to a volume following routine server maintenance.

```

EBS volume modification events

Amazon EBS sends modifyVolume events to EventBridge when a volume is modified. However it is not saved, logged, or archived.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",

    }
}
```

EBS snapshot events

Amazon EBS sends events to EventBridge when the following volume events occur.

Events

- [Create snapshot \(createSnapshot\) \(p. 1989\)](#)
- [Create snapshots \(createSnapshots\) \(p. 1990\)](#)
- [Copy snapshot \(copySnapshot\) \(p. 1991\)](#)
- [Share snapshot \(shareSnapshot\) \(p. 1992\)](#)

Create snapshot (createSnapshot)

The createSnapshot event is sent to your AWS account when an action to create a snapshot completes. However it is not saved, logged, or archived. This event can have a result of either succeeded or failed.

Event data

The listing below is an example of a JSON object emitted by EBS for a successful createSnapshot event. In the detail section, the source field contains the ARN of the source volume. The startTime and endTime fields indicate when creation of the snapshot started and completed.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
```

```
"source": "aws.ec2",
"account": "012345678901",
"time": "yyyy-mm-ddThh:mm:ssZ",
"region": "us-east-1",
"resources": [
    "arn:aws:ec2::us-west-2:snapshot/snap-01234567"
],
"detail": {
    "event": "createSnapshot",
    "result": "succeeded",
    "cause": "",
    "request-id": "",
    "snapshot_id": "arn:aws:ec2::us-west-2:snapshot/snap-01234567",
    "source": "arn:aws:ec2::us-west-2:volume/vol-01234567",
    "startTime": "yyyy-mm-ddThh:mm:ssZ",
    "endTime": "yyyy-mm-ddThh:mm:ssZ" }
```

Create snapshots (createSchemas)

The `createSchemas` event is sent to your AWS account when an action to create a multi-volume snapshot completes. This event can have a result of either succeeded or failed.

Event data

The listing below is an example of a JSON object emitted by EBS for a successful `createSchemas` event. In the `detail` section, the `source` field contains the ARNs of the source volumes of the multi-volume snapshot set. The `startTime` and `endTime` fields indicate when creation of the snapshot started and completed.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Multi-Volume Snapshots Completion Status",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2::us-east-1:snapshot/snap-01234567",
        "arn:aws:ec2::us-east-1:snapshot/snap-012345678"
    ],
    "detail": {
        "event": "createSchemas",
        "result": "succeeded",
        "cause": "",
        "request-id": "",
        "startTime": "yyyy-mm-ddThh:mm:ssZ",
        "endTime": "yyyy-mm-ddThh:mm:ssZ",
        "snapshots": [
            {
                "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-01234567",
                "source": "arn:aws:ec2::us-east-1:volume/vol-01234567",
                "status": "completed"
            },
            {
                "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-012345678",
                "source": "arn:aws:ec2::us-east-1:volume/vol-012345678",
                "status": "completed"
            }
        ]
    }
}
```

The listing below is an example of a JSON object emitted by EBS after a failed `createSnapshots` event. The cause for the failure was one or more snapshots for the multi-volume snapshot set failed to complete. The values of `snapshot_id` are the ARNs of the failed snapshots. `startTime` and `endTime` represent when the `create-snapshots` action started and ended.

```
{  
    "version": "0",  
    "id": "01234567-0123-0123-0123-012345678901",  
    "detail-type": "EBS Multi-Volume Snapshots Completion Status",  
    "source": "aws.ec2",  
    "account": "012345678901",

    "region": "us-east-1",  
    "resources": [  
        "arn:aws:ec2::us-east-1:snapshot/snap-01234567",  
        "arn:aws:ec2::us-east-1:snapshot/snap-012345678"  
    ],  
    "detail": {  
        "event": "createSnapshots",  
        "result": "failed",  
        "cause": "Snapshot snap-01234567 is in status error",  
        "request-id": "",  
        "startTime": "yyyy-mm-ddThh:mm:ssZ",  
        "endTime": "yyyy-mm-ddThh:mm:ssZ",  
        "snapshots": [  
            {  
                "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-01234567",  
                "source": "arn:aws:ec2::us-east-1:volume/vol-01234567",  
                "status": "error"  
            },  
            {  
                "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-012345678",  
                "source": "arn:aws:ec2::us-east-1:volume/vol-012345678",  
                "status": "error"  
            }  
        ]  
    }  
}
```

Copy snapshot (copySnapshot)

The `copySnapshot` event is sent to your AWS account when an action to copy a snapshot completes. However it is not saved, logged, or archived. This event can have a result of either succeeded or failed.

If you are copying the snapshot across Regions, then the event is emitted in the destination Region.

Event data

The listing below is an example of a JSON object emitted by EBS after a successful `copySnapshot` event. The value of `snapshot_id` is the ARN of the newly created snapshot. In the `detail` section, the value of `source` is the ARN of the source snapshot. `startTime` and `endTime` represent when the `copy-snapshot` action started and ended. `incremental` indicates whether the snapshot is an incremental snapshot (`true`), or a full snapshot (`false`).

```
{  
    "version": "0",  
    "id": "01234567-0123-0123-0123-012345678901",  
    "detail-type": "EBS Snapshot Notification",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "yyyy-mm-ddThh:mm:ssZ",  
    "region": "us-east-1",  
    "resources": [  
        "arn:aws:ec2::us-east-1:snapshot/snap-012345678901"  
    ],  
    "detail": {  
        "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-012345678901",  
        "source": "arn:aws:ec2::us-east-1:volume/vol-012345678901",  
        "target": "arn:aws:ec2::us-east-1:volume/vol-012345678901",  
        "status": "success",  
        "incremental": false,  
        "start_time": "2019-01-15T10:00:00Z",  
        "end_time": "2019-01-15T10:05:00Z",  
        "size_gb": 1000  
    }  
}
```

```
"region": "us-east-1",
"resources": [
    "arn:aws:ec2::us-west-2:snapshot/snap-01234567"
],
"detail": {
    "event": "copySnapshot",
    "result": "succeeded",
    "cause": "",
    "request-id": "",
    "snapshot_id": "arn:aws:ec2::us-west-2:snapshot/snap-01234567",
    "source": "arn:aws:ec2::eu-west-1:snapshot/snap-76543210",
    "startTime": "yyyy-mm-ddThh:mm:ssZ",
    "endTime": "yyyy-mm-ddThh:mm:ssZ",
    "incremental": "true"
}
```

The listing below is an example of a JSON object emitted by EBS after a failed copySnapshot event. The cause for the failure was an invalid source snapshot ID. The value of snapshot_id is the ARN of the failed snapshot. In the detail section, the value of source is the ARN of the source snapshot. startTime and endTime represent when the copy-snapshot action started and ended.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2::us-west-2:snapshot/snap-01234567"
    ],
    "detail": {
        "event": "copySnapshot",
        "result": "failed",
        "cause": "Source snapshot ID is not valid",
        "request-id": "",
        "snapshot_id": "arn:aws:ec2::us-west-2:snapshot/snap-01234567",
        "source": "arn:aws:ec2::eu-west-1:snapshot/snap-76543210",
        "startTime": "yyyy-mm-ddThh:mm:ssZ",
        "endTime": "yyyy-mm-ddThh:mm:ssZ"
    }
}
```

Share snapshot (shareSnapshot)

The shareSnapshot event is sent to your AWS account when another account shares a snapshot with it. However it is not saved, logged, or archived. The result is always succeeded.

Event data

The following is an example of a JSON object emitted by EBS after a completed shareSnapshot event. In the detail section, the value of source is the AWS account number of the user that shared the snapshot with you. startTime and endTime represent when the share-snapshot action started and ended. The shareSnapshot event is emitted only when a private snapshot is shared with another user. Sharing a public snapshot does not trigger the event.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
```

```
"source": "aws.ec2",
"account": "012345678901",
"time": "yyyy-mm-ddThh:mm:ssZ",
"region": "us-east-1",
"resources": [
    "arn:aws:ec2::us-west-2:snapshot/snap-01234567"
],
"detail": {
    "event": "shareSnapshot",
    "result": "succeeded",
    "cause": "",
    "request-id": "",
    "snapshot_id": "arn:aws:ec2::us-west-2:snapshot/snap-01234567",
    "source": 012345678901,
    "startTime": "yyyy-mm-ddThh:mm:ssZ",
    "endTime": "yyyy-mm-ddThh:mm:ssZ"
}
}
```

EBS Snapshots Archive events

Amazon EBS emits events related to snapshot archiving actions. For more information, see [Monitor snapshot archiving \(p. 1806\)](#).

EBS fast snapshot restore events

Amazon EBS sends events to EventBridge when the state of fast snapshot restore for a snapshot changes. Events are emitted on a best effort basis.

The following is example data for this event.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Fast Snapshot Restore State-change Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1::snapshot/snap-03a55cf56513fa1b6"
    ],
    "detail": {
        "snapshot-id": "snap-1234567890abcdef0",
        "state": "optimizing",
        "zone": "us-east-1a",
        "message": "Client.UserInitiated - Lifecycle state transition"
    }
}
```

The possible values for state are enabling, optimizing, enabled, disabling, and disabled.

The possible values for message are as follows:

Client.InvalidSnapshot.InvalidState - The requested snapshot transitioned to an invalid state (Error)

A request to enable fast snapshot restore failed and the state transitioned to disabling or disabled. Fast snapshot restore cannot be enabled for this snapshot.

Client.UserInitiated

The state successfully transitioned to enabling or disabling.

Client.UserInitiated - Lifecycle state transition

The state successfully transitioned to optimizing, enabled, or disabled.

Server.InsufficientCapacity - There was insufficient capacity available to satisfy the request

A request to enable fast snapshot restore failed due to insufficient capacity, and the state transitioned to disabling or disabled. Wait and then try again.

Server.InternalError - An internal error caused the operation to fail

A request to enable fast snapshot restore failed due to an internal error, and the state transitioned to disabling or disabled. Wait and then try again.

Client.InvalidSnapshot.InvalidState - The requested snapshot was deleted or access permissions were revoked

The fast snapshot restore state for the snapshot has transitioned to disabling or disabled because the snapshot was deleted or unshared by the snapshot owner. Fast snapshot restore cannot be enabled for a snapshot that has been deleted or is no longer shared with you.

Using AWS Lambda to handle EventBridge events

You can use Amazon EBS and Amazon EventBridge to automate your data-backup workflow. This requires you to create an IAM policy, a AWS Lambda function to handle the event, and an EventBridge rule that matches incoming events and routes them to the Lambda function.

The following procedure uses the `createSnapshot` event to automatically copy a completed snapshot to another Region for disaster recovery.

To copy a completed snapshot to another Region

1. Create an IAM policy, such as the one shown in the following example, to provide permissions to use the `CopySnapshot` action and write to the EventBridge log. Assign the policy to the user that will handle the EventBridge event.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "logs>CreateLogGroup",  
                "logs>CreateLogStream",  
                "logs>PutLogEvents"  
            ],  
            "Resource": "arn:aws:logs:*:*:  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ec2:CopySnapshot"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

2. Define a function in Lambda that will be available from the EventBridge console. The sample Lambda function below, written in Node.js, is invoked by EventBridge when a matching

`createSnapshot` event is emitted by Amazon EBS (signifying that a snapshot was completed). When invoked, the function copies the snapshot from us-east-2 to us-east-1.

```
// Sample Lambda function to copy an EBS snapshot to a different Region

var AWS = require('aws-sdk');
var ec2 = new AWS.EC2();

// define variables
var destinationRegion = 'us-east-1';
var sourceRegion = 'us-east-2';
console.log ('Loading function');

//main function
exports.handler = (event, context, callback) => {

    // Get the EBS snapshot ID from the event details
    var snapshotArn = event.detail.snapshot_id.split('/');
    const snapshotId = snapshotArn[1];
    const description = `Snapshot copy from ${snapshotId} in ${sourceRegion}.`;
    console.log ("snapshotId:", snapshotId);

    // Load EC2 class and update the configuration to use destination Region to
    // initiate the snapshot.
    AWS.config.update({region: destinationRegion});
    var ec2 = new AWS.EC2();

    // Prepare variables for ec2.modifySnapshotAttribute call
    const copySnapshotParams = {
        Description: description,
        DestinationRegion: destinationRegion,
        SourceRegion: sourceRegion,
        SourceSnapshotId: snapshotId
    };

    // Execute the copy snapshot and log any errors
    ec2.copySnapshot(copySnapshotParams, (err, data) => {
        if (err) {
            const errorMessage = `Error copying snapshot ${snapshotId} to Region
${destinationRegion}.`;
            console.log(errorMessage);
            console.log(err);
            callback(errorMessage);
        } else {
            const successMessage = `Successfully started copy of snapshot ${snapshotId}
to Region ${destinationRegion}.`;
            console.log(successMessage);
            console.log(data);
            callback(null, successMessage);
        }
    });
};

}
```

To ensure that your Lambda function is available from the EventBridge console, create it in the Region where the EventBridge event will occur. For more information, see the [AWS Lambda Developer Guide](#).

3. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
4. In the navigation pane, choose **Rules**, and then choose **Create rule**.
5. For **Step 1: Define rule detail**, do the following:
 - a. Enter values for **Name** and **Description**.
 - b. For **Event bus**, keep **default**.

- c. Ensure that **Enable the rule on the selected event bus** is toggled on.
 - d. For **Event type**, select **Rule with an event pattern**.
 - e. Choose **Next**.
6. For **Step 2: Build event pattern**, do the following:
 - a. For **Event source**, select **AWS events or EventBridge partner events**.
 - b. In the **Event pattern** section, for **Event source**, ensure that **AWS service** is selected, and for **AWS service**, select **EC2**.
 - c. For **Event type**, select **EBS Snapshot Notification**, select **Specific event(s)**, and then choose **createSnapshot**.
 - d. Select **Specific result(s)** and then choose **succeeded**.
 - e. Choose **Next**.
 7. For **Step 3: Select targets**, do the following:
 - a. For **Target types**, choose **AWS service**.
 - b. For **Select target**, choose **Lambda function**, and for **Function** select the function that you created earlier.
 - c. Choose **Next**.
 8. For **Step 4: Configure tags**, specify tags for the rule if needed, and then choose **Next**.
 9. For **Step 5: Review and create**, review the rule and then choose **Create rule**.

Your rule should now appear on the **Rules** tab. In the example shown, the event that you configured should be emitted by EBS the next time you copy a snapshot.

Amazon EBS quotas

To view the quotas for your Amazon EBS resources, open the Service Quotas console at <https://console.aws.amazon.com/servicequotas/>. In the navigation pane, choose **AWS services**, and select **Amazon Elastic Block Store (Amazon EBS)**.

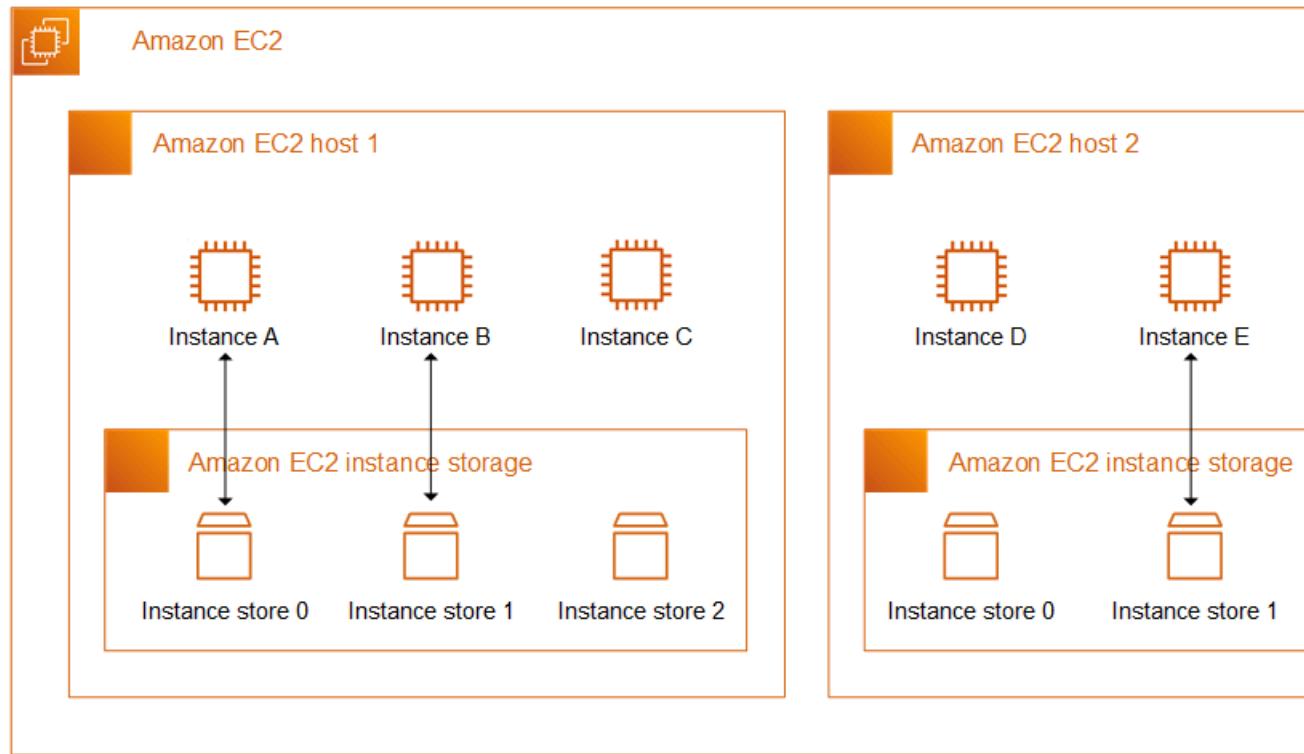

For a list of Amazon EBS service quotas, see [Amazon Elastic Block Store service quotas](#) in the AWS General Reference.

Amazon EC2 instance store

An *instance store* provides temporary block-level storage for your instance. This storage is located on disks that are physically attached to the host computer. Instance store is ideal for temporary storage of information that changes frequently, such as buffers, caches, scratch data, and other temporary content. It can also be used to store temporary data that you replicate across a fleet of instances, such as a load-balanced pool of web servers.

An instance store consists of one or more instance store volumes exposed as block devices. The size of an instance store as well as the number of devices available varies by instance type and instance size. For more information, see [Instance store volumes \(p. 1999\)](#).

The virtual devices for instance store volumes are ephemeral[0-23]. Instance types that support one instance store volume have ephemeral0. Instance types that support two or more instance store volumes have ephemeral0, ephemeral1, and so on.

Instance store pricing

Instance store volumes are included as part of the instance's usage cost.

Contents

- [Instance store volume and data lifetime \(p. 1997\)](#)

- [SSD instance store volumes \(p. 2012\)](#)

Instance store volume and data lifetime

The number, size, and type of instance store volumes are determined by the instance type and instance size. For more information, see [Instance store volumes \(p. 1999\)](#).

Instance store volumes are attached only at instance launch. You can't attach instance store volumes after launch. You can't detach an instance store volume from one instance and attach it to a different instance.

An instance store volume exists only during the lifetime of the instance to which it is attached. You can't configure an instance store volume to persist beyond the lifetime of its associated instance.

The data on an instance store volume persists even if the instance is rebooted. However, the data does not persist if the instance is stopped, hibernated, or terminated. When the instance is stopped, hibernated, or terminated, every block of the instance store volume is cryptographically erased.

Therefore, do not rely on instance store volumes for valuable, long-term data. If you need to retain the data stored on an instance store volume beyond the lifetime of the instance, you need to manually copy that data to more persistent storage, such as an Amazon EBS volume, an Amazon S3 bucket, or an Amazon EFS file system.

There are some events that can result in your data not persisting throughout the lifetime of the instance. The following table indicates whether data on instance store volumes is persisted during specific events, for both virtualized and bare metal instances.

Event	What happens to your data?
User-initiated instance lifecycle events	
The instance is rebooted (p. 612)	The data persists
The instance is stopped (p. 594)	The data does not persist
The instance is hibernated (p. 602)	The data does not persist
The instance is terminated (p. 615)	The data does not persist
The instance type is changed (p. 344)	The data does not persist *
A Windows AMI is created from the instance	The data does not persist in the created AMI **
An EBS-backed AMI is created from the instance	The data does not persist in the created AMI **
An instance store-backed AMI is created from the instance	The data persists in the AMI bundle uploaded to Amazon S3 ***
User-initiated OS events	
A shutdown is initiated	The data does not persist †
A restart is initiated	The data persists
AWS scheduled events	
Instance stop (p. 1167)	The data does not persist
Instance reboot (p. 1167)	The data persists
System reboot (p. 1167)	The data persists
Instance retirement (p. 1167)	The data does not persist
Unplanned events	
Simplified automatic recovery (p. 622)	The data does not persist
CloudWatch action based recovery (p. 624)	The data does not persist
The underlying disk fails	The data on the failed disk does not persist
Power failure	The data persists upon reboot

* If the new instance type supports instance store, the instance gets the number of instance store volumes supported by the new instance type, but the data does not transfer to the new instance. If the new instance type does not support instance store, the instance does not get the instance store volumes.

** The data is not included in the EBS-backed AMI, and it is not included on instance store volumes attached to instances launched from that AMI.

*** The data is included in the AMI bundle that is uploaded to Amazon S3. When you launch an instance from that AMI, the instance gets the instance store volumes bundled in the AMI with the data they contained at the time the AMI was created.

† Termination protection and stop protection do not protect instances against instance stops or terminations as a result of shutdowns initiated through the operating system on the instance. Data stored on instance store volumes does not persist in both instance stop and termination events.

Instance store volumes

The number, size, and type of instance store volumes are determined by the instance type and instance size. Some instance types, such as M6, C6, and R6, do not support instance store volumes, while other instance types, such as M5d, C6gd, and R6gd, do support instance store volumes. You can't attach more instance store volumes to an instance than is supported by its instance type. For the instance types that do support instance store volumes, the number and size of the instance store volumes vary by instance size. For example, m5d.1.large supports 1 x 75 GB instance store volume, while m5d.24xlarge supports 4 x 900 GB instance store volumes.

For instance types with **NVMe instance store volumes**, all of the supported instance store volumes are automatically attached to the instance at launch. For instance types with **non-NVMe instance store volumes**, such as C1, C3, M1, M2, M3, R3, D2, H1, I2, G2, X1, and X1e, you must manually specify the block device mappings for the instance store volumes that you want to attach at launch. Then, after the instance has launched, you must [format and mount the attached instance store volumes \(p. 2011\)](#) before you can use them. You can't attach an instance store volume after you launch the instance.

Some instance types use NVMe or SATA-based solid state drives (SSD), while others use SATA-based hard disk drives (HDD). SSDs deliver high random I/O performance with very low latency, but you don't need the data to persist when the instance terminates or you can take advantage of fault-tolerant architectures. For more information, see [SSD instance store volumes \(p. 2012\)](#).

The data on NVMe instance store volumes and some HDD instance store volumes is encrypted at rest. For more information, see [Data protection in Amazon EC2 \(p. 1581\)](#).

Available instance store volumes

The following table provides the quantity, size, type, and performance optimizations of instance store volumes available on each supported instance type.

Instance store volume performance

The following documentation describes the I/O performance of the instance store volumes.

- [General purpose instances \(p. 242\)](#)
- [Compute optimized instances \(p. 289\)](#)
- [Memory optimized instances \(p. 309\)](#)
- [Storage optimized instances \(p. 319\)](#)
- [Accelerated computing instances \(p. 327\)](#)

To query instance store volume information using the AWS CLI

You can use the [describe-instance-types](#) AWS CLI command to display information about an instance type, such as its instance store volumes. The following example displays the total size of instance storage for all R5 instances with instance store volumes.

```
aws ec2 describe-instance-types \
  --filters "Name=instance-type,Values=r5*" "Name=instance-storage-supported,Values=true"
  \
  --query "InstanceTypes[].[InstanceType, InstanceStorageInfo.TotalSizeInGB]" \
  --output table
```

Example output

DescribeInstanceTypes	
r5ad.24xlarge	3600
r5ad.12xlarge	1800
r5dn.8xlarge	1200
r5ad.8xlarge	1200
r5ad.large	75
r5d.4xlarge	600

.	.	.
r5dn.2xlarge 300		
r5d.12xlarge 1800		

The following example displays the complete instance storage details for the specified instance type.

```
aws ec2 describe-instance-types \
--filters "Name=instance-type,Values=r5d.4xlarge" \
--query "InstanceTypes[0].InstanceStorageInfo"
```

The example output shows that this instance type has two 300 GB NVMe SSD volumes, for a total of 600 GB of instance storage.

```
[  
  {  
    "TotalSizeInGB": 600,  
    "Disks": [  
      {  
        "SizeInGB": 300,  
        "Count": 2,  
        "Type": "ssd"  
      }  
    ],  
    "NvmeSupport": "required"  
  }  
]
```

Add instance store volumes to your EC2 instance

For instance types with **NVMe instance store volumes**, all of the supported instance store volumes are automatically attached to the instance at launch. They are automatically enumerated and assigned a device name on instance launch.

For instance types with **non-NVMe instance store volumes**, such as C1, C3, M1, M2, M3, R3, D2, H1, I2, G2, X1, and X1e, you must manually specify the block device mappings for the instance store volumes that you want to attach at launch. Block device mappings can be specified in the instance launch request or in the AMI used to launch the instance. The block device mapping includes a device name and the volume that it maps to. For more information, see [Block device mappings \(p. 2026\)](#)

Important

Instance store volumes can be attached to an instance only when you launch it. You can't attach instance store volumes to an instance after you've launched it.

After you launch an instance, you must ensure that the instance store volumes for your instance are formatted and mounted before you can use them. The root volume of an instance store-backed instance is mounted automatically.

Consideration for root volumes

A block device mapping always specifies the root volume for the instance. The root volume is mounted automatically. For Windows instances, the root volume must be an Amazon EBS volume; instance store is not supported for the root volume.

Contents

- [Add instance store volumes to an AMI \(p. 2010\)](#)
- [Add non-NVME instance store volumes to an instance \(p. 2010\)](#)
- [Make instance store volumes available on your instance \(p. 2011\)](#)

Add instance store volumes to an AMI

You can create an AMI with a block device mapping that includes instance store volumes.

If you launch an instance that supports **non-NVMe instance store volumes** using an AMI that specifies instance store volume block device mappings, the instance includes the instance store volumes. If the number of instance store volume block device mappings in the AMI exceeds the number of instance store volumes available to the instance, the additional instance store volume block device mappings are ignored.

If you launch an instance that supports **NVMe instance store volumes** using an AMI that specifies instance store volume block device mappings, the instance store volume block device mappings are ignored. Instances that support NVMe instance store volumes get all of their supported instance store volumes, regardless of the block device mappings specified in the instance launch request and the AMI.

Considerations

- For M3 instances, specify instance store volumes in the block device mapping of the instance, not the AMI. Amazon EC2 might ignore instance store volume block device mappings in the AMI.
- When you launch an instance, you can omit non-NVMe instance store volumes specified in the AMI block device mapping or add instance store volumes.

New console

To add instance store volumes to an Amazon EBS-backed AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the instance.
3. Choose **Actions, Image and templates, Create image**.
4. On the **Create image** page, enter a meaningful name and description for your image.
5. For each instance store volume to add, choose **Add volume**, from **Volume type** select an instance store volume, and from **Device** select a device name. (For more information, see [Device names on Windows instances \(p. 2024\)](#).) The number of available instance store volumes depends on the instance type. For instances with NVMe instance store volumes, the device mapping of these volumes depends on the order in which the operating system enumerates the volumes.
6. Choose **Create image**.

AWS CLI

To add instance store volumes to an AMI using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [create-image](#) or [register-image](#) (AWS CLI)
- [New-EC2Image](#) and [Register-EC2Image](#) (AWS Tools for Windows PowerShell)

Add non-NVME instance store volumes to an instance

When you launch an instance that supports **non-NVMe instance store volumes** you must specify block device mappings for the instance store volumes to attach. The block device mappings must be specified in the instance launch request or in the AMI used to launch the instance.

If the AMI includes block device mappings for the instance store volumes, you do not need to specify block device mappings in the instance launch request, unless you need more instance store volumes than is included in the AMI.

If the AMI does not include block device mappings for instance store volumes, then you must specify the block device mappings in the instance launch request.

Considerations

- For M3 instances, you might receive instance store volumes even if you do not specify them in the block device mapping for the instance.

To specify block device mappings in the instance launch request, use one of the following methods.

Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the dashboard, choose **Launch instance**.
3. In the **Application and OS Images** section, select the AMI to use.
4. In the **Configure storage** section, the **Instance store volumes** section lists the instance store volumes that can be attached to the instance. The number of available instance store volumes depends on the instance type.
5. For each instance store volume to attach, for **Device name**, select the device name to use.
6. Configure the remaining instance settings as needed, and then choose **Launch instance**.

Command line

You can use one of the following options commands with the corresponding option.

- `--block-device-mappings` with [run-instances](#) (AWS CLI)
- `-BlockDeviceMapping` with [New-EC2Instance](#) (AWS Tools for Windows PowerShell)

Make instance store volumes available on your instance

After you launch an instance with attached instance store volumes, you must mount the volumes before you can access them.

For Linux instances, many instance store volumes are pre-formatted with the ext3 file system. SSD-based instance store volumes that support TRIM instruction are not pre-formatted with any file system. However, you can format volumes with the file system of your choice after you launch your instance. For more information, see [Instance store volume TRIM support \(p. 2013\)](#). For Windows instances, we reformat the instance store volumes with the NTFS file system.

You can confirm that the instance store devices are available from within the instance itself using instance metadata. For more information, see [View the instance block device mapping for instance store volumes \(p. 2034\)](#).

For Windows instances, you can also view the instance store volumes using Windows Disk Management. For more information, see [List disks using Disk Management \(p. 2039\)](#).

To manually mount an instance store volume

1. Choose **Start**, enter **Computer Management**, and then press **Enter**.
2. In left-hand panel, choose **Disk Management**.

3. If you are prompted to initialize the volume, choose the volume to initialize, select the required partition type depending on your use case, and then choose **OK**.
4. In the list of volumes, right-click the volume to mount, and then choose **New Simple Volume**.
5. On the wizard, choose **Next**.
6. On the Specify Volume Size screen, choose **Next** to use the maximum volume size. Alternatively, choose a volume size that is between the minimum and maximum disk space.
7. On the Assign a Drive Letter or Path screen, do one of the following, and choose **Next**.
 - To mount the volume with a drive letter, choose **Assign the following drive letter** and then choose the drive letter to use.
 - To mount the volume as a folder, choose **Mount in the following empty NTFS folder** and then choose **Browse** to create or select the folder to use.
 - To mount the volume without a drive letter or path, choose **Do not assign a drive letter or drive path**.
8. On the Format Partition screen, specify whether or not to format the volume. If you choose to format the volume, choose the required file system and unit size, and specify a volume label.
9. Choose **Next, Finish**.

SSD instance store volumes

Like other instance store volumes, you must map the SSD instance store volumes for your instance when you launch it. The data on an SSD instance volume persists only for the life of its associated instance. For more information, see [Add instance store volumes to your EC2 instance \(p. 2009\)](#).

NVMe SSD volumes

Some instances offer non-volatile memory express (NVMe) solid state drives (SSD) instance store volumes. For more information about the type of instance store volume supported by each instance type, see [Instance store volumes \(p. 1999\)](#).

The latest AWS Windows AMIs for the following operating systems contain the AWS NVMe drivers used to interact with SSD instance store volumes that are exposed as NVMe block devices for better performance:

- Windows Server 2019
- Windows Server 2016
- Windows Server 2012 R2
- Windows Server 2012
- Windows Server 2008 R2

After you connect to your instance, you can verify that you see the NVMe volumes in Disk Manager. On the taskbar, open the context (right-click) menu for the Windows logo and choose **Disk Management**. On Windows Server 2008 R2, choose **Start, Administrative Tools, Computer Management, Disk Management**.

The AWS Windows AMIs provided by Amazon include the AWS NVMe driver. If you are not using the latest AWS Windows AMIs, you can [install the current AWS NVMe driver \(p. 799\)](#).

The data on NVMe instance storage is encrypted using an XTS-AES-256 block cipher implemented in a hardware module on the instance. The encryption keys are generated using the hardware module and are unique to each NVMe instance storage device. All encryption keys are destroyed when the instance

is stopped or terminated and cannot be recovered. You cannot disable this encryption and you cannot provide your own encryption key.

Non-NVMe SSD volumes

The following instances support instance store volumes that use non-NVMe SSDs to deliver high random I/O performance: C3, G2, I2, M3, R3, and X1. For more information about the instance store volumes supported by each instance type, see [Instance store volumes \(p. 1999\)](#).

Instance store volume TRIM support

Some instance types support SSD volumes with TRIM. For more information, see [Instance store volumes \(p. 1999\)](#).

Instances running Windows Server 2012 R2 support TRIM as of AWS PV Driver version 7.3.0. Instances running earlier versions of Windows Server do not support TRIM.

Instance store volumes that support TRIM are fully trimmed before they are allocated to your instance. These volumes are not formatted with a file system when an instance launches, so you must format them before they can be mounted and used. For faster access to these volumes, you should skip the TRIM operation when you format them. On Windows, to temporarily disable TRIM support during initial formatting, use the `fsutil behavior set DisableDeleteNotify 1` command. After formatting is complete, re-enable TRIM support by using `fsutil behavior set DisableDeleteNotify 0`.

With instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller when you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. On Windows, use the `fsutil behavior set DisableDeleteNotify 0` command to ensure TRIM support is enabled during normal operation.

File storage

Cloud file storage is a method for storing data in the cloud that provides servers and applications access to data through shared file systems. This compatibility makes cloud file storage ideal for workloads that rely on shared file systems and provides simple integration without code changes.

There are many file storage solutions that exist, ranging from a single node file server on a compute instance using block storage as the underpinnings with no scalability or few redundancies to protect the data, to a do-it-yourself clustered solution, to a fully-managed solution. The following content introduces some of the storage services provided by AWS for use with Windows.

Contents

- [Use Amazon S3 with Amazon EC2 \(p. 2013\)](#)
- [Use Amazon EFS with Amazon EC2 \(p. 2015\)](#)
- [Use Amazon FSx with Amazon EC2 \(p. 2015\)](#)

Use Amazon S3 with Amazon EC2

Amazon S3 is a repository for internet data. Amazon S3 provides access to reliable, fast, and inexpensive data storage infrastructure. It is designed to make web-scale computing easier by enabling you to store and retrieve any amount of data, at any time, from within Amazon EC2 or anywhere on the web. Amazon S3 stores data objects redundantly on multiple devices across multiple facilities and allows concurrent

read or write access to these data objects by many separate clients or application threads. You can use the redundant data stored in Amazon S3 to recover quickly and reliably from instance or application failures.

Amazon EC2 uses Amazon S3 for storing Amazon Machine Images (AMIs). You use AMIs for launching EC2 instances. In case of instance failure, you can use the stored AMI to immediately launch another instance, thereby allowing for fast recovery and business continuity.

Amazon EC2 also uses Amazon S3 to store snapshots (backup copies) of the data volumes. You can use snapshots for recovering data quickly and reliably in case of application or system failures. You can also use snapshots as a baseline to create multiple new data volumes, expand the size of an existing data volume, or move data volumes across multiple Availability Zones, thereby making your data usage highly scalable. For more information about using data volumes and snapshots, see [Amazon Elastic Block Store \(p. 1702\)](#).

Objects are the fundamental entities stored in Amazon S3. Every object stored in Amazon S3 is contained in a bucket. Buckets organize the Amazon S3 namespace at the highest level and identify the account responsible for that storage. Amazon S3 buckets are similar to internet domain names. Objects stored in the buckets have a unique key value and are retrieved using a URL. For example, if an object with a key value /photos/mygarden.jpg is stored in the *DOC-EXAMPLE-BUCKET1* bucket, then it is addressable using the URL <https://DOC-EXAMPLE-BUCKET1.s3.amazonaws.com/photos/mygarden.jpg>.

For more information about the features of Amazon S3, see the [Amazon S3 product page](#).

Usage examples

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](#).

Given the benefits of Amazon S3 for storage, you might decide to use this service to store files and data sets for use with EC2 instances. There are several ways to move data to and from Amazon S3 to your instances. In addition to the examples discussed below, there are a variety of tools that people have written that you can use to access your data in Amazon S3 from your computer or your instance. Some of the common ones are discussed in the AWS forums.

If you have permission, you can copy a file to or from Amazon S3 and your instance using one of the following methods.

AWS Tools for Windows PowerShell

Windows instances have the benefit of a graphical browser that you can use to access the Amazon S3 console directly; however, for scripting purposes, Windows users can also use the [AWS Tools for Windows PowerShell](#) to move objects to and from Amazon S3.

Use the following command to copy an Amazon S3 object to your Windows instance.

```
PS C:\> Copy-S3Object -BucketName my_bucket -Key path-to-file -LocalFile my_copied_file.ext
```

AWS Command Line Interface

The AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. The AWS CLI enables users to authenticate themselves and download restricted items from Amazon S3 and also to upload items. For more information, such as how to install and configure the tools, see the [AWS Command Line Interface detail page](#).

The **aws s3 cp** command is similar to the Unix **cp** command. You can copy files from Amazon S3 to your instance, copy files from your instance to Amazon S3, and copy files from one Amazon S3 location to another.

Use the following command to copy an object from Amazon S3 to your instance.

```
aws s3 cp s3://my_bucket/my_folder/my_file.ext my_copied_file.ext
```

Use the following command to copy an object from your instance back into Amazon S3.

```
aws s3 cp my_copied_file.ext s3://my_bucket/my_folder/my_file.ext
```

The **aws s3 sync** command can synchronize an entire Amazon S3 bucket to a local directory location. This can be helpful for downloading a data set and keeping the local copy up-to-date with the remote set. If you have the proper permissions on the Amazon S3 bucket, you can push your local directory back up to the cloud when you are finished by reversing the source and destination locations in the command.

Use the following command to download an entire Amazon S3 bucket to a local directory on your instance.

```
aws s3 sync s3://remote_S3_bucket local_directory
```

Amazon S3 API

If you are a developer, you can use an API to access data in Amazon S3. For more information, see the [Amazon Simple Storage Service User Guide](#). You can use this API and its examples to help develop your application and integrate it with other APIs and SDKs, such as the boto Python interface.

Use Amazon EFS with Amazon EC2

Amazon EFS provides scalable file storage for use with Amazon EC2. You can use an EFS file system as a common data source for workloads and applications running on multiple instances. For more information, see the [Amazon Elastic File System product page](#).

Important

Amazon EFS is not supported on Windows instances. To use Amazon EFS with a Linux instance, see [Amazon Elastic File System \(Amazon EFS\)](#) in the [Amazon EC2 User Guide for Linux Instances](#).

Use Amazon FSx with Amazon EC2

The Amazon FSx family of services makes it easy to launch, run, and scale shared storage powered by popular commercial and open-source file systems. You can use the *new launch instance wizard* to automatically attach the following types of Amazon FSx file systems to your Amazon EC2 instances at launch:

- Amazon FSx for NetApp ONTAP provides fully managed shared storage in the AWS Cloud with the popular data access and management capabilities of NetApp ONTAP.
- Amazon FSx for OpenZFS provides fully managed cost-effective shared storage powered by the popular OpenZFS file system.

Note

- This functionality is available in the new launch instance wizard only. For more information, see [Launch an instance using the new launch instance wizard \(p. 552\)](#)

- Amazon FSx for Windows File Server and Amazon FSx for Lustre file systems can't be mounted at launch. You must mount these file systems manually after launch.

You can choose to mount an existing file system that you created previously, or you can create a new file system to mount to an instance at launch.

Topics

- [Security groups and user data script \(p. 2016\)](#)
- [Mount an Amazon FSx file system at launch \(p. 2018\)](#)

Security groups and user data script

When you mount an Amazon FSx file system to an instance using the launch instance wizard, you can choose whether to automatically create and attach the security groups needed to enable access to the file system, and whether to automatically include the user data scripts needed to mount the file system and make it available for use.

Topics

- [Security groups \(p. 2016\)](#)
- [User data script \(p. 2017\)](#)

Security groups

If you choose to automatically create the security groups that are needed to enable access to the file system, the launch instance wizard creates and attaches two security groups - one security group is attached to the instance, and the other is attached to the file system. For more information about the security group requirements, see [FSx for ONTAP file system access control with Amazon VPC](#) and [FSx for OpenZFS file system access control with Amazon VPC](#).

We add the tag Name=instance-sg-*1* to the security group that is created and attached to the instance. The value in the tag is automatically incremented each time the launch instance wizard creates a security group for Amazon FSx file systems.

The security group includes the following output rules, but no inbound rules.

Outbound rules

Protocol type	Port number	Destination
UDP	111	<i>file system security group</i>
UDP	20001 - 20003	<i>file system security group</i>
UDP	4049	<i>file system security group</i>
UDP	2049	<i>file system security group</i>
UDP	635	<i>file system security group</i>
UDP	4045 - 4046	<i>file system security group</i>
TCP	4049	<i>file system security group</i>
TCP	635	<i>file system security group</i>
TCP	2049	<i>file system security group</i>

Protocol type	Port number	Destination
TCP	111	<i>file system security group</i>
TCP	4045 - 4046	<i>file system security group</i>
TCP	20001 - 20003	<i>file system security group</i>
All	All	<i>file system security group</i>

The security group that is created and attached to the file system is tagged with Name=fsx-sg-**1**. The value in the tag is automatically incremented each time the launch instance wizard creates a security group for Amazon FSx file systems.

The security group includes the following rules.

Inbound rules

Protocol type	Port number	Source
UDP	2049	<i>instance security group</i>
UDP	20001 - 20003	<i>instance security group</i>
UDP	4049	<i>instance security group</i>
UDP	111	<i>instance security group</i>
UDP	635	<i>instance security group</i>
UDP	4045 - 4046	<i>instance security group</i>
TCP	4045 - 4046	<i>instance security group</i>
TCP	635	<i>instance security group</i>
TCP	2049	<i>instance security group</i>
TCP	4049	<i>instance security group</i>
TCP	20001 - 20003	<i>instance security group</i>
TCP	111	<i>instance security group</i>

Outbound rules

Protocol type	Port number	Destination
All	All	0.0.0.0/0

User data script

If you choose to automatically attach user data scripts, the launch instance wizard adds the following user data to the instance. This script installs the necessary packages, mounts the file system, and updates your instance settings so that the file system will automatically re-mount whenever the instance restarts.

```
#cloud-config
```

```
package_update: true
package_upgrade: true
runcmd:
- yum install -y nfs-utils
- apt-get -y install nfs-common
- svm_id_1=svm_id
- file_system_id_1=file_system_id
- vol_path_1=/vol1
- fsx_mount_point_1=/mnt/fsx/fs1
- mkdir -p "${fsx_mount_point_1}"
- if [ -z "$svm_id_1" ]; then printf "\n${file_system_id_1}.fsx.eu-  
north-1.amazonaws.com:${vol_path_1} ${fsx_mount_point_1} nfs4  
nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeout=600,retrans=2,noresvport,_netdev  
0 0\n" >> /etc/fstab; else printf "\n${svm_id_1}.${file_system_id_1}.fsx.eu-  
north-1.amazonaws.com:${vol_path_1} ${fsx_mount_point_1} nfs4  
nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeout=600,retrans=2,noresvport,_netdev 0 0\n"  
>> /etc/fstab; fi
- retryCnt=15; waitTime=30; while true; do mount -a -t nfs4 defaults; if [ $? = 0 ] ||  
[ $retryCnt -lt 1 ]; then echo File system mounted successfully; break; fi; echo File  
system not available, retrying to mount.; ((retryCnt--)); sleep $waitTime; done;
```

Mount an Amazon FSx file system at launch

To mount a new or existing Amazon FSx file system at launch

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and then choose **Launch instance** to open the launch instance wizard.
3. In the **Application and OS Images** section, select the AMI to use.
4. In the **Instance type** section, select the instance type.
5. In the **Key pair** section, select an existing key pair or create a new one.
6. In the **Network settings** section, do the following:
 - a. Choose **Edit**.
 - b. If you want to **mount an existing file system**, for **Subnet**, choose the file system's preferred subnet. We recommend that you launch the instance into the same Availability Zone as the file system's preferred subnet to optimize performance.

If you want to **create a new file system** to mount to an instance, for **Subnet**, choose the subnet into which to launch the instance.

Important

You must select a subnet to enable the Amazon FSx functionality in the new launch instance wizard. If you do not select a subnet, you will not be able to mount an existing file system or create a new one.

7. In the **Storage** section, do the following:
 - a. Configure the volumes as needed.
 - b. Expand the **File systems** section and select **FSx**.
 - c. Choose **Add shared file system**.
 - d. For **File system**, select the file system to mount.

Note

The list displays all Amazon FSx for NetApp ONTAP and Amazon FSx for OpenZFS file systems in your account in the selected Region.

- e. To automatically create and attach the security groups needed to enable access to the file system, select **Automatically create and attach security groups**. If you prefer to create

- the security groups manually, clear the check box. For more information, see [Security groups \(p. 2016\)](#).
- f. To automatically attach the user data scripts needed to mount the file system, select **Automatically mount shared file system by attaching required user data script**. If you prefer to provide the user data scripts manually, clear the check box. For more information, see [User data script \(p. 2017\)](#).
 8. In the **Advanced** section, configure the additional instance settings as needed.
 9. Choose **Launch**.

Instance volume limits

The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. When considering how many volumes to attach to your instance, you should consider whether you need increased I/O bandwidth or increased storage capacity.

Bandwidth versus capacity

For consistent and predictable bandwidth use cases, use [Amazon EBS-optimized instances \(p. 1941\)](#) with [General Purpose SSD volumes \(p. 1710\)](#) or [Provisioned IOPS SSD volumes \(p. 1713\)](#). For maximum performance, match the IOPS you have provisioned for your volumes with the bandwidth available for your instance type.

For RAID configurations, you might find that arrays larger than 8 volumes have diminished performance returns due to increased I/O overhead. Test your individual application performance and tune it as required.

Topics

- [Volume limits for instances built on the Nitro System \(p. 2019\)](#)
- [Volume limits for Xen-based instances \(p. 2020\)](#)

Volume limits for instances built on the Nitro System

Dedicated Amazon EBS volume limit

The following Nitro instance types have a dedicated Amazon EBS volume limit of up to 128 attachments, depending on instance size. The limit is not shared with other device attachments. In other words, you can attach any number of Amazon EBS volumes up to the volume attachment limit, regardless of the number of attached devices, such as NVMe instance store volumes and network interfaces.

- General purpose: M7i, M7a

The volume limits depend on the instance size. The following table shows the limit for each instance size.

Instance size	Volume limit
medium large xlarge 2xlarge 4xlarge 8xlarge 12xlarge	32
16xlarge	48
24xlarge	64
32xlarge	88

Instance size	Volume limit
48xlarge	128
metal-48x1	79

Shared Amazon EBS volume limit

All other Nitro instance types have a volume attachment limit that is shared between Amazon EBS volumes, network interfaces, and NVMe instance store volumes. You can attach any number of Amazon EBS volumes up to that limit, less the number of attached network interfaces and NVMe instance store volumes. Keep in mind that every instance must have at least one network interface, and that NVMe instance store volumes are automatically attached at launch.

Most of these instances support a maximum of 28 attachments. For example, if you have no additional network interface attachments on an m5.xlarge instance, you can attach up to 27 EBS volumes (*28 volume limit - 1 network interface*). If you have two additional network interfaces on an m5.xlarge instance, you can attach up to 25 EBS volumes (*28 volume limit - 3 network interfaces*). Similarly, if you have two additional network interfaces on an m5d.xlarge instance, which has 1 NVMe instance store volume, you can attach up to 24 EBS volumes (*28 volume limit - 3 network interfaces - 1 NVMe instance store volume*).

The following exceptions apply:

- Most bare metal instances support a maximum of 31 EBS volumes.
- High memory virtualized instances support a maximum of 27 EBS volumes.
- High memory bare metal instances support a maximum of 19 EBS volumes.
- mac1.metal instances support a maximum of 16 EBS volumes.
- inf1.24xlarge instances support a maximum of 11 EBS volumes.
- g5.48xlarge instances support a maximum of 9 EBS volumes.
- d3.8xlarge and d3en.12xlarge instances support a maximum of 3 EBS volumes.
- For accelerated computing instances, the attached accelerators count towards the shared volume limit. For example, for p4d.24xlarge instances, which have a shared volume limit of 28, 8 GPUs, and 8 NVMe instance store volumes, you can attach up to 11 Amazon EBS volumes (*28 volume limit - 1 network interface - 8 GPUs - 8 NVMe instance store volumes*).

Volume limits for Xen-based instances

The following table shows the volume limits for Xen-based Windows instances based on the driver used. That these numbers include the root volume, plus any attached instance store volumes and Amazon EBS volumes.

Important

Attaching more than the following number of volumes to a Xen-based Windows instance is supported on a best effort basis only and is not guaranteed.

Driver	Volume Limit
AWS PV	26
Citrix PV	26
Red Hat PV	17

We recommend that you do not attach more than 26 volumes to a Xen-based Windows instance with AWS PV or Citrix PV drivers, as it is likely to cause performance issues.

To determine which PV drivers your instance is using, or to upgrade your Windows instance from Red Hat to Citrix PV drivers, see [Upgrade PV drivers on Windows instances \(p. 786\)](#).

For more information about how device names are related to volumes, see [Map disks to volumes on your Windows instance \(p. 2035\)](#).

Amazon EC2 instance root device volume

When you launch an instance, the *root device volume* contains the image used to boot the instance. When you launch a Windows instance, a root EBS volume is created from an EBS snapshot and attached to the instance.

Topics

- [Configure the root volume to persist \(p. 2021\)](#)
- [Confirm that a root volume is configured to persist \(p. 2023\)](#)
- [Change the initial size of the root volume \(p. 2024\)](#)

Configure the root volume to persist

By default, the root volume is deleted when the instance terminates (the `DeleteOnTermination` attribute is `true`). Using the console, you can change `DeleteOnTermination` when you launch an instance. To change this attribute for an existing instance, you must use the command line.

Topics

- [Configure the root volume to persist during instance launch \(p. 2021\)](#)
- [Configure the root volume to persist for an existing instance \(p. 2022\)](#)

Configure the root volume to persist during instance launch

You can configure the root volume to persist when you launch an instance using the Amazon EC2 console or the command line tools.

Console

To configure the root volume to persist when you launch an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and then choose **Launch instances**.
3. On the **Choose an Amazon Machine Image (AMI)** page, select the AMI to use and choose **Select**.
4. Follow the wizard to complete the **Choose an Instance Type** and **Configure Instance Details** pages.
5. On the **Add Storage** page, deselect **Delete On Termination** for the root volume.
6. Complete the remaining wizard pages, and then choose **Launch**.

AWS CLI

To configure the root volume to persist when you launch an instance using the AWS CLI

Use the [run-instances](#) command and include a block device mapping that sets the DeleteOnTermination attribute to false.

```
C:\> aws ec2 run-instances --block-device-mappings file://mapping.json ...other parameters...
```

Specify the following in mapping.json.

```
[  
  {  
    "DeviceName": "/dev/sda1",  
    "Ebs": {  
      "DeleteOnTermination": false  
    }  
  }  
]
```

Tools for Windows PowerShell

To configure the root volume to persist when you launch an instance using the Tools for Windows PowerShell

Use the [New-EC2Instance](#) command and include a block device mapping that sets the DeleteOnTermination attribute to false.

```
C:\> $ebs = New-Object Amazon.EC2.Model.EbsBlockDevice  
C:\> $ebs.DeleteOnTermination = $false  
C:\> $bdm = New-Object Amazon.EC2.Model.BlockDeviceMapping  
C:\> $bdm.DeviceName = "dev/xvda"  
C:\> $bdm.Ebs = $ebs  
C:\> New-EC2Instance -ImageId ami-0abcdef1234567890 -BlockDeviceMapping $bdm ...other parameters...
```

Configure the root volume to persist for an existing instance

You can configure the root volume to persist for a running instance using the command line tools only.

AWS CLI

To configure the root volume to persist for an existing instance using the AWS CLI

Use the [modify-instance-attribute](#) command with a block device mapping that sets the DeleteOnTermination attribute to false.

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --block-device-mappings file://mapping.json
```

Specify the following in mapping.json.

```
[  
  {  
    "DeviceName": "/dev/xvda",  
    "Ebs": {  
      "DeleteOnTermination": false  
    }  
  }  
]
```

]

Tools for Windows PowerShell

To configure the root volume to persist for an existing instance using the AWS Tools for Windows PowerShell

Use the [Edit-EC2InstanceAttribute](#) command with a block device mapping that sets the DeleteOnTermination attribute to false.

```
C:\> $ebs = New-Object Amazon.EC2.Model.EbsInstanceBlockDeviceSpecification
C:\> $ebs.DeleteOnTermination = $false
C:\> $bdm = New-Object Amazon.EC2.Model.InstanceBlockDeviceMappingSpecification
C:\> $bdm.DeviceName = "/dev/xvda"
C:\> $bdm.Ebs = $ebs
C:\> Edit-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -BlockDeviceMapping $bdm
```

Confirm that a root volume is configured to persist

You can confirm that a root volume is configured to persist using the Amazon EC2 console or the command line tools.

New console

To confirm that a root volume is configured to persist using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and then select the instance.
3. In the **Storage** tab, under **Block devices**, locate the entry for the root volume. If **Delete on termination** is No, the volume is configured to persist.

Old console

To confirm that a root volume is configured to persist using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and then select the instance.
3. In the **Description** tab, choose the entry for **Root device**. If **Delete on termination** is False, the volume is configured to persist.

AWS CLI

To confirm that a root volume is configured to persist using the AWS CLI

Use the [describe-instances](#) command and verify that the DeleteOnTermination attribute in the BlockDeviceMappings response element is set to false.

```
C:\> aws ec2 describe-instances --instance-id i-1234567890abcdef0
```

```
...
"BlockDeviceMappings": [
{
```

```
"DeviceName": "/dev/sda1",
"Ebs": {
    "Status": "attached",
    "DeleteOnTermination": false,
    "VolumeId": "vol-1234567890abcdef0",
    "AttachTime": "2013-07-19T02:42:39.000Z"
}
...
...
```

Tools for Windows PowerShell

To confirm that a root volume is configured to persist using the AWS Tools for Windows PowerShell

Use the [Get-EC2Instance](#) and verify that the DeleteOnTermination attribute in the BlockDeviceMappings response element is set to false.

```
C:\> (Get-EC2Instance -InstanceId i-i-1234567890abcdef0).Instances.BlockDeviceMappings.Ebs
```

Change the initial size of the root volume

By default, the size of the root volume is determined by the size of the snapshot. You can increase the initial size of the root volume using the block device mapping of the instance as follows.

1. Determine the device name of the root volume specified in the AMI, as described in [View the EBS volumes in an AMI block device mapping \(p. 2030\)](#).
2. Confirm the size of the snapshot specified in the AMI block device mapping, as described in [View Amazon EBS snapshot information \(p. 1809\)](#).
3. Override the size of the root volume using the instance block device mapping, as described in [Update the block device mapping when launching an instance \(p. 2031\)](#), specifying a volume size that is larger than the snapshot size.

For example, the following entry for the instance block device mapping increases the size of the root volume, /dev/xvda, to 100 GiB. You can omit the snapshot ID in the instance block device mapping because the snapshot ID is already specified in the AMI block device mapping.

```
{
    "DeviceName": "/dev/xvda",
    "Ebs": {
        "VolumeSize": 100
    }
}
```

For more information, see [Block device mappings \(p. 2026\)](#).

Device names on Windows instances

When you attach a volume to your instance, you include a device name for the volume. This device name is used by Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume, and the name assigned can be different from the name that Amazon EC2 uses.

The number of volumes that your instance can support is determined by the operating system. For more information, see [Instance volume limits \(p. 2019\)](#).

Contents

- [Available device names \(p. 2025\)](#)
- [Device name considerations \(p. 2025\)](#)

For information about device names on Linux instances, see [Device naming on Linux instances](#) in the *Amazon EC2 User Guide for Linux Instances*.

Available device names

Windows AMIs use one of the following sets of drivers to permit access to virtualized hardware: AWS PV, Citrix PV, and RedHat PV. For more information, see [Paravirtual drivers for Windows instances \(p. 780\)](#).

The following table lists the available device names that you can specify in a block device mapping or when attaching an EBS volume.

Driver type	Available	Reserved for root volume	Recommended for EBS volumes	Instance store volumes
AWS PV, Citrix PV	xvd[b-z] xvd[b-c][a-z] /dev/sda1 /dev/sd[b-e]	/dev/sda1	xvd[f-z] * **	xvdc[a-x] xvd[a-e]
Red Hat PV	xvd[a-z] xvd[b-c][a-z] /dev/sda1 /dev/sd[b-e]	/dev/sda1	xvd[f-p]	xvdc[a-x] xvd[a-e]

* For Citrix PV and Red Hat PV, if you map an EBS volume with the name xvda, Windows does not recognize the volume (the volume is visible for AWS PV or AWS NVMe).

** NVMe instance store volumes are automatically enumerated and assigned a Windows drive letter.

For more information about instance store volumes, see [Amazon EC2 instance store \(p. 1996\)](#). For more information about NVMe EBS volumes (Nitro-based instances), including how to identify the EBS device, see [Amazon EBS and NVMe on Windows instances \(p. 1939\)](#).

Device name considerations

Keep the following in mind when selecting a device name:

- Although you can attach your EBS volumes using the device names used to attach instance store volumes, we strongly recommend that you don't because the behavior can be unpredictable.
- The number of NVMe instance store volumes for an instance depends on the size of the instance. NVMe instance store volumes are automatically enumerated and assigned a Windows drive letter.

- AWS Windows AMIs come with additional software that prepares an instance when it first boots up. This is either the EC2Config service (Windows AMIs prior to Windows Server 2016) or EC2Launch (Windows Server 2016 and later). After the devices have been mapped to drives, they are initialized and mounted. The root drive is initialized and mounted as C:\. By default, when an EBS volume is attached to a Windows instance, it can show up as any drive letter on the instance. You can change the settings to set the drive letters of the volumes per your specifications. For instance store volumes, the default depends on the driver. AWS PV drivers and Citrix PV drivers assign instance store volumes drive letters going from Z: to A:. Red Hat drivers assign instance store volumes drive letters going from D: to Z:. For more information, see [Configure a Windows instance using the EC2Config service \(p. 753\)](#), [Configure a Windows instance using EC2Launch \(p. 743\)](#), and [Map disks to volumes on your Windows instance \(p. 2035\)](#).

Block device mappings

Each instance that you launch has an associated root device volume, which is either an Amazon EBS volume or an instance store volume. You can use block device mapping to specify additional EBS volumes or instance store volumes to attach to an instance when it's launched. You can also attach additional EBS volumes to a running instance; see [Attach an Amazon EBS volume to an instance \(p. 1729\)](#). However, the only way to attach instance store volumes to an instance is to use block device mapping to attach the volumes as the instance is launched.

For more information about root device volumes, see [Amazon EC2 instance root device volume \(p. 2021\)](#).

Contents

- [Block device mapping concepts \(p. 2026\)](#)
- [AMI block device mapping \(p. 2029\)](#)
- [Instance block device mapping \(p. 2031\)](#)

Block device mapping concepts

A *block device* is a storage device that moves data in sequences of bytes or bits (blocks). These devices support random access and generally use buffered I/O. Examples include hard disks, CD-ROM drives, and flash drives. A block device can be physically attached to a computer or accessed remotely as if it were physically attached to the computer.

Amazon EC2 supports two types of block devices:

- Instance store volumes (virtual devices whose underlying hardware is physically attached to the host computer for the instance)
- EBS volumes (remote storage devices)

A *block device mapping* defines the block devices (instance store volumes and EBS volumes) to attach to an instance. You can specify a block device mapping as part of creating an AMI so that the mapping is used by all instances launched from the AMI. Alternatively, you can specify a block device mapping when you launch an instance, so this mapping overrides the one specified in the AMI from which you launched the instance. Note that all NVMe instance store volumes supported by an instance type are automatically enumerated and assigned a device name on instance launch; including them in your block device mapping has no effect.

Contents

- [Block device mapping entries \(p. 2027\)](#)
- [Block device mapping instance store caveats \(p. 2027\)](#)

- [Example block device mapping \(p. 2028\)](#)
- [How devices are made available in the operating system \(p. 2028\)](#)

Block device mapping entries

When you create a block device mapping, you specify the following information for each block device that you need to attach to the instance:

- The device name used within Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume. The name assigned can be different from the name that Amazon EC2 recommends. For more information, see [Device names on Windows instances \(p. 2024\)](#).

For Instance store volumes, you also specify the following information:

- The virtual device: `ephemeral[0-23]`. Note that the number and size of available instance store volumes for your instance varies by instance type.

For NVMe instance store volumes, the following information also applies:

- These volumes are automatically enumerated and assigned a device name; including them in your block device mapping has no effect.

For EBS volumes, you also specify the following information:

- The ID of the snapshot to use to create the block device (`snap-xxxxxxxx`). This value is optional as long as you specify a volume size.
- The size of the volume, in GiB. The specified size must be greater than or equal to the size of the specified snapshot.
- Whether to delete the volume on instance termination (`true` or `false`). The default value is `true` for the root device volume and `false` for attached volumes. When you create an AMI, its block device mapping inherits this setting from the instance. When you launch an instance, it inherits this setting from the AMI.
- The volume type, which can be `gp2` and `gp3` for General Purpose SSD, `io1` and `io2` for Provisioned IOPS SSD, `st1` for Throughput Optimized HDD, `sc1` for Cold HDD, or `standard` for Magnetic. The default value is `gp2`.
- The number of input/output operations per second (IOPS) that the volume supports. (Used only with `io1` and `io2` volumes.)

Block device mapping instance store caveats

There are several caveats to consider when launching instances with AMIs that have instance store volumes in their block device mappings.

- Some instance types include more instance store volumes than others, and some instance types contain no instance store volumes at all. If your instance type supports one instance store volume, and your AMI has mappings for two instance store volumes, then the instance launches with one instance store volume.
- Instance store volumes can only be mapped at launch time. You cannot stop an instance without instance store volumes (such as the `t2.micro`), change the instance to a type that supports instance store volumes, and then restart the instance with instance store volumes. However, you can create an AMI from the instance and launch it on an instance type that supports instance store volumes, and map those instance store volumes to the instance.

- If you launch an instance with instance store volumes mapped, and then stop the instance and change it to an instance type with fewer instance store volumes and restart it, the instance store volume mappings from the initial launch still show up in the instance metadata. However, only the maximum number of supported instance store volumes for that instance type are available to the instance.

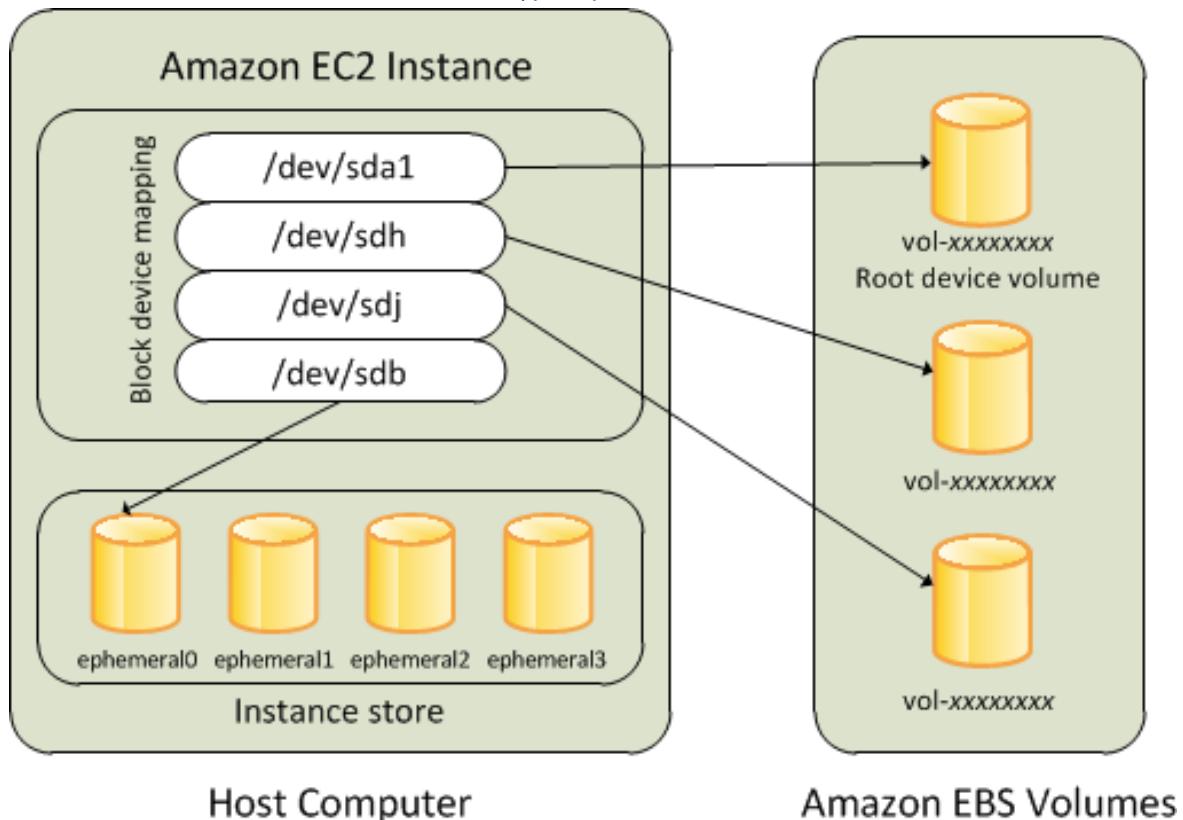

Note

When an instance is stopped, all data on the instance store volumes is lost.

- Depending on instance store capacity at launch time, M3 instances may ignore AMI instance store block device mappings at launch unless they are specified at launch. You should specify instance store block device mappings at launch time, even if the AMI you are launching has the instance store volumes mapped in the AMI, to ensure that the instance store volumes are available when the instance launches.

Example block device mapping

This figure shows an example block device mapping for an EBS-backed instance. It maps /dev/sdb to ephemeral0 and maps two EBS volumes, one to /dev/sdh and the other to /dev/sdj. It also shows the EBS volume that is the root device volume, /dev/sda1.

Note that this example block device mapping is used in the example commands and APIs in this topic. You can find example commands and APIs that create block device mappings in [Specify a block device mapping for an AMI \(p. 2029\)](#) and [Update the block device mapping when launching an instance \(p. 2031\)](#).

How devices are made available in the operating system

Device names like /dev/sdh and xvhd are used by Amazon EC2 to describe block devices. The block device mapping is used by Amazon EC2 to specify the block devices to attach to an EC2 instance. After

a block device is attached to an instance, it must be mounted by the operating system before you can access the storage device. When a block device is detached from an instance, it is unmounted by the operating system and you can no longer access the storage device.

With a Windows instance, the device names specified in the block device mapping are mapped to their corresponding block devices when the instance first boots, and then the Ec2Config service initializes and mounts the drives. The root device volume is mounted as C:\. The instance store volumes are mounted as Z:\, Y:\, and so on. When an EBS volume is mounted, it can be mounted using any available drive letter. However, you can configure how the Ec2Config Service assigns drive letters to EBS volumes; for more information, see [Configure a Windows instance using the EC2Config service \(p. 753\)](#).

AMI block device mapping

Each AMI has a block device mapping that specifies the block devices to attach to an instance when it is launched from the AMI. An AMI that Amazon provides includes a root device only. To add more block devices to an AMI, you must create your own AMI.

Contents

- [Specify a block device mapping for an AMI \(p. 2029\)](#)
- [View the EBS volumes in an AMI block device mapping \(p. 2030\)](#)

Specify a block device mapping for an AMI

There are two ways to specify volumes in addition to the root volume when you create an AMI. If you've already attached volumes to a running instance before you create an AMI from the instance, the block device mapping for the AMI includes those same volumes. For EBS volumes, the existing data is saved to a new snapshot, and it's this new snapshot that's specified in the block device mapping. For instance store volumes, the data is not preserved.

For an EBS-backed AMI, you can add EBS volumes and instance store volumes using a block device mapping. For an instance store-backed AMI, you can add instance store volumes only by modifying the block device mapping entries in the image manifest file when registering the image.

Note

For M3 instances, you must specify instance store volumes in the block device mapping for the instance when you launch it. When you launch an M3 instance, instance store volumes specified in the block device mapping for the AMI may be ignored if they are not specified as part of the instance block device mapping.

To add volumes to an AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **Instances**.
3. Select an instance and choose **Actions, Image and templates, Create image**.
4. Enter a name and a description for the image.
5. The instance volumes appear under **Instance volumes**. To add another volume, choose **Add volume**.
6. For **Volume type**, choose the volume type. For **Device** choose the device name. For an EBS volume, you can specify additional details, such as a snapshot, volume size, volume type, IOPS, and encryption state.
7. Choose **Create image**.

To add volumes to an AMI using the command line

Use the [create-image](#) AWS CLI command to specify a block device mapping for an EBS-backed AMI. Use the [register-image](#) AWS CLI command to specify a block device mapping for an instance store-backed AMI.

Specify the block device mapping using the `--block-device-mappings` parameter. Arguments encoded in JSON can be supplied either directly on the command line or by reference to a file:

```
--block-device-mappings [mapping, ...]  
--block-device-mappings [file://mapping.json]
```

To add an instance store volume, use the following mapping.

```
{  
    "DeviceName": "xvdb",  
    "VirtualName": "ephemeral0"  
}
```

To add an empty 100 GiB gp2 volume, use the following mapping.

```
{  
    "DeviceName": "xvdg",  
    "Ebs": {  
        "VolumeSize": 100  
    }  
}
```

To add an EBS volume based on a snapshot, use the following mapping.

```
{  
    "DeviceName": "xvdh",  
    "Ebs": {  
        "SnapshotId": "snap-xxxxxxxx"  
    }  
}
```

To omit a mapping for a device, use the following mapping.

```
{  
    "DeviceName": "xvdj",  
    "NoDevice": ""  
}
```

Alternatively, you can use the `-BlockDeviceMapping` parameter with the following commands (AWS Tools for Windows PowerShell):

- [New-EC2Image](#)
- [Register-EC2Image](#)

View the EBS volumes in an AMI block device mapping

You can easily enumerate the EBS volumes in the block device mapping for an AMI.

To view the EBS volumes for an AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **AMIs**.

3. Choose **EBS images** from the **Filter** list to get a list of EBS-backed AMIs.
4. Select the desired AMI, and look at the **Details** tab. At a minimum, the following information is available for the root device:
 - **Root Device Type** (ebs)
 - **Root Device Name** (for example, /dev/sda1)
 - **Block Devices** (for example, /dev/sda1=snap-1234567890abcdef0:8:true)

If the AMI was created with additional EBS volumes using a block device mapping, the **Block Devices** field displays the mapping for those additional volumes as well. (This screen doesn't display instance store volumes.)

To view the EBS volumes for an AMI using the command line

Use the [describe-images](#) (AWS CLI) command or [Get-EC2Image](#) (AWS Tools for Windows PowerShell) command to enumerate the EBS volumes in the block device mapping for an AMI.

Instance block device mapping

By default, an instance that you launch includes any storage devices specified in the block device mapping of the AMI from which you launched the instance. You can specify changes to the block device mapping for an instance when you launch it, and these updates overwrite or merge with the block device mapping of the AMI.

Limitations

- For the root volume, you can only modify the following: volume size, volume type, and the **Delete on Termination** flag.
- When you modify an EBS volume, you can't decrease its size. Therefore, you must specify a snapshot whose size is equal to or greater than the size of the snapshot specified in the block device mapping of the AMI.

Contents

- [Update the block device mapping when launching an instance \(p. 2031\)](#)
- [Update the block device mapping of a running instance \(p. 2033\)](#)
- [View the EBS volumes in an instance block device mapping \(p. 2033\)](#)
- [View the instance block device mapping for instance store volumes \(p. 2034\)](#)

Update the block device mapping when launching an instance

You can add EBS volumes and instance store volumes to an instance when you launch it. Note that updating the block device mapping for an instance doesn't make a permanent change to the block device mapping of the AMI from which it was launched.

To add volumes to an instance using the console

1. Open the Amazon EC2 console.
2. From the dashboard, choose **Launch Instance**.
3. On the **Choose an Amazon Machine Image (AMI)** page, select the AMI to use and choose **Select**.
4. Follow the wizard to complete the **Choose an Instance Type** and **Configure Instance Details** pages.
5. On the **Add Storage** page, you can modify the root volume, EBS volumes, and instance store volumes as follows:

- To change the size of the root volume, locate the **Root** volume under the **Type** column, and change its **Size** field.
 - To suppress an EBS volume specified by the block device mapping of the AMI used to launch the instance, locate the volume and click its **Delete** icon.
 - To add an EBS volume, choose **Add New Volume**, choose **EBS** from the **Type** list, and fill in the fields (**Device**, **Snapshot**, and so on).
 - To suppress an instance store volume specified by the block device mapping of the AMI used to launch the instance, locate the volume, and choose its **Delete** icon.
 - To add an instance store volume, choose **Add New Volume**, select **Instance Store** from the **Type** list, and select a device name from **Device**.
6. Complete the remaining wizard pages, and choose **Launch**.

To add volumes to an instance using the AWS CLI

Use the [run-instances](#) AWS CLI command with the `--block-device-mappings` option to specify a block device mapping for an instance at launch.

For example, suppose that an EBS-backed AMI specifies the following block device mapping:

- `xvdb=ephemeral0`
- `xvdh=snap-1234567890abcdef0`
- `xvdj=:100`

To prevent `xvdj` from attaching to an instance launched from this AMI, use the following mapping.

```
{  
    "DeviceName": "xvdj",  
    "NoDevice": ""  
}
```

To increase the size of `xvdh` to 300 GiB, specify the following mapping. Notice that you don't need to specify the snapshot ID for `xvdh`, because specifying the device name is enough to identify the volume.

```
{  
    "DeviceName": "xvdh",  
    "Ebs": {  
        "VolumeSize": 300  
    }  
}
```

To increase the size of the root volume at instance launch, first call [describe-images](#) with the ID of the AMI to verify the device name of the root volume. For example, `"RootDeviceName": "/dev/xvda"`. To override the size of the root volume, specify the device name of the root device used by the AMI and the new volume size.

```
{  
    "DeviceName": "/dev/xvda",  
    "Ebs": {  
        "VolumeSize": 100  
    }  
}
```

To attach an additional instance store volume, `xvdc`, specify the following mapping. If the instance type doesn't support multiple instance store volumes, this mapping has no effect. If the instance supports NVMe instance store volumes, they are automatically enumerated and assigned an NVMe device name.

```
{  
    "DeviceName": "xvdc",  
    "VirtualName": "ephemeral1"  
}
```

To add volumes to an instance using the AWS Tools for Windows PowerShell

Use the `-BlockDeviceMapping` parameter with the [New-EC2Instance](#) command (AWS Tools for Windows PowerShell).

Update the block device mapping of a running instance

You can use the [modify-instance-attribute](#) AWS CLI command to update the block device mapping of a running instance. You do not need to stop the instance before changing this attribute.

```
aws ec2 modify-instance-attribute --instance-id i-1a2b3c4d --block-device-mappings file://mapping.json
```

For example, to preserve the root volume at instance termination, specify the following in `mapping.json`.

```
[  
    {  
        "DeviceName": "/dev/sda1",  
        "Ebs": {  
            "DeleteOnTermination": false  
        }  
    }  
]
```

Alternatively, you can use the `-BlockDeviceMapping` parameter with the [Edit-EC2InstanceAttribute](#) command (AWS Tools for Windows PowerShell).

View the EBS volumes in an instance block device mapping

You can easily enumerate the EBS volumes mapped to an instance.

Note

For instances launched before the release of the 2009-10-31 API, AWS can't display the block device mapping. You must detach and reattach the volumes so that AWS can display the block device mapping.

To view the EBS volumes for an instance using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **Instances**.
3. In the search box, enter **Root device type**, and then choose **EBS**. This displays a list of EBS-backed instances.
4. Select the desired instance and look at the details displayed in the **Storage** tab. At a minimum, the following information is available for the root device:
 - **Root device type** (for example, **EBS**)
 - **Root device name** (for example, `/dev/xvda`)
 - **Block devices** (for example, `/dev/xvda`, `xvdः`, and `xvdः`)

If the instance was launched with additional EBS volumes using a block device mapping, they appear under **Block devices**. Any instance store volumes do not appear on this tab.

5. To display additional information about an EBS volume, choose its volume ID to go to the volume page. For more information, see [View information about an Amazon EBS volume \(p. 1737\)](#).

To view the EBS volumes for an instance using the command line

Use the [describe-instances](#) (AWS CLI) command or [Get-EC2Instance](#) (AWS Tools for Windows PowerShell) command to enumerate the EBS volumes in the block device mapping for an instance.

View the instance block device mapping for instance store volumes

When you view the block device mapping for your instance, you can see only the EBS volumes, not the instance store volumes. The method you use to view the instance store volumes for your instance depends on the volume type.

NVMe instance store volumes

You can use Disk Management or PowerShell to list both EBS and instance store NVMe volumes. For more information, see [the section called "List NVMe volumes" \(p. 2035\)](#).

HDD or SSD instance store volumes

You can use instance metadata to query the HDD or SSD instance store volumes in the block device mapping. NVMe instance store volumes are not included.

The base URI for all requests for instance metadata is `http://169.254.169.254/latest/`. For more information, see [Instance metadata and user data \(p. 862\)](#).

First, connect to your running instance. From the instance, use this query to get its block device mapping.

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/block-device-mapping/
```

The response includes the names of the block devices for the instance. For example, the output for an instance store-backed m1.small instance looks like this.

```
ami
ephemeral0
root
swap
```

The `ami` device is the root device as seen by the instance. The instance store volumes are named `ephemeral[0-23]`. The `swap` device is for the page file. If you've also mapped EBS volumes, they appear as `ebs1`, `ebs2`, and so on.

To get details about an individual block device in the block device mapping, append its name to the previous query, as shown here.

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/block-device-mapping/ephemeral0
```

The instance type determines the number of instance store volumes that are available to the instance. If the number of instance store volumes in a block device mapping exceeds the number of instance store volumes available to an instance, the additional volumes are ignored. To view the instance store volumes for your instance, open Windows Disk Management. To learn how many instance store volumes are supported by each instance type, see [Instance store volumes \(p. 1999\)](#).

Map disks to volumes on your Windows instance

Your Windows instance comes with an EBS volume that serves as the root volume. If your Windows instance uses AWS PV or Citrix PV drivers, you can optionally add up to 25 volumes, making a total of 26 volumes. For more information, see [Instance volume limits \(p. 2019\)](#).

Depending on the instance type of your instance, you'll have from 0 to 24 possible instance store volumes available to the instance. To use any of the instance store volumes that are available to your instance, you must specify them when you create your AMI or launch your instance. You can also add EBS volumes when you create your AMI or launch your instance, or attach them while your instance is running. For more information, see [Make an Amazon EBS volume available for use on Windows \(p. 1731\)](#).

When you add a volume to your instance, you specify the device name that Amazon EC2 uses. For more information, see [Device names on Windows instances \(p. 2024\)](#). AWS Windows Amazon Machine Images (AMIs) contain a set of drivers that are used by Amazon EC2 to map instance store and EBS volumes to Windows disks and drive letters. If you launch an instance from a Windows AMI that uses AWS PV or Citrix PV drivers, you can use the relationships described on this page to map your Windows disks to your instance store and EBS volumes. If your Windows AMI uses Red Hat PV drivers, you can update your instance to use the Citrix drivers. For more information, see [Upgrade PV drivers on Windows instances \(p. 786\)](#).

Contents

- [List NVMe volumes \(p. 2035\)](#)

List NVMe volumes

You can find the disks on your Windows instance using Disk Management or Powershell.

List NVMe disks using Disk Management

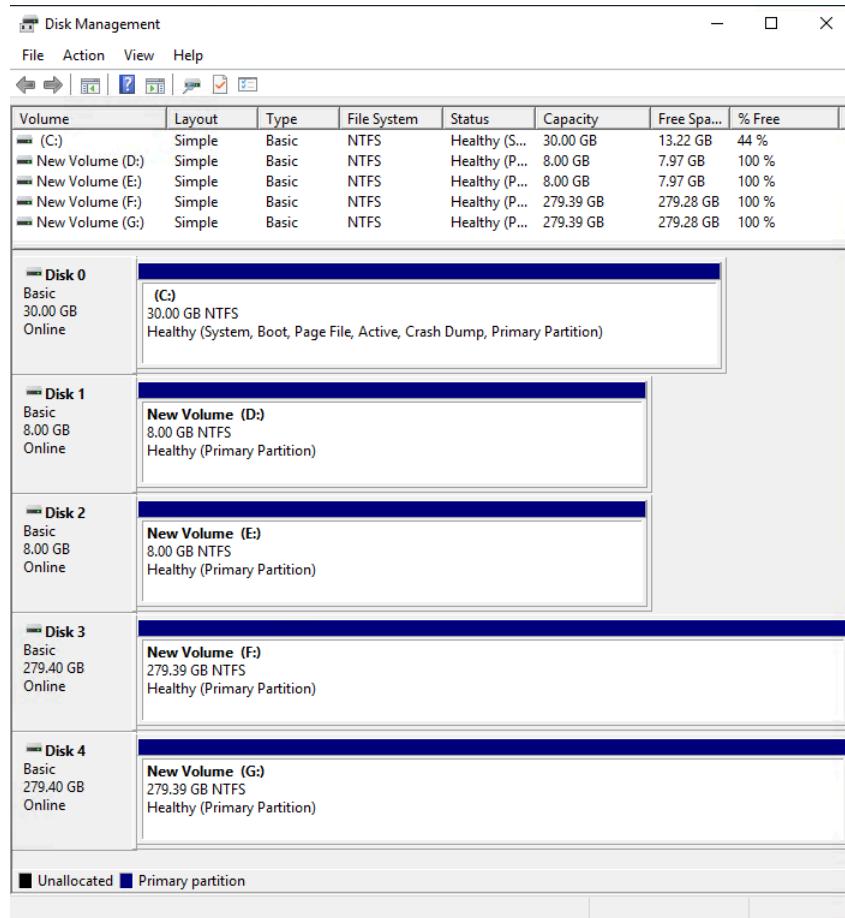

You can find the disks on your Windows instance using Disk Management.

To find the disks on your Windows instance

1. Log in to your Windows instance using Remote Desktop. For more information, see [Connect to your Windows instance \(p. 626\)](#).
2. Start the Disk Management utility.
3. Review the disks. The root volume is an EBS volume mounted as C:\. If there are no other disks shown, then you didn't specify additional volumes when you created the AMI or launched the instance.

The following is an example that shows the disks that are available if you launch an `t5d.4xlarge` instance with two additional EBS volumes.

Amazon Elastic Compute Cloud
User Guide for Windows Instances
List NVMe volumes

List NVMe disks using PowerShell

The following PowerShell script lists each disk and its corresponding device name and volume. It is intended for use with instances build on the [Nitro System \(p. 218\)](#), which use NVMe EBS and instance store volumes.

Connect to your Windows instance and run the following command to enable PowerShell script execution.

```
Set-ExecutionPolicy RemoteSigned
```

Copy the following script and save it as mapping.ps1 on your Windows instance.

```
# List the disks for NVMe volumes

function Get-EC2InstanceMetadata {
    param([string]$Path)
    (Invoke-WebRequest -Uri "http://169.254.169.254/latest/$Path").Content
}

function GetEBSVolumeId {
    param($Path)
    $SerialNumber = (Get-Disk -Path $Path).SerialNumber
    if($SerialNumber -like 'vol*'){

```

```
$EbsVolumeId = $SerialNumber.Substring(0,20).Replace("vol","vol-")
}
else {
    $EbsVolumeId = $SerialNumber.Substring(0,20).Replace("AWS","AWS-")
}
return $EbsVolumeId
}

function GetDeviceName{
    param($EbsVolumeId)
    if($EbsVolumeId -like 'vol*'){

        $Device = ((Get-EC2Volume -VolumeId $EbsVolumeId ).Attachment).Device
        $VolumeName = ""
    }
    else {
        $Device = "Ephemeral"
        $VolumeName = "Temporary Storage"
    }
    Return $Device,$VolumeName
}

function GetDriveLetter{
    param($Path)
    $DiskNumber = (Get-Disk -Path $Path).Number
    if($DiskNumber -eq 0){
        $VirtualDevice = "root"
        $DriveLetter = "C"
        $PartitionNumber = (Get-Partition -DriveLetter C).PartitionNumber
    }
    else
    {
        $VirtualDevice = "N/A"
        $DriveLetter = (Get-Partition -DiskNumber $DiskNumber).DriveLetter
        if(!$DriveLetter)
        {
            $DriveLetter = ((Get-Partition -DiskId $Path).AccessPaths).Split(",")[0]
        }
        $PartitionNumber = (Get-Partition -DiskId $Path).PartitionNumber
    }
    return $DriveLetter,$VirtualDevice,$PartitionNumber
}

$Report = @()
foreach($Path in (Get-Disk).Path)
{
    $Disk_ID = ( Get-Partition -DiskId $Path).DiskId
    $Disk = ( Get-Disk -Path $Path).Number
    $EbsVolumeId = GetEBSVolumeId($Path)
    $Size =(Get-Disk -Path $Path).Size
    $DriveLetter,$VirtualDevice, $Partition = (GetDriveLetter($Path))
    $Device,$VolumeName = GetDeviceName($EbsVolumeId)
    $Disk = New-Object PSObject -Property @{
        Disk          = $Disk
        Partitions   = $Partition
        DriveLetter  = $DriveLetter
        EbsVolumeId  = $EbsVolumeId
        Device       = $Device
        VirtualDevice = $VirtualDevice
        VolumeName   = $VolumeName
    }
    $Report += $Disk
}
```

```
$Report | Sort-Object Disk | Format-Table -AutoSize -Property Disk, Partitions,  
DriveLetter, EbsVolumeId, Device, VirtualDevice, VolumeName
```

Run the script as follows:

```
PS C:\> .\mapping.ps1
```

The following is example output for an instance with a root volume, two EBS volumes, and two instance store volumes.

Disk	Partitions	DriveLetter	EbsVolumeId	Device	VirtualDevice	VolumeName
0	1	C	vol-03683f1d861744bc7	/dev/sda1	root	
1	1	D	vol-082b07051043174b9	xvdb	N/A	
2	1	E	vol-0a4064b39e5f534a2	xvdc	N/A	
3	1	F	AWS-6AAD8C2AEEE1193F0	Ephemeral	N/A	Temporary Storage
4	1	G	AWS-13E7299C2BD031A28	Ephemeral	N/A	Temporary Storage

If you did not provide your credentials on the Windows instance, the script cannot get the EBS volume ID and uses N/A in the EbsVolumeId column.

Map NVMe EBS volumes

With instances built on the [Nitro System \(p. 218\)](#), EBS volumes are exposed as NVMe devices. You can use the [Get-Disk](#) command to map Windows disk numbers to EBS volume IDs. For more information, see [Identify the EBS device \(p. 1940\)](#).

```
PS C:\> Get-Disk  
Number Friendly Name Serial Number HealthStatus  
OperationalStatus Total Size Partition  
  
Style  
-----  
-----  
3 NVMe Amazo... AWS6AAD8C2AEEE1193F0_00000001. Healthy Online  
279.4 GB MBR  
4 NVMe Amazo... AWS13E7299C2BD031A28_00000001. Healthy Online  
279.4 GB MBR  
2 NVMe Amazo... vol0a4064b39e5f534a2_00000001. Healthy Online  
8 GB MBR  
0 NVMe Amazo... vol03683f1d861744bc7_00000001. Healthy Online  
30 GB MBR  
1 NVMe Amazo... vol082b07051043174b9_00000001. Healthy Online  
8 GB MBR
```

You can also run the **ebsnvme-id** command to map NVMe disk numbers to EBS volume IDs and device names.

```
PS C:\> C:\PROGRAMDATA\Amazon\Tools\ebsnvme-id.exe  
Disk Number: 0  
Volume ID: vol-03683f1d861744bc7  
Device Name: sda1  
  
Disk Number: 1  
Volume ID: vol-082b07051043174b9  
Device Name: xvdb  
  
Disk Number: 2  
Volume ID: vol-0a4064b39e5f534a2  
Device Name: xvdc
```

List volumes

You can find the disks on your Windows instance using Disk Management or Powershell.

List disks using Disk Management

You can find the disks on your Windows instance using Disk Management.

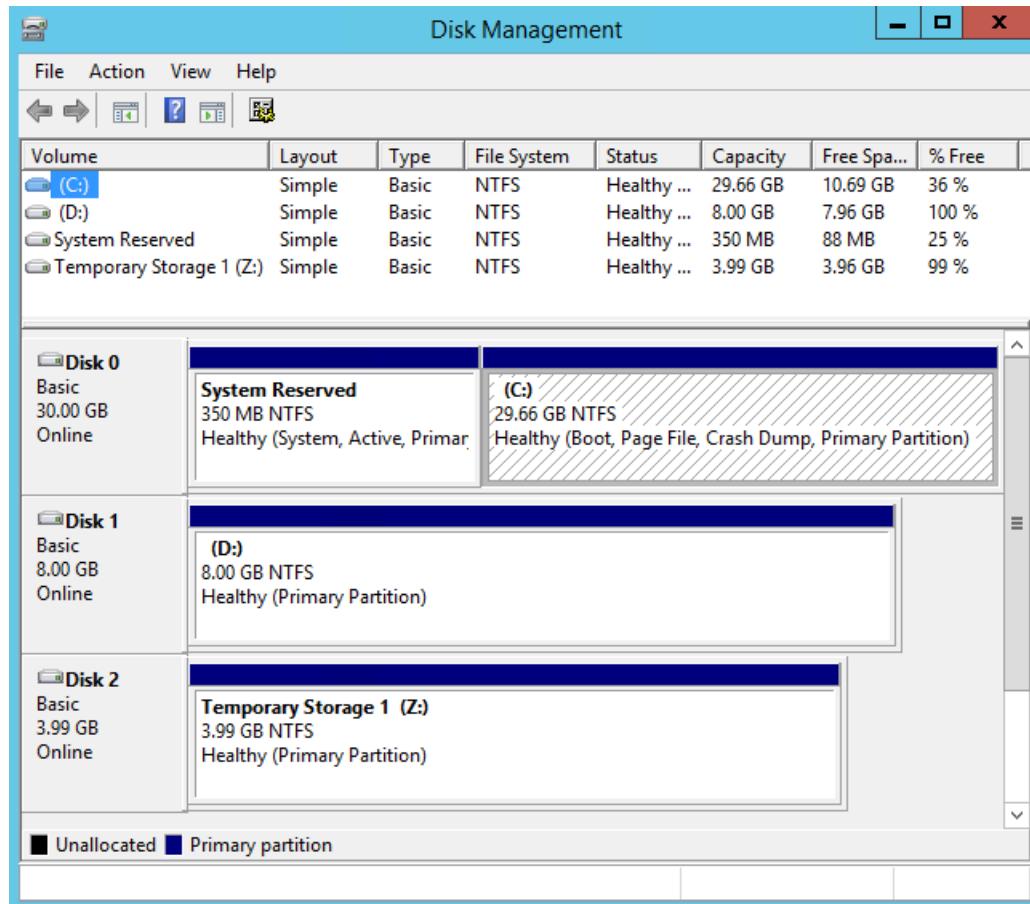

To find the disks on your Windows instance

1. Log in to your Windows instance using Remote Desktop. For more information, see [Connect to your Windows instance \(p. 626\)](#).
2. Start the Disk Management utility.

On Windows Server 2012 and later, on the taskbar, right-click the Windows logo, and then choose **Disk Management**. On Windows Server 2008, choose **Start, Administrative Tools, Computer Management, Disk Management**.

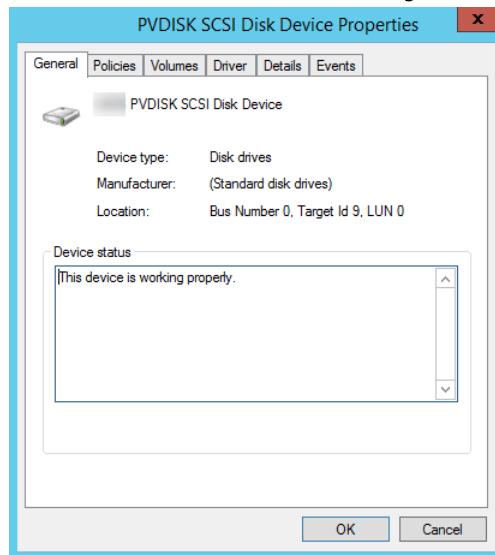

3. Review the disks. The root volume is an EBS volume mounted as C:\. If there are no other disks shown, then you didn't specify additional volumes when you created the AMI or launched the instance.

The following is an example that shows the disks that are available if you launch an m3.medium instance with an instance store volume (Disk 2) and an additional EBS volume (Disk 1).

4. Right-click the gray pane labeled Disk 1, and then select **Properties**. Note the value of **Location** and look it up in the tables in [Map disk devices to device names \(p. 2040\)](#). For example, the following

disk has the location Bus Number 0, Target Id 9, LUN 0. According to the table for EBS volumes, the device name for this location is xvdj.

Map disk devices to device names

The block device driver for the instance assigns the actual volume names when mounting volumes.

Mappings

- [Instance store volumes \(p. 2040\)](#)
- [EBS volumes \(p. 2041\)](#)

Instance store volumes

The following table describes how the Citrix PV and AWS PV drivers map non-NVMe instance store volumes to Windows volumes. The number of available instance store volumes is determined by the instance type. For more information, see [Instance store volumes \(p. 1999\)](#).

Location	Device name
Bus Number 0, Target ID 78, LUN 0	xvdca
Bus Number 0, Target ID 79, LUN 0	xvdcb
Bus Number 0, Target ID 80, LUN 0	xvdcc
Bus Number 0, Target ID 81, LUN 0	xvdcd
Bus Number 0, Target ID 82, LUN 0	xvdce
Bus Number 0, Target ID 83, LUN 0	xvdcf
Bus Number 0, Target ID 84, LUN 0	xvdcg
Bus Number 0, Target ID 85, LUN 0	xvdch
Bus Number 0, Target ID 86, LUN 0	xvdci

Location	Device name
Bus Number 0, Target ID 87, LUN 0	xvdcj
Bus Number 0, Target ID 88, LUN 0	xvdck
Bus Number 0, Target ID 89, LUN 0	xvdcl

EBS volumes

The following table describes how the Citrix PV and AWS PV drivers map non-NVME EBS volumes to Windows volumes.

Location	Device name
Bus Number 0, Target ID 0, LUN 0	/dev/sda1
Bus Number 0, Target ID 1, LUN 0	xvdb
Bus Number 0, Target ID 2, LUN 0	xvdc
Bus Number 0, Target ID 3, LUN 0	xvdd
Bus Number 0, Target ID 4, LUN 0	xvde
Bus Number 0, Target ID 5, LUN 0	xvdf
Bus Number 0, Target ID 6, LUN 0	xvdg
Bus Number 0, Target ID 7, LUN 0	xvdh
Bus Number 0, Target ID 8, LUN 0	xvdi
Bus Number 0, Target ID 9, LUN 0	xvdj
Bus Number 0, Target ID 10, LUN 0	xvdk
Bus Number 0, Target ID 11, LUN 0	xndl
Bus Number 0, Target ID 12, LUN 0	xvdm
Bus Number 0, Target ID 13, LUN 0	xvdn
Bus Number 0, Target ID 14, LUN 0	xvdo
Bus Number 0, Target ID 15, LUN 0	xvdp
Bus Number 0, Target ID 16, LUN 0	xvdq
Bus Number 0, Target ID 17, LUN 0	xvdr
Bus Number 0, Target ID 18, LUN 0	xvds
Bus Number 0, Target ID 19, LUN 0	xvdt
Bus Number 0, Target ID 20, LUN 0	xvdu
Bus Number 0, Target ID 21, LUN 0	xvdv
Bus Number 0, Target ID 22, LUN 0	xvdw

Location	Device name
Bus Number 0, Target ID 23, LUN 0	xvdx
Bus Number 0, Target ID 24, LUN 0	xvdy
Bus Number 0, Target ID 25, LUN 0	xvdz

List disks using PowerShell

The following PowerShell script lists each disk and its corresponding device name and volume.

Requirements and limitations

- Requires Windows Server 2012 or later.
- Requires credentials to get the EBS volume ID. You can configure a profile using the Tools for PowerShell, or attach an IAM role to the instance.
- Does not support NVMe volumes.
- Does not support dynamic disks.

Connect to your Windows instance and run the following command to enable PowerShell script execution.

```
Set-ExecutionPolicy RemoteSigned
```

Copy the following script and save it as mapping.ps1 on your Windows instance.

```
# List the disks
function Convert-SCSITargetIdToDeviceName {
    param([int]$SCSITargetId)
    If ($SCSITargetId -eq 0) {
        return "sda1"
    }
    $deviceName = "xvd"
    If ($SCSITargetId -gt 25) {
        $deviceName += [char](0x60 + [int]($SCSITargetId / 26))
    }
    $deviceName += [char](0x61 + $SCSITargetId % 26)
    return $deviceName
}

```

Run the script as follows:

```
PS C:\> .\mapping.ps1
```

The following is example output.

Disk	Partitions	DriveLetter	EbsVolumeId	Device	VirtualDevice
DeviceName			VolumeName		
0	1	C	vol-0561f1783298efedd	/dev/sda1	N/A
Amazon Elastic B	N/A				NVMe
1	1	D	vol-002a9488504c5e35a	xvdb	N/A
Amazon Elastic B	N/A				NVMe
2	1	E	vol-0de9d46fcc907925d	xvdc	N/A
Amazon Elastic B	N/A				NVMe

If you did not provide your credentials on the Windows instance, the script cannot get the EBS volume ID and uses N/A in the EbsVolumeId column.

Resources and tags

Amazon EC2 provides different *resources* that you can create and use. Some of these resources include images, instances, volumes, and snapshots. When you create a resource, we assign the resource a unique resource ID.

Some resources can be tagged with values that you define, to help you organize and identify them.

The following topics describe resources and tags, and how you can work with them.

Contents

- [Recycle Bin \(p. 2045\)](#)
- [Resource locations \(p. 2075\)](#)
- [Resource IDs \(p. 2076\)](#)
- [List and filter your resources \(p. 2077\)](#)
- [Tag your Amazon EC2 resources \(p. 2085\)](#)
- [Amazon EC2 service quotas \(p. 2100\)](#)
- [Amazon EC2 usage reports \(p. 2102\)](#)

Recycle Bin

Recycle Bin is a data recovery feature that enables you to restore accidentally deleted Amazon EBS snapshots and EBS-backed AMIs. When using Recycle Bin, if your resources are deleted, they are retained in the Recycle Bin for a time period that you specify before being permanently deleted.

You can restore a resource from the Recycle Bin at any time before its retention period expires. After you restore a resource from the Recycle Bin, the resource is removed from the Recycle Bin and you can use it in the same way that you use any other resource of that type in your account. If the retention period expires and the resource is not restored, the resource is permanently deleted from the Recycle Bin and it is no longer available for recovery.

Using Recycle Bin helps to ensure business continuity by protecting your business-critical data against accidental deletion.

Topics

- [How does it work? \(p. 2045\)](#)
- [Supported resources \(p. 2046\)](#)
- [Considerations \(p. 2046\)](#)
- [Quotas \(p. 2048\)](#)
- [Related services \(p. 2049\)](#)
- [Pricing \(p. 2049\)](#)
- [Required IAM permissions \(p. 2049\)](#)
- [Work with retention rules \(p. 2053\)](#)
- [Work with resources in the Recycle Bin \(p. 2062\)](#)
- [Monitor Recycle Bin \(p. 2063\)](#)

How does it work?

To enable and use Recycle Bin, you must create *retention rules* in the AWS Regions in which you want to protect your resources. Retention rules specify the following:

- The resource type that you want to protect.
- The resources that you want to retain in the Recycle Bin when they are deleted.
- The retention period for which to retain resources in the Recycle Bin before they are permanently deleted.

With Recycle Bin, you can create two types of retention rules:

- **Tag-level retention rules** — A tag-level retention rule uses resource tags to identify the resources that are to be retained in the Recycle Bin. For each retention rule, you specify one or more tag key and value pairs. Resources of the specified type that are tagged with at least one of the tag key and value pairs that are specified in the retention rule are automatically retained in the Recycle Bin upon deletion. Use this type of retention rule if you want to protect specific resources in your account based on their tags.
- **Region-level retention rules** — A Region-level retention rule does not have any resource tags specified. It applies to all of the resources of the specified type in the Region in which the rule is created, even if the resources are not tagged. Use this type of retention rule if you want to protect all resources of a specific type in a specific Region.

While a resource is in the Recycle Bin, you have the ability to restore it for use at any time.

The resource remains in the Recycle Bin until one of the following happens:

- You manually restore it for use. When you restore a resource from the Recycle Bin, the resource is removed from the Recycle Bin and it immediately becomes available for use. You can use restored resources in the same way as any other resource of that type in your account.
- The retention period expires. If the retention period expires, and the resource has not been restored from the Recycle Bin, the resource is permanently deleted from the Recycle Bin and it can no longer be viewed or restored.

Supported resources

Recycle Bin supports the following resource types:

- Amazon EBS snapshots
 - Important**
Recycle Bin retention rules also apply to archived snapshots in the archive storage tier. If you delete an archived snapshot that matches a retention rule, that snapshot is retained in the Recycle Bin for the period defined in the retention rule. Archived snapshots are billed at the rate for archived snapshots while they are in the Recycle Bin.
- Amazon EBS-backed Amazon Machine Images (AMIs)

Considerations

The following considerations apply when working with Recycle Bin and retention rules.

General considerations

- **Important**
When you create your first retention rule, it can take up to 30 minutes for the rule to become active and for it to start retaining resources. After you create the first retention rule, subsequent retention rules become active and start retaining resources almost immediately.

- If a resource matches more than one retention rule upon deletion, then the retention rule with the longest retention period takes precedence.
- You can't manually delete a resource from the Recycle Bin. The resource will be automatically deleted when its retention period expires.
- While a resource is in the Recycle Bin, you can only view it, restore it, or modify its tags. To use the resource in any other way, you must first restore it.
- If any AWS service, such as AWS Backup or Amazon Data Lifecycle Manager, deletes a resource that matches a retention rule, that resource is automatically retained by Recycle Bin.
- When a resource is sent to the Recycle Bin, the following system-generate tag is assigned to the resource:
 - Tag key — `aws:recycle-bin:resource-in-bin`
 - Tag value — `true`

You can't manually edit or delete this tag. When the resource is restored from the Recycle Bin, the tag is automatically removed.

Considerations for snapshots

- **Important**
If you have retention rules for AMIs and for their associated snapshots, make the retention period for the snapshots the same or longer than the retention period for the AMIs. This ensures that Recycle Bin does not delete the snapshots associated with an AMI before deleting the AMI itself, as this would make the AMI unrecoverable.
- If a snapshot is enabled for fast snapshot restore when it is deleted, fast snapshot restore is automatically disabled shortly after the snapshot is sent to the Recycle Bin.
 - If you restore the snapshot before fast snapshot restore is disabled for the snapshot, it remains enabled.
 - If you restore the snapshot, after fast snapshot restore has been disabled, it remains disabled. If needed, you must manually re-enable fast snapshot restore.
- If a snapshot is shared when it is deleted, it is automatically unshared when it is sent to the Recycle Bin. If you restore the snapshot, all of the previous sharing permissions are automatically restored.
- If a snapshot that was created by another AWS service, such as AWS Backup is sent to the Recycle Bin and you later restore that snapshot from the Recycle Bin, it is no longer managed by the AWS service that created it. You must manually delete the snapshot if it is no longer needed.

Considerations for AMIs

- Only Amazon EBS-backed AMIs are supported.
- **Important**
If you have retention rules for AMIs and for their associated snapshots, make the retention period for the snapshots the same or longer than the retention period for the AMIs. This ensures that Recycle Bin does not delete the snapshots associated with an AMI before deleting the AMI itself, as this would make the AMI unrecoverable.
- If an AMI is shared when it is deleted, it is automatically unshared when it is sent to the Recycle Bin. If you restore the AMI, all of the previous sharing permissions are automatically restored.
- Before you can restore an AMI from the Recycle Bin, you must first restore all of its associated snapshots from the Recycle Bin and ensure that they are in the available state.
- If the snapshots that are associated with the AMI are deleted from the Recycle Bin, the AMI is no longer recoverable. The AMI will be deleted when the retention period expires.
- If an AMI that was created by another AWS service, such as AWS Backup, is sent to the Recycle Bin and you later restore that AMI from the Recycle Bin, it is no longer managed by the AWS service that created it. You must manually delete the AMI if it is no longer needed.

Considerations for Amazon Data Lifecycle Manager snapshot policies

- If Amazon Data Lifecycle Manager deletes a snapshot that matches a retention rule, that snapshot is automatically retained by Recycle Bin.
- If Amazon Data Lifecycle Manager deletes a snapshot and sends it to the Recycle Bin when the policy's retention threshold is reached, and you manually restore the snapshot from the Recycle Bin, you must manually delete that snapshot when it is no longer needed. Amazon Data Lifecycle Manager will no longer manage the snapshot.
- If you manually delete a snapshot that was created by a policy, and that snapshot is in the Recycle Bin when the policy's retention threshold is reached, Amazon Data Lifecycle Manager will not delete the snapshot. Amazon Data Lifecycle Manager does not manage the snapshots while they are stored in the Recycle Bin.

If the snapshot is restored from the Recycle Bin before the policy's retention threshold is reached, Amazon Data Lifecycle Manager will delete the snapshot when the policy's retention threshold is reached.

If the snapshot is restored from the Recycle Bin after the policy's retention threshold is reached, Amazon Data Lifecycle Manager will no longer delete the snapshot. You must manually delete the snapshot when it is no longer needed.

Considerations for AWS Backup

- If AWS Backup deletes a snapshot that matches a retention rule, that snapshot is automatically retained by Recycle Bin.

Considerations for archived snapshots

- Recycle Bin retention rules also apply to archived snapshots in the archive storage tier. If you delete an archived snapshot that matches a retention rule, that snapshot is retained in the Recycle Bin for the period defined in the retention rule.

Archived snapshots are billed at the rate for archived snapshots while they are in the Recycle Bin.

If a retention rule deletes an archived snapshot from the Recycle Bin before the minimum archive period of 90 days, you are billed for the remaining days. For more information, see [Pricing and billing \(p. 1787\)](#).

To use an archived snapshot that is in the Recycle Bin, you must first recover the snapshot from the Recycle Bin and then restore it from the archive tier to the standard tier.

Quotas

The following quotas apply to Recycle Bin.

Quota	Default quota			
Retention rules per Region	250			
Tag key and value pairs per retention rule	50			

Related services

Recycle Bin works with the following services:

- **AWS CloudTrail** — Enables you to record events that occur in Recycle Bin. For more information, see [Monitor Recycle Bin using AWS CloudTrail \(p. 2065\)](#).

Pricing

Resources in the Recycle Bin are billed at their standard rates. There are no additional charges for using Recycle Bin and retention rules. For more information, see [Amazon EBS pricing](#).

Note

Some resources might still appear in the Recycle Bin console or in the AWS CLI and API output for a short period after their retention periods have expired and they have been permanently deleted. You are not billed for these resources. Billing stops as soon as the retention period expires.

You can use the following AWS generated cost allocation tags for cost tracking and allocation purposes when using AWS Billing and Cost Management.

- Key: `aws:recycle-bin:resource-in-bin`
- Value: `true`

For more information, see [AWS-generated cost allocation tags](#) in the *AWS Billing and Cost Management User Guide*.

Required IAM permissions

By default, users don't have permission to work with Recycle Bin, retention rules, or with resources that are in the Recycle Bin. To allow users to work with these resources, you must create IAM policies that grant permission to use specific resources and API actions. Once the policies are created, you must add permissions to your users, groups, or roles.

Topics

- [Permissions for working with Recycle Bin and retention rules \(p. 2049\)](#)
- [Permissions for working with resources in the Recycle Bin \(p. 2050\)](#)
- [Condition keys for Recycle Bin \(p. 2051\)](#)

Permissions for working with Recycle Bin and retention rules

To work with Recycle Bin and retention rules, users need the following permissions.

- `rbin:CreateRule`
- `rbin:UpdateRule`
- `rbin:GetRule`
- `rbin>ListRules`
- `rbin>DeleteRule`
- `rbin:TagResource`
- `rbin:UntagResource`

- `rbin>ListTagsForResource`
- `rbin>LockRule`
- `rbin>UnlockRule`

To use the Recycle Bin console, users need the `tag:GetResources` permission.

The following is an example IAM policy that includes the `tag:GetResources` permission for console users. If some permissions are not needed, you can remove them from the policy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [{  
        "Effect": "Allow",  
        "Action": [  
            "rbin>CreateRule",  
            "rbin>UpdateRule",  
            "rbin>GetRule",  
            "rbin>ListRules",  
            "rbin>DeleteRule",  
            "rbin>TagResource",  
            "rbin>UntagResource",  
            "rbin>ListTagsForResource",  
            "rbin>LockRule",  
            "rbin>UnlockRule",  
            "tag:GetResources"  
        ],  
        "Resource": "*"  
    }]  
}
```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center (successor to AWS Single Sign-On):

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:

- Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the *IAM User Guide*.
- (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

Permissions for working with resources in the Recycle Bin

For more information about the IAM permissions needed to work with resources in the Recycle Bin, see the following:

- [Permissions for working with snapshots in the Recycle Bin \(p. 1814\)](#)
- [Permissions for working with AMIs in the Recycle Bin \(p. 190\)](#)

Condition keys for Recycle Bin

Recycle Bin defines the following condition keys that you can use in the Condition element of an IAM policy to control the conditions under which the policy statement applies. For more information, see [IAM JSON policy elements: Condition](#) in the *IAM User Guide*.

Topics

- [rbin:Request/ResourceType condition key \(p. 2051\)](#)
- [rbin:Attribute/ResourceType condition key \(p. 2052\)](#)

rbin:Request/ResourceType condition key

The rbin:Request/ResourceType condition key can be used to filter access on [CreateRule](#) and [ListRules](#) requests based on the value specified for the ResourceType request parameter.

Example 1 - CreateRule

The following sample IAM policy allows IAM principals to make **CreateRule** requests only if the value specified for the ResourceType request parameter is EBS_SNAPSHOT or EC2_IMAGE. This allows the principal to create new retention rules for snapshots and AMIs only.

```
{  
    "Version" : "2012-10-17",  
    "Statement" : [  
        {  
            "Effect" : "Allow",  
            "Action" : [  
                "rbin:CreateRule"  
            ],  
            "Resource" : "*",  
            "Condition" : {  
                "StringEquals" : {  
                    "rbin:Request/ResourceType" : ["EBS_SNAPSHOT", "EC2_IMAGE"]  
                }  
            }  
        }  
    ]  
}
```

Example 2 - ListRules

The following sample IAM policy allows IAM principals to make **ListRules** requests only if the value specified for the ResourceType request parameter is EBS_SNAPSHOT. This allows the principal to list retention rules for snapshots only, and it prevents them from listing retention rules for any other resource type.

```
{  
    "Version" : "2012-10-17",  
    "Statement" : [  
        {  
            "Effect" : "Allow",  
            "Action" : [  
                "rbin>ListRules"  
            ],  
            "Resource" : "*",  
            "Condition" : {  
                "StringEquals" : {  
                    "rbin:Request/ResourceType" : "EBS_SNAPSHOT"  
                }  
            }  
        }  
    ]  
}
```

```
        }
    ]
}
```

rbin:Attribute/ResourceType condition key

The `rbin:Attribute/ResourceType` condition key can be used to filter access on [DeleteRule](#), [GetRule](#), [UpdateRule](#), [LockRule](#), [UnlockRule](#), [TagResource](#), [UntagResource](#), and [ListTagsForResource](#) requests based on the value of the retention rule's `ResourceType` attribute.

Example 1 - UpdateRule

The following sample IAM policy allows IAM principals to make **UpdateRule** requests only if the `ResourceType` attribute of the requested retention rule is `EBS_SNAPSHOT` or `EC2_IMAGE`. This allows the principal to update retention rules for snapshots and AMIs only.

```
{
    "Version" : "2012-10-17",
    "Statement" : [
        {
            "Effect" : "Allow",
            "Action" :[
                "rbin:UpdateRule"
            ],
            "Resource" : "*",
            "Condition" : {
                "StringEquals" : {
                    "rbin:Attribute/ResourceType" : ["EBS_SNAPSHOT", "EC2_IMAGE"]
                }
            }
        }
    ]
}
```

Example 2 - DeleteRule

The following sample IAM policy allows IAM principals to make **DeleteRule** requests only if the `ResourceType` attribute of the requested retention rule is `EBS_SNAPSHOT`. This allows the principal to delete retention rules for snapshots only.

```
{
    "Version" : "2012-10-17",
    "Statement" : [
        {
            "Effect" : "Allow",
            "Action" :[
                "rbin:DeleteRule"
            ],
            "Resource" : "*",
            "Condition" : {
                "StringEquals" : {
                    "rbin:Attribute/ResourceType" : "EBS_SNAPSHOT"
                }
            }
        }
    ]
}
```

Work with retention rules

To enable and use Recycle Bin, you must create *retention rules* in the AWS Regions in which you want to protect your resources. Retention rules specify the following:

- The resource type that you want to protect.
- The resources that you want to retain in the Recycle Bin when they are deleted.
- The retention period for which to retain resources in the Recycle Bin before they are permanently deleted.

With Recycle Bin, you can create two types of retention rules:

- **Tag-level retention rules** — A tag-level retention rule uses resource tags to identify the resources that are to be retained in the Recycle Bin. For each retention rule, you specify one or more tag key and value pairs. Resources of the specified type that are tagged with at least one of the tag key and value pairs that are specified in the retention rule are automatically retained in the Recycle Bin upon deletion. Use this type of retention rule if you want to protect specific resources in your account based on their tags.
- **Region-level retention rules** — A Region-level retention rule does not have any resource tags specified. It applies to all of the resources of the specified type in the Region in which the rule is created, even if the resources are not tagged. Use this type of retention rule if you want to protect all resources of a specific type in a specific Region.

After you create a retention rule, resources that match its criteria are automatically retained in the Recycle Bin for the specified retention period after they are deleted.

Topics

- [Create a retention rule \(p. 2053\)](#)
- [View Recycle Bin retention rules \(p. 2056\)](#)
- [Update retention rules \(p. 2056\)](#)
- [Lock retention rules \(p. 2057\)](#)
- [Unlock retention rules \(p. 2059\)](#)
- [Tag retention rules \(p. 2060\)](#)
- [View retention rule tags \(p. 2060\)](#)
- [Remove tags from retention rules \(p. 2061\)](#)
- [Delete Recycle Bin retention rules \(p. 2061\)](#)

Create a retention rule

When you create a retention rule, you must specify the following required parameters:

- The resource type that is to be protected by the retention rule.
- The resources that are to be protected by the retention rule. You can create retention rules at the tag level and the Region level.
 - To create a tag-level retention rule, specify the resource tags that identify the resources to protect. You can specify up to 50 tags for each rule, and add the same tag key and value pair to a maximum of five retention rules.
 - To create a Region-level retention rule, do not specify any tag key and value pairs. In this case, all resources of the specified type are protected.
- The period to retain the resources in the Recycle Bin after they are deleted. The period can be up to 1 year (365 days).

You can also specify the following optional parameters:

- An optional name for the retention rule. The name can be up to 255 characters long.
- An optional description for the retention rule. The description can be up to 255 characters long.

Note

We recommend that you do not include personally identifying, confidential, or sensitive information in the retention rule description.

- Optional retention rule tags to help identify and organize your retention rules. You can assign up to 50 tags to each rule.

You can also optionally lock retention rules on creation. If you lock a retention rule on creation, you must also specify the unlock delay period, which can be 7 to 30 days. Retention rules remain unlocked by default unless you explicitly lock them.

Retention rules function only in the Regions in which they are created. If you intend to use Recycle Bin in other Regions, you must create additional retention rules in those Regions.

You can create a Recycle Bin retention rule using one of the following methods.

Recycle Bin console

To create a retention rule

1. Open the Recycle Bin console at <https://console.aws.amazon.com/rbin/home/>
2. In the navigation pane, choose **Retention rules**, and then choose **Create retention rule**.
3. In the **Rule details** section, do the following:
 - a. (*Optional*) For **Retention rule name**, enter a descriptive name for the retention rule.
 - b. (*Optional*) For **Retention rule description**, enter a brief description for the retention rule.
4. In the **Rule settings** section, do the following:
 - a. For **Resource type**, select choose the type of resource for the retention rule to protect. The retention rule will retain only resources of this type in the Recycle Bin.
 - b. Do one of the following:
 - To create a Region-level retention rule that matches all deleted resources of the specified type in the Region, select **Apply to all resources**. The retention rule will retain all deleted resources of the specified type in the Recycle Bin upon deletion, even if the resources do not have any tags.
 - To create a tag-level retention rule, for **Resource tags to match**, enter the tag key and value pairs to use to identify resource of the specified type that are to be retained in the Recycle Bin. Only resources of the specified type that have at least one of the specified tag key and value pairs will be retained by the retention rule.
 - c. For **Retention period**, enter the number of days for which the retention rule is to retain resources in the Recycle Bin.
5. (*Optional*) To lock the retention rule, for **Rule lock settings**, select **Lock**, and then for **Unlock delay period**, specify the unlock delay period in days. A locked retention rule can't be modified or deleted. To modify or delete the rule, you must first unlock it and then wait for the unlock delay period to expire. For more information, see [Lock retention rules \(p. 2057\)](#)

To leave the retention rule unlocked, for **Rule lock settings**, keep **Unlock** selected. An unlocked retention rule can be modified or deleted at any time. For more information, see [Unlock retention rules \(p. 2059\)](#).

6. (*Optional*) In the **Tags** section, do the following:

- To tag the rule with custom tags, choose **Add tag** and then enter the tag key and value pair.
7. Choose **Create retention rule**.

AWS CLI

To create a retention rule

Use the [create-rule](#) AWS CLI command. For `--retention-period`, specify the number of days to retain deleted snapshots in the Recycle Bin. For `--resource-type`, specify `EBS_SNAPSHOT` for snapshots or `EC2_IMAGE` for AMIs. To create a tag-level retention rule, for `--resource-tags`, specify the tags to use to identify the snapshots that are to be retained. To create a Region-level retention rule, omit `--resource-tags`. To lock a retention rule, include `--lock-configuration`, and specify the unlock delay period in days.

```
C:\> aws rbin create-rule \
--retention-period RetentionPeriodValue=number_of_days,RetentionPeriodUnit= DAYS \
--resource-type EBS_SNAPSHOT/EC2_IMAGE \
--description "rule_description" \
--lock-configuration
'UnlockDelay={UnlockDelayUnit= DAYS,UnlockDelayValue=unlock_delay_in_days}' \
--resource-tags ResourceTagKey=tag_key,ResourceTagValue=tag_value
```

Example 1

The following example command creates an unlocked Region-level retention rule that retains all deleted snapshots for a period of 7 days.

```
C:\> aws rbin create-rule \
--retention-period RetentionPeriodValue=7,RetentionPeriodUnit= DAYS \
--resource-type EBS_SNAPSHOT \
--description "Match all snapshots"
```

Example 2

The following example command creates a tag-level rule that retains deleted snapshots that are tagged with `purpose=production` for a period of 7 days.

```
C:\> aws rbin create-rule \
--retention-period RetentionPeriodValue=7,RetentionPeriodUnit= DAYS \
--resource-type EBS_SNAPSHOT \
--description "Match snapshots with a specific tag" \
--resource-tags ResourceTagKey=purpose,ResourceTagValue=production
```

Example 3

The following example command creates a locked Region-level retention rule that retains all deleted snapshots for a period of 7 days. The retention rule is locked with an unlock delay period of 7 days.

```
C:\> aws rbin create-rule \
--retention-period RetentionPeriodValue=7,RetentionPeriodUnit= DAYS \
--resource-type EBS_SNAPSHOT \
--description "Match all snapshots" \
--lock-configuration 'UnlockDelay={UnlockDelayUnit= DAYS,UnlockDelayValue=7}'
```

View Recycle Bin retention rules

You can view Recycle Bin retention rules using one of the following methods.

Recycle Bin console

To view retention rules

1. Open the Recycle Bin console at <https://console.aws.amazon.com/rbin/home/>
2. In the navigation pane, choose **Retention rules**.
3. The grid lists all of the retention rules for the selected Region. To view more information about a specific retention rule, select it in the grid.

AWS CLI

To view all of your retention rules

Use the [list-rules](#) AWS CLI command, and for --resource-type, specify EBS_SNAPSHOT for snapshots or EC2_IMAGE for AMIs.

```
C:\> aws rbin list-rules --resource-type EBS_SNAPSHOT|EC2_IMAGE
```

Example

The following example command provides lists all retention rules that retain snapshots.

```
C:\> aws rbin list-rules --resource-type EBS_SNAPSHOT
```

To view information for a specific retention rule

Use the [get-rule](#) AWS CLI command.

```
C:\> aws rbin get-rule --identifier rule_ID
```

Example

The following example command provides information about retention rule pwxIkFcvge4.

```
C:\> aws rbin get-rule --identifier pwxIkFcvge4
```

Update retention rules

You can update an unlocked retention rule's description, resource tags, and retention period at any time after creation. You can't update a retention rule's resource type or unlock delay period, even if the retention rule is unlocked.

You can't update a locked retention rule in any way. If you need to modify a locked retention rule, you must first unlock it and wait for the unlock delay period to expire.

If you need to modify the unlock delay period for a locked retention rule, you must [unlock the retention rule \(p. 2059\)](#), and wait for the current unlock delay period to expire. When the unlock delay period is expired, you must [relock the retention rule \(p. 2057\)](#) and specify the new unlock delay period.

Note

We recommend that you do not include personally identifying, confidential, or sensitive information in the retention rule description.

After you update a retention rule, the changes only apply to new resources that it retains. The changes do not affect resources that it previously sent to the Recycle Bin. For example, if you update a retention rule's retention period, only snapshots that are deleted after the update are retained for the new retention period. Snapshots that it sent to the Recycle Bin before the update are still retained for the previous (old) retention period.

You can update a retention rule using one of the following methods.

Recycle Bin console

To update a retention rule

1. Open the Recycle Bin console at <https://console.aws.amazon.com/rbin/home/>
2. In the navigation pane, choose **Retention rules**.
3. In the grid, select the retention rule to update, and choose **Actions**, **Edit retention rule**.
4. In the **Rule details** section, update **Retention rule name** and **Retention rule description** as needed.
5. In the **Rule settings** section, update the **Resource type**, **Resource tags to match**, and **Retention period** as needed.
6. In the **Tags** section, add or remove retention rule tags as needed.
7. Choose **Save retention rule**.

AWS CLI

To update a retention rule

Use the `update-rule` AWS CLI command. For `--identifier`, specify the ID of the retention rule to update. For `--resource-types`, specify `EBS_SNAPSHOT` for snapshots or `EC2_IMAGE` for AMIs.

```
C:\> aws rbin update-rule \
--identifier rule_ID \
--retention-period RetentionPeriodValue=number_of_days,RetentionPeriodUnit=DAYs \
--resource-type EBS_SNAPSHOT|EC2_IMAGE \
--description "rule_description"
```

Example

The following example command updates retention rule `6lsJ2Fa9nh9` to retain all snapshots for 7 days and updates its description.

```
C:\> aws rbin update-rule \
--identifier 6lsJ2Fa9nh9 \
--retention-period RetentionPeriodValue=7,RetentionPeriodUnit=DAYs \
--resource-type EBS_SNAPSHOT \
--description "Retain for three weeks"
```

Lock retention rules

Recycle Bin lets you lock Region-level retention rules at any time.

Note

You can't lock tag-level retention rules.

A locked retention rule can't be modified or deleted, even by users who have the required IAM permissions. Lock your retention rules to help protect them against accidental or malicious modifications and deletions.

When you lock a retention rule, you must specify an unlock delay period. This is the period of time that you must wait after unlocking the retention rule before you can modify or delete it. You cannot modify or delete the retention rule during the unlock delay period. You can modify or delete the retention rule only after the unlock delay period has expired.

You can't change the unlock delay period after the retention rule has been locked. If your account permissions have been compromised, the unlock delay period gives you additional time to detect and respond to security threats. The length of this period should be longer than the time it takes for you to identify and respond to security breaches. To set the right duration, you can review previous security incidents and the time needed to identify and remediate an account breach.

We recommend that you use Amazon EventBridge rules to notify you of retention rule lock state changes. For more information, see [Monitor Recycle Bin using Amazon EventBridge \(p. 2063\)](#).

Considerations

- You can lock Region-level retention rules only.
- You can lock an unlocked retention rule at any time.
- The unlock delay period must be 7 to 30 days.
- You can re-lock a retention rule during the unlock delay period. Relocking the retention rule resets the unlock delay period.

You can lock a Region-level retention rule using one of the following methods.

Recycle Bin console

To lock a retention rule

1. Open the Recycle Bin console at <https://console.aws.amazon.com/rbin/home/>
2. In the navigation panel, choose **Retention rules**.
3. In the grid, select the unlocked retention rule to lock, and choose **Actions**, **Edit retention rule lock**.
4. In the Edit retention rule lock screen, choose **Lock**, and then for **Unlock delay period**, specify the unlock delay period in days.
5. Select the **I acknowledge that locking the retention rule will prevent it from being modified or deleted** check box, and then choose **Save**.

AWS CLI

To lock an unlocked retention rule

Use the [lock-rule](#) AWS CLI command. For **--identifier**, specify the ID of the retention rule to lock. For **--lock-configuration**, specify the unlock delay period in days.

```
C:\> aws rbin lock-rule \
--identifier rule_ID \
--lock-configuration
'UnlockDelay={UnlockDelayUnit=DAY,UnlockDelayValue=number_of_days}'
```

Example

The following example command locks retention rule 61sJ2Fa9nh9 and sets the unlock delay period to 15 days.

```
C:\> aws rbin lock-rule \
```

```
--identifier 6lsJ2Fa9nh9 \
--lock-configuration 'UnlockDelay={UnlockDelayUnit=DAYs,UnlockDelayValue=15}'
```

Unlock retention rules

You can't modify or delete a locked retention rule. If you need to modify a locked retention rule, you must first unlock it. After you have unlocked the retention rule, you must wait for the unlock delay period to expire before you modify or delete it. You can't modify or delete a retention rule during the unlock delay period.

An unlocked retention rule can be modified and deleted at any time by a user who has the required IAM permissions. Leaving your retention rules unlocked could expose them to accidental or malicious modifications and deletions.

Considerations

- You can re-lock a retention rule during the unlock delay period.
- You can re-lock a retention rule after the unlock delay period has expired.
- You can't bypass the unlock delay period.
- You can't change the unlock delay period after the initial lock.

We recommend that you use Amazon EventBridge rules to notify you of retention rule lock state changes. For more information, see [Monitor Recycle Bin using Amazon EventBridge \(p. 2063\)](#).

You can unlock a locked Region-level retention rule using one of the following methods.

Recycle Bin console

To unlock a retention rule

1. Open the Recycle Bin console at <https://console.aws.amazon.com/rbin/home/>
2. In the navigation panel, choose **Retention rules**.
3. In the grid, select the locked retention rule to unlock, and choose **Actions, Edit retention rule lock**.
4. On the Edit retention rule lock screen, choose **Unlock**, and then choose **Save**.

AWS CLI

To unlock a locked retention rule

Use the [unlock-rule](#) AWS CLI command. For **--identifier**, specify the ID of the retention rule to unlock.

```
C:\> aws rbin unlock-rule \
--identifier rule_ID
```

Example

The following example command unlocks retention rule 6lsJ2Fa9nh9

```
C:\> aws rbin unlock-rule \
--identifier 6lsJ2Fa9nh9
```

Tag retention rules

You can assign custom tags to your retention rules to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to efficiently find a specific retention rule based on the custom tags that you assigned.

You can assign a tag to a retention rule using one of the following methods.

Recycle Bin console

To tag a retention rule

1. Open the Recycle Bin console at <https://console.aws.amazon.com/rbin/home/>
2. In the navigation pane, choose **Retention rules**.
3. Select the retention rule to tag, choose the **Tags** tab, and then choose **Manage tags**.
4. Choose **Add tag**. For **Key**, enter the tag key. For **Value**, enter the tag value.
5. Choose **Save**.

AWS CLI

To tag a retention rule

Use the [tag-resource](#) AWS CLI command. For **--resource-arn**, specify the Amazon Resource Name (ARN) of the retention rule to tag, and for **--tags**, specify the tag key and value pair.

```
C:\> aws rbin tag-resource \
--resource-arn retention_rule_arn \
--tags key=tag_key,value=tag_value
```

Example

The following example command tags retention rule `arn:aws:rbin:us-east-1:123456789012:rule/n0oSBBtItF3` with tag `purpose=production`.

```
C:\> aws rbin tag-resource \
--resource-arn arn:aws:rbin:us-east-1:123456789012:rule/n0oSBBtItF3 \
--tags key=purpose,value=production
```

View retention rule tags

You can view the tags assigned to a retention rule using one of the following methods.

Recycle Bin console

To view tags for a retention rule

1. Open the Recycle Bin console at <https://console.aws.amazon.com/rbin/home/>
2. In the navigation pane, choose **Retention rules**.
3. Select the retention rule for which to view the tags, and choose the **Tags** tab.

AWS CLI

To view the tags assigned to a retention rule

Use the [list-tags-for-resource](#) AWS CLI command. For `--resource-arn`, specify the ARN of the retention rule.

```
C:\> aws rbin list-tags-for-resource \
--resource-arn retention_rule_arn
```

Example

The following example command lists the tags for retention rule `arn:aws:rbin:us-east-1:123456789012:rule/n0oSBBtItF3`.

```
C:\> aws rbin list-tags-for-resource \
--resource-arn arn:aws:rbin:us-east-1:123456789012:rule/n0oSBBtItF3
```

Remove tags from retention rules

You can remove tags from a retention rule using one of the following methods.

Recycle Bin console

To remove a tag from a retention rule

1. Open the Recycle Bin console at <https://console.aws.amazon.com/rbin/home/>
2. In the navigation pane, choose **Retention rules**.
3. Select the retention rule from which to remove the tag, choose the **Tags** tab, and then choose **Manage tags**.
4. Choose **Remove** next to the tag to remove.
5. Choose **Save**.

AWS CLI

To remove a tag from a retention rule

Use the [untag-resource](#) AWS CLI command. For `--resource-arn`, specify the ARN of the retention rule. For `--tagkeys`, specify the tags keys of the tags to remove.

```
C:\> aws rbin untag-resource \
--resource-arn retention_rule_arn \
--tagkeys tag_key
```

Example

The following example command removes tags that have a tag key of `purpose` from retention rule `arn:aws:rbin:us-east-1:123456789012:rule/n0oSBBtItF3`.

```
C:\> aws rbin untag-resource \
--resource-arn arn:aws:rbin:us-east-1:123456789012:rule/n0oSBBtItF3 \
--tagkeys purpose
```

Delete Recycle Bin retention rules

You can delete a retention rule at any time. When you delete a retention rule, it no longer retains new resources in the Recycle Bin after they have been deleted. Resources that were sent to the Recycle

Bin before the retention rule was deleted continue to be retained in the Recycle Bin according to the retention period defined in the retention rule. When the period expires, the resource is permanently deleted from the Recycle Bin.

You can delete a retention rule using one of the following methods.

Recycle Bin console

To delete a retention rule

1. Open the Recycle Bin console at <https://console.aws.amazon.com/rbin/home/>
2. In the navigation pane, choose **Retention rules**.
3. In the grid, select the retention rule to delete, and choose **Actions, Delete retention rule**.
4. When prompted, enter the confirmation message and choose **Delete retention rule**.

AWS CLI

To delete a retention rule

Use the [delete-rule](#) AWS CLI command. For `--identifier`, specify the ID of the retention rule to delete.

```
C:\> aws rbin delete-rule --identifier rule_ID
```

Example

The following example command deletes retention rule `61sJ2Fa9nh9`.

```
C:\> aws rbin delete-rule --identifier 61sJ2Fa9nh9
```

Work with resources in the Recycle Bin

Recycle Bin supports the following resource types:

- Amazon EBS snapshots
- Amazon EBS-backed Amazon Machine Images (AMIs)

Topics

- [Work with snapshots in the Recycle Bin \(p. 2062\)](#)
- [Work with AMIs in the Recycle Bin \(p. 2062\)](#)

This section includes links to the topics that explain how to work with the supported resource types.

Work with snapshots in the Recycle Bin

For more information about working with snapshots in the Recycle Bin, see [Recover snapshots from the Recycle Bin \(p. 1814\)](#).

Work with AMIs in the Recycle Bin

For more information about working with AMIs in the Recycle Bin, see [Recover AMIs from the Recycle Bin \(p. 189\)](#).

Monitor Recycle Bin

You can use the following features to monitor the Recycle Bin.

Topics

- [Monitor Recycle Bin using Amazon EventBridge \(p. 2063\)](#)
- [Monitor Recycle Bin using AWS CloudTrail \(p. 2065\)](#)

Monitor Recycle Bin using Amazon EventBridge

Recycle Bin sends events to Amazon EventBridge for actions performed on retention rules. With EventBridge, you can establish rules that initiate programmatic actions in response to these events. For example, you can create a EventBridge rule that sends a notification to your email when a retention rule is unlocked and it enters its unlock delay period. For more information, see [Creating Amazon EventBridge rules that react to events](#).

Events in EventBridge are represented as JSON objects. The fields that are unique to the event are contained in the detail section of the JSON object. The event field contains the event name. The result field contains the completed status of the action that initiated the event. For more information, see [Amazon EventBridge event patterns](#) in the *Amazon EventBridge User Guide*.

For more information about Amazon EventBridge, see [What Is Amazon EventBridge?](#) in the *Amazon EventBridge User Guide*.

Events

- [RuleLocked \(p. 2063\)](#)
- [RuleChangeAttempted \(p. 2064\)](#)
- [RuleUnlockScheduled \(p. 2064\)](#)
- [RuleUnlockingNotice \(p. 2064\)](#)
- [RuleUnlocked \(p. 2065\)](#)

RuleLocked

The following is an example of an event that Recycle Bin generates when a retention rule is successfully locked. This event can be generated by **CreateRule** and **LockRule** requests. The API that generated the event is noted in the api-name field.

```
{  
    "version": "0",  
    "id": "exampleb-b491-4cf7-a9f1-bf370example",  
    "detail-type": "Recycle Bin Rule Locked",  
    "source": "aws.rbin",  
    "account": "123456789012",  
    "time": "2022-08-10T16:37:50Z",  
    "region": "us-west-2",  
    "resources": [  
        "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"  
    ],  
    "detail":  
    {  
        "detail-version": "1.0.0",  
        "rule-id": "a12345abcde",  
        "rule-description": "locked account level rule",  
        "unlock-delay-period": "30 days",  
        "api-name": "CreateRule"  
    }  
}
```

```
}
```

RuleChangeAttempted

The following is an example of an event that Recycle Bin generates for unsuccessful attempts to modify or delete a locked rule. This event can be generated by **DeleteRule** and **UpdateRule** requests. The API that generated the event is noted in the `api-name` field.

```
{
  "version": "0",
  "id": "exampleb-b491-4cf7-a9f1-bf370example",
  "detail-type": "Recycle Bin Rule Change Attempted",
  "source": "aws.rbin",
  "account": "123456789012",
  "time": "2022-08-10T16:37:50Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
  ],
  "detail": {
    "detail-version": " 1.0.0",
    "rule-id": "a12345abcde",
    "rule-description": "locked account level rule",
    "unlock-delay-period": "30 days",
    "api-name": "DeleteRule"
  }
}
```

RuleUnlockScheduled

The following is an example of an event that Recycle Bin generates when a retention rule is unlocked and it starts its unlock delay period.

```
{
  "version": "0",
  "id": "exampleb-b491-4cf7-a9f1-bf370example",
  "detail-type": "Recycle Bin Rule Unlock Scheduled",
  "source": "aws.rbin",
  "account": "123456789012",
  "time": "2022-08-10T16:37:50Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
  ],
  "detail": {
    "detail-version": " 1.0.0",
    "rule-id": "a12345abcde",
    "rule-description": "locked account level rule",
    "unlock-delay-period": "30 days",
    "scheduled-unlock-time": "2022-09-10T16:37:50Z",
  }
}
```

RuleUnlockingNotice

The following is an example of an event that Recycle Bin generates daily while a retention rule is in its unlock delay period, until the day before the unlock delay period expires.

```
{
```

```
"version": "0",
"id": "exampleb-b491-4cf7-a9f1-bf370example",
"detail-type": "Recycle Bin Rule Unlocking Notice",
"source": "aws.rbin",
"account": "123456789012",
"time": "2022-08-10T16:37:50Z",
"region": "us-west-2",
"resources": [
    "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
],
"detail": {
    "detail-version": " 1.0.0",
    "rule-id": "a12345abcde",
    "rule-description": "locked account level rule",
    "unlock-delay-period": "30 days",
    "scheduled-unlock-time": "2022-09-10T16:37:50Z"
}
}
```

RuleUnlocked

The following is an example of an event that Recycle Bin generates when the unlock delay period for a retention rule expires and the retention rule can be modified or deleted.

```
{
    "version": "0",
    "id": "exampleb-b491-4cf7-a9f1-bf370example",
    "detail-type": "Recycle Bin Rule Unlocked",
    "source": "aws.rbin",
    "account": "123456789012",
    "time": "2022-08-10T16:37:50Z",
    "region": "us-west-2",
    "resources": [
        "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
    ],
    "detail": {
        "detail-version": " 1.0.0",
        "rule-id": "a12345abcde",
        "rule-description": "locked account level rule",
        "unlock-delay-period": "30 days",
        "scheduled-unlock-time": "2022-09-10T16:37:50Z"
    }
}
```

Monitor Recycle Bin using AWS CloudTrail

The Recycle Bin service is integrated with AWS CloudTrail. CloudTrail is a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls performed in Recycle Bin as events. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon Simple Storage Service (Amazon S3) bucket. If you don't configure a trail, you can still view the most recent management events in the CloudTrail console in **Event history**. You can use the information collected by CloudTrail to determine the request that was made to Recycle Bin, the IP address from which the request was made, who made the request, when it was made, and additional details.

For more information about CloudTrail, see the [AWS CloudTrail User Guide](#).

Recycle Bin information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in Recycle Bin, that activity is recorded in a CloudTrail event along with other AWS service events

in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#).

For an ongoing record of events in your AWS account, including events for Recycle Bin, create a trail. A *trail* enables CloudTrail to deliver log files to an S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see [Overview for creating a trail](#) in the *AWS CloudTrail User Guide*.

Supported API actions

For Recycle Bin, you can use CloudTrail to log the following API actions as *management events*.

- CreateRule
- UpdateRule
- GetRules
- ListRule
- DeleteRule
- TagResource
- UntagResource
- ListTagsForResource
- LockRule
- UnlockRule

For more information about logging management events, see [Logging management events for trails](#) in the *CloudTrail User Guide*.

Identity information

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentityElement](#).

Understand Recycle Bin log file entries

A trail is a configuration that enables delivery of events as log files to an S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following are example CloudTrail log entries.

CreateRule

```
{  
  "eventVersion": "1.08",
```

Resource locations

Amazon EC2 resources are specific to the AWS Region or Availability Zone in which they reside.

Resource	Type	Description
Amazon EC2 resource identifiers	Regional	Each resource identifier, such as an AMI ID, instance ID, EBS volume ID, or EBS snapshot ID, is tied to its Region and can be used only in the Region where you created the resource.
User-supplied resource names	Regional	Each resource name, such as a security group name or key pair name, is tied to its Region and can be used only in the Region where you created the resource. Although you can create resources with the same name in multiple Regions, they aren't related to each other.

Resource	Type	Description
AMIs	Regional	An AMI is tied to the Region where its files are located within Amazon S3. You can copy an AMI from one Region to another. For more information, see Copy an AMI (p. 166) .
EBS snapshots	Regional	An EBS snapshot is tied to its Region and can only be used to create volumes in the same Region. You can copy a snapshot from one Region to another. For more information, see Copy an Amazon EBS snapshot (p. 1781) .
EBS volumes	Availability Zone	An Amazon EBS volume is tied to its Availability Zone and can be attached only to instances in the same Availability Zone.
Elastic IP addresses	Regional	An Elastic IP address is tied to a Region and can be associated only with an instance in the same Region.
Instances	Availability Zone	An instance is tied to the Availability Zones in which you launched it. However, its instance ID is tied to the Region.
Key pairs	Global or Regional	The key pairs that you create using Amazon EC2 are tied to the Region where you created them. You can create your own RSA key pair and upload it to the Region in which you want to use it; therefore, you can make your key pair globally available by uploading it to each Region. For more information, see Amazon EC2 key pairs and Windows instances (p. 1662) .
Security groups	Regional	A security group is tied to a Region and can be assigned only to instances in the same Region. You can't enable an instance to communicate with an instance outside its Region using security group rules. Traffic from an instance in another Region is seen as WAN bandwidth.

Resource IDs

When resources are created, we assign each resource a unique resource ID. A resource ID takes the form of a resource identifier (such as `snap` for a snapshot) followed by a hyphen and a unique combination of letters and numbers.

Each resource identifier, such as an AMI ID, instance ID, EBS volume ID, or EBS snapshot ID, is tied to its Region and can be used only in the Region where you created the resource.

You can use resource IDs to find your resources in the Amazon EC2 console. If you are using a command line tool or the Amazon EC2 API to work with Amazon EC2, resource IDs are required for certain commands. For example, if you are using the [stop-instances](#) AWS CLI command to stop an instance, you must specify the instance ID in the command.

Resource ID length

Prior to January 2016, the IDs assigned to newly created resources of certain resource types used 8 characters after the hyphen (for example, i-1a2b3c4d). From January 2016 to June 2018, we changed the IDs of these resource types to use 17 characters after the hyphen (for example, i-1234567890abcdef0). Depending on when your account was created, you might have some existing resources with short IDs, however, any new resources will receive the longer IDs.

List and filter your resources

You can get a list of some types of resources using the Amazon EC2 console. You can get a list of each type of resource using its corresponding command or API action. If you have many resources, you can filter the results to include, or exclude, only the resources that match certain criteria.

Contents

- [List and filter resources using the console \(p. 2077\)](#)
- [List and filter using the CLI and API \(p. 2081\)](#)
- [List and filter resources across Regions using Amazon EC2 Global View \(p. 2083\)](#)

List and filter resources using the console

Contents

- [List resources using the console \(p. 2077\)](#)
- [Filter resources using the console \(p. 2077\)](#)

List resources using the console

You can view the most common Amazon EC2 resource types using the console. To view additional resources, use the command line interface or the API actions.

To list EC2 resources using the console

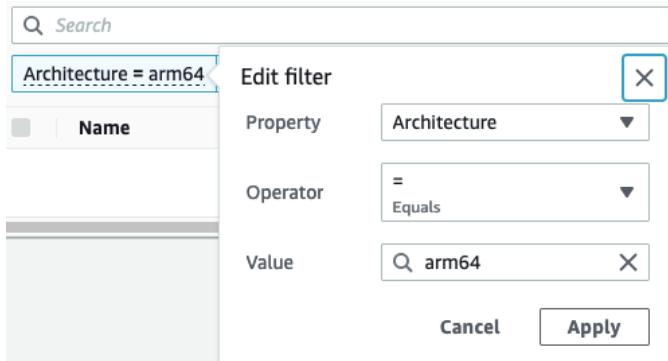

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose the option that corresponds to the resource type. For example, to list your instances, choose **Instances**.

The page displays all resources of the selected resource type.

Filter resources using the console

To filter a list of resources

1. In the navigation pane, select a resource type (for example, **Instances**).
2. Choose the search field.
3. Select the filter from the list.
4. Select an operator, for example, **= (Equals)**. Some attributes have more available operators to select. Note that not all screens support selecting an operator.
5. Select a filter value.
6. To edit a selected filter, choose the filter token (blue box), make the required edits, and then choose **Apply**. Note that not all screens support editing the selected filter.

7. When you are finished, remove the filter.

The search and filter functionality differs slightly between the *old* and *new* Amazon EC2 console.

New console

The new console supports two types of filtering.

- *API filtering* happens on the server side. The filtering is applied on the API call, which reduces the number of resources returned by the server. It allows for quick filtering across large sets of resources, and it can reduce data transfer time and cost between the server and the browser. API filtering supports `=` (equals) and `:` (contains) operators, and is always case sensitive.
- *Client filtering* happens on the client side. It enables you to filter down on data that is already available in the browser (in other words, data that has already been returned by the API). Client filtering works well in conjunction with an API filter to filter down to smaller data sets in the browser. In addition to `=` (equals) and `:` (contains) operators, client filtering can also support range operators, such as `>=` (greater than or equal), and negation (inverse) operators, such as `!=` (does not equal).

The new Amazon EC2 console supports the following types of searches:

Search by keyword

Searching by keyword is a free text search that lets you search for a value across all of your resources' attributes or tags, without specifying an attribute or tag key to search.

Note

All keyword searches use *client filtering*.

To search by keyword, enter or paste what you're looking for in the search field, and then choose **Enter**. For example, searching for 123 matches all instances that have 123 in any of their attributes, such as an IP address, instance ID, VPC ID, or AMI ID, or in any of their tags, such as the Name. If your free text search returns unexpected matches, apply additional filters.

Search by attribute

Searching by an attribute lets you search a specific attribute across all of your resources.

Note

Attribute searches use either *API filtering* or *client filtering*, depending on the selected attribute. When performing an attribute search, the attributes are grouped accordingly.

For example, you can search the **Instance state** attribute for all of your instances to return only instances that are in the stopped state. To do this:

1. In the search field on the **Instances** screen, start entering `Instance state`. As you enter the characters, the two types of filters appear for **Instance state**: **API filters** and **Client filters**.

2. To search on the server side, choose **Instance state** under **API filters**. To search on the client side, choose **Instance state (client)** under **Client filters**.

A list of possible operators for the selected attribute appears.

3. Choose the **= (Equals)** operator.

A list of possible values for the selected attribute and operator appears.

4. Choose **stopped** from the list.

Search by tag

Searching by a tag lets you filter the resources in the currently displayed table by a tag key or a tag value.

Tag searches use either *API filtering* or *client filtering*, depending on the settings in the Preferences window.

To ensure API filtering for tags

1. Open the **Preferences** window.
2. Clear the **Use regular expression matching** check box. If this check box is selected, client filtering is performed.
3. Select the **Use case sensitive matching** check box. If this check box is cleared, client filtering is performed.
4. Choose **Confirm**.

When searching by tag, you can use the following values:

- **(empty)** – Find all resources with the specified tag key, but there must be no tag value.
- **All values** – Find all resources with the specified tag key and any tag value.
- **Not tagged** – Find all resources that do not have the specified tag key.
- **The displayed value** – Find all resources with the specified tag key and the specified tag value.

You can use the following techniques to enhance or refine your searches:

Inverse search

Inverse searches let you search for resources that do **not** match a specified value. In the **Instances** and **AMIs** screens, inverse searches are performed by selecting the **!= (Does not equal)** or **!: (Does not contain)** operator and then selecting a value. In other screens, inverse searches are performed by prefixing the search keyword with the exclamation mark (!) character.

Note

Inverse search is supported with keyword searches and attribute searches on *client filters* only. It is not supported with attribute searches on API filters.

For example, you can search the **Instance state** attribute for all of your instances to exclude all instances that are in the terminated state. To do this:

1. In the search field on the **Instances** screen, start entering **Instance state**. As you enter the characters, the two types of filters appear for **Instance state**: **API filters** and **Client filters**.
2. Under **Client filters**, choose **Instance state (client)**. Inverse search is only supported on *client filters*.

A list of possible operators for the selected attribute appears.

3. Choose **!= (Does not equal)**, and then choose **terminated**.

To filter instances based on an instance state attribute, you can also use the search icons (

) in the **Instance state** column. The search icon with a plus sign (+) displays all the instances that *match* that attribute. The search icon with a minus sign (-) *excludes* all instances that match that attribute.

Here is another example of using the inverse search: To list all instances that are **not** assigned the security group named launch-wizard-1, under **Client filters**, search by the **Security group name** attribute, choose !=, and in the search bar, enter launch-wizard-1.

Partial search

With partial searches, you can search for partial string values. To perform a partial search, enter only a part of the keyword that you want to search for. On the **Instances** and **AMIs** screens, partial searches can only be performed with the : (Contains) operator. On other screens, you can select the client filter attribute and immediately enter only a part of the keyword that you want to search for. For example, on the **Instance type** screen, to search for all t2.micro, t2.small, and t2.medium instances, search by the **Instance Type** attribute, and for the keyword, enter t2.

Regular expression search

To use regular expression searches, you must select the **Use regular expression matching** check box in the Preferences window.

Regular expressions are useful when you need to match the values in a field with a specific pattern. For example, to search for a value that starts with s, search for ^s. To search for a value that ends with xyz, search for xyz\$. Or to search for a value that starts with a number that is followed by one or more characters, search for [0-9]+.*.

Note

Regular expression search is supported with keyword searches and attribute searches on client filters only. It is not supported with attribute searches on API filters.

Case-sensitive search

To use case-sensitive searches, you must select the **Use case sensitive matching** check box in the **Preferences** window. The case-sensitive preference only applies to client and tag filters.

Note

API filters are always case-sensitive.

Wildcard search

Use the * wildcard to match zero or more characters. Use the ? wildcard to match zero or one character. For example, if you have a data set with the values prod, prods, and production, a search of prod* matches all values, whereas prod? matches only prod and prods. To use the literal values, escape them with a backslash (\). For example, "prod*" would match prod*.

Note

Wildcard search is supported with attribute and tag searches on API filters only. It is not supported with keyword searches, and with attribute and tag searches on client filters.

Combining searches

In general, multiple filters with the same attribute are automatically joined with OR. For example, searching for **Instance State** : Running and **Instance State** : Stopped returns all instances that are either running OR stopped. To join search with AND, search across different attributes. For example, searching for **Instance State** : Running and **Instance Type** : c4.large returns only instances that are of type c4.large AND that are in the running state.

Old console

The old Amazon EC2 console supports the following types of searches:

Search by keyword

Searching by keyword is a free text search that lets you search for a value across all of your resources' attributes. To search by keyword, enter or paste what you're looking for in the search field, and then choose **Enter**. For example, searching for 123 matches all instances that have 123 in any of their attributes, such as an IP address, instance ID, VPC ID, or AMI ID. If your free text search returns unexpected matches, apply additional filters.

Search by attributes

Searching by an attribute lets you search a specific attribute across all of your resources. For example, you can search the **State** attribute for all of your instances to return only instances that are in the stopped state. To do this:

1. In the search field on the Instances screen, start entering **Instance State**. As you enter characters, a list of matching attributes appears.
2. Select **Instance State** from the list. A list of possible values for the selected attribute appears.
3. Select **Stopped** from the list.

You can use the following techniques to enhance or refine your searches:

Inverse search

Inverse searches let you search for resources that do **not** match a specified value. Inverse searches are performed by prefixing the search keyword with the exclamation mark (!) character. For example, to list all instances that are **not** terminated, search by the **Instance State** attribute, and for the keyword, enter !Terminated.

Partial search

With partial searches, you can search for partial string values. To perform a partial search, enter only a part of the keyword you want to search for. For example, to search for all t2.micro, t2.small, and t2.medium instances, search by the **Instance Type** attribute, and for the keyword, enter t2.

Regular expression search

Regular expressions are useful when you need to match the values in a field with a specific pattern. For example, to search for all instances that have an attribute value that starts with s, search for ^s. Or to search for all instances that have an attribute value that ends with xyz, search for xyz\$. Regular expression searches are not case-sensitive.

Combining searches

In general, multiple filters with the same attribute are automatically joined with OR. For example, searching for **Instance State : Running** and **Instance State : Stopped** returns all instances that are either running OR stopped. To join search with AND, search across different attributes. For example, searching for **Instance State : Running** and **Instance Type : c4.large** returns only instances that are of type c4.large AND that are in the stopped state.

List and filter using the CLI and API

Each resource type has a corresponding CLI command and API action that you use to list resources of that type. The resulting lists of resources can be long, so it can be faster and more useful to filter the results to include only the resources that match specific criteria.

Filtering considerations

- You can specify multiple filters and multiple filter values in a single request.
- You can use wildcards with the filter values. An asterisk (*) matches zero or more characters, and a question mark (?) matches zero or one character.

- Filter values are case sensitive.
- Your search can include the literal values of the wildcard characters; you just need to escape them with a backslash before the character. For example, a value of *amazon\?\\\ searches for the literal string *amazon?\.

Supported filters

To see the supported filters for each Amazon EC2 resource, see the following documentation:

- AWS CLI: The describe commands in the [AWS CLI Command Reference-Amazon EC2](#).
- Tools for Windows PowerShell: The Get commands in the [AWS Tools for PowerShell Cmdlet Reference-Amazon EC2](#).
- Query API: The Describe API actions in the [Amazon EC2 API Reference](#).

Example Example: Specify a single filter

You can list your Amazon EC2 instances using [describe-instances](#). Without filters, the response contains information for all of your resources. You can use the following command to include only the running instances in your output.

```
aws ec2 describe-instances --filters Name=instance-state-name,Values=running
```

To list only the instance IDs for your running instances, add the --query parameter as follows.

```
aws ec2 describe-instances --filters Name=instance-state-name,Values=running --query "Reservations[*].Instances[*].InstanceId" --output text
```

The following is example output.

```
i-0ef1f57f78d4775a4
i-0626d4edd54f1286d
i-04a636d18e83cfacb
```

Example Example: Specify multiple filters or filter values

If you specify multiple filters or multiple filter values, the resource must match all filters to be included in the results.

You can use the following command to list all instances whose type is either m5.large or m5d.large.

```
aws ec2 describe-instances --filters Name=instance-type,Values=m5.large,m5d.large
```

You can use the following command to list all stopped instances whose type is t2.micro.

```
aws ec2 describe-instances --filters Name=instance-state-name,Values=stopped Name=instance-type,Values=t2.micro
```

Example Example: Use wildcards in a filter value

If you specify database as the filter value for the description filter when describing EBS snapshots using [describe-snapshots](#), the command returns only the snapshots whose description is "database".

```
aws ec2 describe-snapshots --filters Name=description,Values=database
```

The * wildcard matches zero or more characters. If you specify *database* as the filter value, the command returns only snapshots whose description includes the word database.

```
aws ec2 describe-snapshots --filters Name=description,Values=*database*
```

The ? wildcard matches exactly 1 character. If you specify database? as the filter value, the command returns only snapshots whose description is "database" or "database" followed by one character.

```
aws ec2 describe-snapshots --filters Name=description,Values=database?
```

If you specify database????, the command returns only snapshots whose description is "database" followed by up to four characters. It excludes descriptions with "database" followed by five or more characters.

```
aws ec2 describe-snapshots --filters Name=description,Values=database????
```

Example Example: Filter based on date

With the AWS CLI, you can use JMESPath to filter results using expressions. For example, the following [describe-snapshots](#) command displays the IDs of all snapshots created by your AWS account (represented by `123456789012`) before the specified date (represented by `2020-03-31`). If you do not specify the owner, the results include all public snapshots.

```
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[?(StartTime<='2020-03-31')].[SnapshotId]" --output text
```

The following command displays the IDs of all snapshots created in the specified date range.

```
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[?(StartTime>='2019-01-01') && (StartTime<='2019-12-31')].[SnapshotId]" --output text
```

Filter based on tags

For examples of how to filter a list of resources according to their tags, see [Work with tags using the command line \(p. 2094\)](#).

List and filter resources across Regions using Amazon EC2 Global View

Amazon EC2 Global View enables you to view some of your Amazon EC2 and Amazon VPC resources across a single AWS Region, or across multiple Regions in a single console. Amazon EC2 Global View also provides *global search* functionality that lets you search for specific resources or specific resource types across multiple Regions simultaneously.

Amazon EC2 Global View does not let you modify resources in any way.

Supported resources

Using Amazon EC2 Global View, you can view a global summary of the following resources across all of the Regions for which your AWS account is enabled.

- VPCs
- Subnets

- Security groups
- Volumes
- Auto Scaling groups
- Egress-only internet gateways
- Internet gateways
- NAT gateways
- Route tables
- VPC endpoints

Required permissions

A user must have the following permissions to use Amazon EC2 Global View.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ec2:DescribeInstances",  
                "ec2:DescribeVpcs",  
                "ec2:DescribeRegions",  
                "ec2:DescribeVolumes",  
                "ec2:DescribeSubnets",  
                "ec2:DescribeSecurityGroups",  
                "ec2:DescribeRouteTables",  
                "ec2:DescribeVpcEndpoints",  
                "ec2:DescribeNatGateways",  
                "ec2:DescribeInternetGateways",  
                "ec2:DescribeEgressOnlyInternetGateways",  
                "autoscaling:DescribeAutoScalingGroups"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

To use Amazon EC2 Global View

Open the Amazon EC2 Global View console at <https://console.aws.amazon.com/ec2globalview/home>.

Important

You cannot use a private window in Firefox to access Amazon EC2 Global View.

The console consists of two tabs:

- **Region explorer**—This tab includes the following sections:
 - **Resource summary**—Provides a high-level overview of your resources across all Regions.

Enabled Regions indicates the number of Regions for which your AWS account is enabled. The remaining fields indicate the number of resources that you currently have in those Regions. Choose any of the links to view the resources of that type across all Regions. For example, if the link below the **Instances** label is **29 in 10 Regions**, it indicates that you currently have 29 instances across 10 Regions. Choose the link to view a list of all 29 instances.

- **Resource counts per Region**—Lists all of the AWS Regions (including those for which your account is not enabled) and provides totals for each resource type for each Region.

Choose a Region name to view all resources of all types for that specific Region. For example, choose **Africa (Cape Town) af-south-1** to view all VPCs, subnets, instances, security groups, volumes, and

Auto Scaling groups in that Region. Alternatively, select a Region and choose **View resources for selected Region**.

Choose the value for a specific resource type in a specific Region to view only resources of that type in that Region. For example, choose the value for Instances for **Africa (Cape Town) af-south-1** to view only the instances in that Region.

- **Global search**—This tab enables you to search for specific resources or specific resource types across a single Region or across multiple Regions. It also enables you to view details for a specific resource.

To search for resources, enter the search criteria in the field preceding the grid. You can search by Region, by resource type, and by the tags assigned to resources.

To view the details for a specific resource, select it in the grid. You can also choose the resource ID of a resource to open it in its respective console. For example, choose an instance ID to open the instance in the Amazon EC2 console, or choose a subnet ID to open the subnet in the Amazon VPC console.

Tag your Amazon EC2 resources

To help you manage your instances, images, and other Amazon EC2 resources, you can assign your own metadata to each resource in the form of *tags*. Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. This is useful when you have many resources of the same type—you can quickly identify a specific resource based on the tags that you've assigned to it. This topic describes tags and shows you how to create them.

Warning

Tag keys and their values are returned by many different API calls. Denying access to `DescribeTags` doesn't automatically deny access to tags returned by other APIs. As a best practice, we recommend that you do not include sensitive data in your tags.

Contents

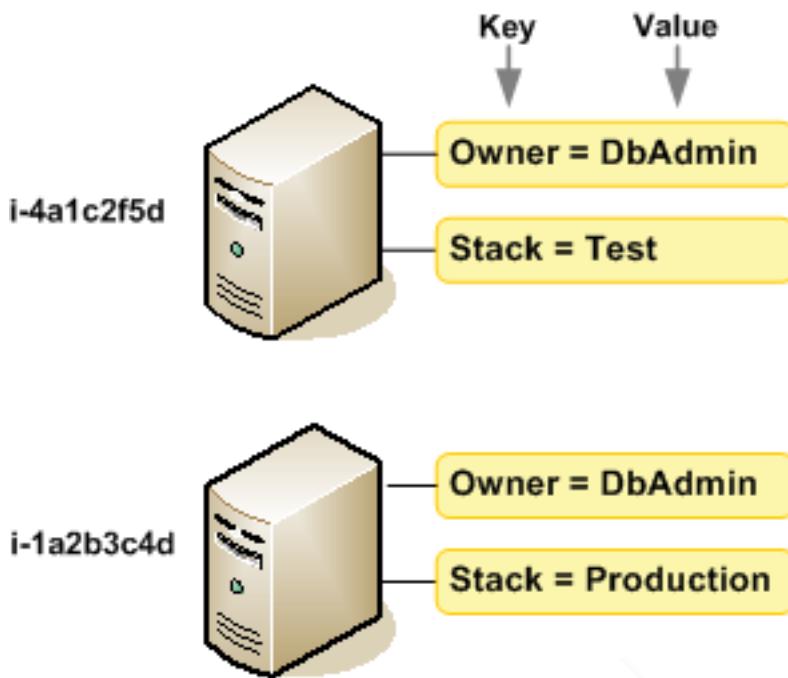

- [Tag basics \(p. 2085\)](#)
- [Tag your resources \(p. 2086\)](#)
- [Tag restrictions \(p. 2089\)](#)
- [Tags and access management \(p. 2090\)](#)
- [Tag your resources for billing \(p. 2090\)](#)
- [Work with tags using the console \(p. 2090\)](#)
- [Work with tags using the command line \(p. 2094\)](#)
- [Work with instance tags in instance metadata \(p. 2097\)](#)
- [Add tags to a resource using CloudFormation \(p. 2099\)](#)

Tag basics

A tag is a label that you assign to an AWS resource. Each tag consists of a *key* and an optional *value*, both of which you define.

Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. For example, you could define a set of tags for your account's Amazon EC2 instances that helps you track each instance's owner and stack level.

The following diagram illustrates how tagging works. In this example, you've assigned two tags to each of your instances—one tag with the key `Owner` and another with the key `Stack`. Each tag also has an associated value.

We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter the resources based on the tags you add. For more information about how to implement an effective resource tagging strategy, see the [Tagging Best Practices AWS Whitepaper](#).

Tags don't have any semantic meaning to Amazon EC2 and are interpreted strictly as a string of characters. Also, tags are not automatically assigned to your resources. You can edit tag keys and values, and you can remove tags from a resource at any time. You can set the value of a tag to an empty string, but you can't set the value of a tag to null. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value. If you delete a resource, any tags for the resource are also deleted.

Note

After you delete a resource, its tags might remain visible in the console, API, and CLI output for a short period. These tags will be gradually disassociated from the resource and be permanently deleted.

Tag your resources

You can tag most Amazon EC2 resources that already exist in your account. The following [table \(p. 2087\)](#) lists the resources that support tagging.

If you're using the Amazon EC2 console, you can apply tags to resources by using the **Tags** tab on the relevant resource screen, or you can use the **Tags Editor** in the AWS Resource Groups console. Some resource screens enable you to specify tags for a resource when you create the resource; for example, a tag with a key of Name and a value that you specify. In most cases, the console applies the tags immediately after the resource is created (rather than during resource creation). The console might organize resources according to the Name tag, but this tag doesn't have any semantic meaning to the Amazon EC2 service.

If you're using the Amazon EC2 API, the AWS CLI, or an AWS SDK, you can use the [CreateTags EC2 API](#) action to apply tags to existing resources. Additionally, some resource-creating actions enable you to specify tags for a resource when the resource is created. If tags cannot be applied during resource creation, we roll back the resource creation process. This ensures that resources are either created with tags or not created at all, and that no resources are left untagged at any time. By tagging resources at the time of creation, you can eliminate the need to run custom tagging scripts after resource creation. For more information about enabling users to tag resources on creation, see [Grant permission to tag resources during creation \(p. 1599\)](#).

The following table describes the Amazon EC2 resources that can be tagged, and the resources that can be tagged on creation using the Amazon EC2 API, the AWS CLI, or an AWS SDK.

Tagging support for Amazon EC2 resources

Resource	Supports tags	Supports tagging on creation
AFI	Yes	Yes
AMI	Yes	Yes
Bundle task	No	No
Capacity Reservation	Yes	Yes
Carrier gateway	Yes	Yes
Client VPN endpoint	Yes	Yes
Client VPN route	No	No
Customer gateway	Yes	Yes
Dedicated Host	Yes	Yes
Dedicated Host Reservation	Yes	Yes
DHCP options	Yes	Yes
EBS snapshot	Yes	Yes
EBS volume	Yes	Yes
EC2 Fleet	Yes	Yes
Egress-only internet gateway	Yes	Yes
Elastic IP address	Yes	Yes
Elastic Graphics accelerator	Yes	No
Instance	Yes	Yes
Instance event window	Yes	Yes
Instance store volume	N/A	N/A
Internet gateway	Yes	Yes
IP address pool (BYOIP)	Yes	Yes
Key pair	Yes	Yes
Launch template	Yes	Yes

Resource	Supports tags	Supports tagging on creation
Launch template version	No	No
Local gateway	Yes	No
Local gateway route table	Yes	No
Local gateway virtual interface	Yes	No
Local gateway virtual interface group	Yes	No
Local gateway route table VPC association	Yes	Yes
Local gateway route table virtual interface group association	Yes	No
NAT gateway	Yes	Yes
Network ACL	Yes	Yes
Network interface	Yes	Yes
Placement group	Yes	Yes
Prefix list	Yes	Yes
Reserved Instance	Yes	No
Reserved Instance listing	No	No
Route table	Yes	Yes
Spot Fleet request	Yes	Yes
Spot Instance request	Yes	Yes
Security group	Yes	Yes
Security group rule	Yes	No
Subnet	Yes	Yes
Traffic Mirror filter	Yes	Yes
Traffic Mirror session	Yes	Yes
Traffic Mirror target	Yes	Yes
Transit gateway	Yes	Yes
Transit gateway multicast domain	Yes	Yes
Transit gateway route table	Yes	Yes
Transit gateway VPC attachment	Yes	Yes
Virtual private gateway	Yes	Yes
VPC	Yes	Yes

Resource	Supports tags	Supports tagging on creation
VPC endpoint	Yes	Yes
VPC endpoint service	Yes	Yes
VPC endpoint service configuration	Yes	Yes
VPC flow log	Yes	Yes
VPC peering connection	Yes	Yes
VPN connection	Yes	Yes

You can tag instances, volumes, elastic graphics, network interfaces, and Spot Instance requests on creation using the Amazon EC2 [launch instance wizard \(p. 554\)](#) in the Amazon EC2 console. You can tag your EBS volumes on creation using the **Volumes** screen, or EBS snapshots using the **Snapshots** screen. Alternatively, use the resource-creating Amazon EC2 APIs (for example, [RunInstances](#)) to apply tags when creating your resource.

You can apply tag-based resource-level permissions in your IAM policies to the Amazon EC2 API actions that support tagging on creation to implement granular control over the users and groups that can tag resources on creation. Your resources are properly secured from creation—tags are applied immediately to your resources, therefore any tag-based resource-level permissions controlling the use of resources are immediately effective. Your resources can be tracked and reported on more accurately. You can enforce the use of tagging on new resources, and control which tag keys and values are set on your resources.

You can also apply resource-level permissions to the `CreateTags` and `DeleteTags` Amazon EC2 API actions in your IAM policies to control which tag keys and values are set on your existing resources. For more information, see [Example: Tag resources \(p. 1631\)](#).

For more information about tagging your resources for billing, see [Using cost allocation tags](#) in the *AWS Billing User Guide*.

Tag restrictions

The following basic restrictions apply to tags:

- Maximum number of tags per resource – 50
- For each resource, each tag key must be unique, and each tag key can have only one value.
- Maximum key length – 128 Unicode characters in UTF-8
- Maximum value length – 256 Unicode characters in UTF-8
- Allowed characters
 - Although EC2 allows for any character in its tags, other services are more restrictive. The allowed characters across services are: letters (a-z, A-Z), numbers (0-9), and spaces representable in UTF-8, and the following characters: + - = . _ : / @.
 - If you enable instance tags in instance metadata, instance tag keys can only use letters (a-z, A-Z), numbers (0-9), and the following characters: + - = . , _ : @. Instance tag keys can't contain spaces or /, and can't comprise only . (one period), .. (two periods), or _index. For more information, see [Work with instance tags in instance metadata \(p. 2097\)](#).
- Tag keys and values are case-sensitive.
- The aws: prefix is reserved for AWS use. If a tag has a tag key with this prefix, then you can't edit or delete the tag's key or value. Tags with the aws: prefix do not count against your tags per resource limit.

You can't terminate, stop, or delete a resource based solely on its tags; you must specify the resource identifier. For example, to delete snapshots that you tagged with a tag key called DeleteMe, you must use the DeleteSnapshots action with the resource identifiers of the snapshots, such as snap-1234567890abcdef0.

When you tag public or shared resources, the tags you assign are available only to your AWS account; no other AWS account will have access to those tags. For tag-based access control to shared resources, each AWS account must assign its own set of tags to control access to the resource.

You can't tag all resources. For more information, see [Tagging support for Amazon EC2 resources \(p. 2087\)](#).

Tags and access management

If you're using AWS Identity and Access Management (IAM), you can control which users in your AWS account have permission to create, edit, or delete tags. For more information, see [Grant permission to tag resources during creation \(p. 1599\)](#).

You can also use resource tags to implement attribute-based control (ABAC). You can create IAM policies that allow operations based on the tags for the resource. For more information, see [Control access to EC2 resources using resource tags \(p. 1601\)](#).

Tag your resources for billing

You can use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. For more information about setting up a cost allocation report with tags, see [Monthly cost allocation report](#) in the *AWS Billing User Guide*. To see the cost of your combined resources, you can organize your billing information based on resources that have the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see [Using cost allocation tags](#) in the *AWS Billing User Guide*.

Note

If you've just enabled reporting, data for the current month is available for viewing after 24 hours.

Cost allocation tags can indicate which resources are contributing to costs, but deleting or deactivating resources doesn't always reduce costs. For example, snapshot data that is referenced by another snapshot is preserved, even if the snapshot that contains the original data is deleted. For more information, see [Amazon Elastic Block Store volumes and snapshots](#) in the *AWS Billing User Guide*.

Note

Elastic IP addresses that are tagged do not appear on your cost allocation report.

Work with tags using the console

You can use the Amazon EC2 console to display the tags of an individual resource, and to apply or remove tags from one resource at a time.

You can use the **Tag Editor** in the AWS Resource Groups console to display the tags of all of your Amazon EC2 resources across all Regions. You can view tags by resource and by resource type, and you can see which resource types are associated with a specified tag. You can apply or remove tags from multiple resources and multiple resource types at a time. The **Tag Editor** provides a central, unified way to create and manage your tags. For more information, see the [Tagging AWS Resources User Guide](#).

Tasks

- [Display tags \(p. 2091\)](#)
- [Add and delete tags on an individual resource \(p. 2091\)](#)
- [Add and delete tags for multiple resources \(p. 2092\)](#)
- [Add a tag when you launch an instance \(p. 2093\)](#)
- [Filter a list of resources by tag \(p. 2094\)](#)

Display tags

You can display the tags of an individual resource in the Amazon EC2 console. To display the tags of all your resources, use the **Tag Editor** in the AWS Resource Groups console.

Display tags of an individual resource

When you select a resource-specific page in the Amazon EC2 console, it displays a list of those resources. For example, if you select **Instances** from the navigation pane, the console displays your Amazon EC2 instances. When you select a resource from one of these lists (for example, an instance), if the resource supports tags, you can view and manage its tags. On most resource pages, you can view the tags by choosing the **Tags** tab.

You can add a column to the resource list to display all values for tags with the same key. You can use this column to sort and filter the resource list by the tag.

New console

To add a column to the resource list to display your tags

1. In the EC2 console, choose the **Preferences** gear-shaped icon in the top right corner of the screen.
2. In the **Preferences** dialog box, for **Tag columns** (at bottom left), select one or more tag keys, and then choose **Confirm**.

Old console

There are two ways to add a new column to the resource list to display your tags:

- On the **Tags** tab, select **Show Column**. A new column is added to the console.
- Choose the **Show/Hide Columns** gear-shaped icon, and in the **Show/Hide Columns** dialog box, select the tag key under **Your Tag Keys**.

Display tags for multiple resources

You can display tags across multiple resources by using the **Tag Editor** in the [AWS Resource Groups console](#). For more information, see the [Tagging AWS Resources User Guide](#).

Add and delete tags on an individual resource

You can manage tags for an individual resource directly from the resource's page.

To add a tag to an individual resource

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region where the resource to tag is located. For more information, see [Resource locations \(p. 2075\)](#).

3. In the navigation pane, select a resource type (for example, **Instances**).
4. Select the resource from the resource list and choose the **Tags** tab.
5. Choose **Manage tags**, and then choose **Add new tag**. Enter the key and value for the tag. Choose **Add new tag** again for each additional tag to add. When you are finished adding tags, choose **Save**.

To delete a tag from an individual resource

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region where the resource to untag is located. For more information, see [Resource locations \(p. 2075\)](#).
3. In the navigation pane, choose a resource type (for example, **Instances**).
4. Select the resource from the resource list and choose the **Tags** tab.
5. Choose **Manage tags**. For each tag to remove, choose **Remove**. When you are finished removing tags, choose **Save**.

Add and delete tags for multiple resources

To add a tag to multiple resources

1. Open the **Tag Editor** in the AWS Resource Groups console at <https://console.aws.amazon.com/resource-groups/tag-editor>.
2. For **Regions**, select one or more Regions where the resources to tag are located.
3. For **Resource types**, select the type of resources to tag (for example, **AWS::EC2::Instance**).
4. Choose **Search resources**.
5. Under **Resource search results**, select the check box next to each resource to tag.
6. Choose **Manage tags of selected resources**.
7. Under **Edit tags of all selected resources**, choose **Add tag**, and then enter the new tag key and value. Choose **Add tag** again for each additional tag to add.

Note

If you add a new tag with the same tag key as an existing tag, the new tag overwrites the existing tag.

8. Choose **Review and apply tag changes**.
9. Choose **Apply changes to all selected**.

To remove a tag from multiple resources

1. Open the **Tag Editor** in the AWS Resource Groups console at <https://console.aws.amazon.com/resource-groups/tag-editor>.
2. For **Regions**, select the Regions where the resources to untag are located.
3. For **Resource types**, select the type of resources to untag (for example, **AWS::EC2::Instance**).
4. Choose **Search resources**.
5. Under **Resource search results**, select the check box next to each resource to untag.
6. Choose **Manage tags of selected resources**.
7. Under **Edit tags of all selected resources**, next to the tag to remove, choose **Remove tag**.
8. Choose **Review and apply tag changes**.
9. Choose **Apply changes to all selected**.

Add a tag when you launch an instance

New console

To add a tag using the launch instance wizard

1. From the navigation bar, select the Region for the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. Select the Region that meets your needs. For more information, see [Resource locations \(p. 2075\)](#).
2. Choose **Launch instance**.
3. Under **Name and tags**, you can enter a descriptive name for your instance and specify tags.

The instance name is a tag, where the key is **Name**, and the value is the name that you specify. You can tag the instance, volumes, elastic graphics, and network interfaces. For Spot Instances, you can tag the Spot Instance request only.

Specifying an instance name and additional tags is optional.

- For **Name**, enter a descriptive name for the instance. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.
 - To add additional tags, choose **Add additional tags**. Choose **Add tag**, and then enter a key and value, and select the resource type to tag. Choose **Add tag** again for each additional tag to add.
4. Under **Application and OS Images (Amazon Machine Image)**, choose the operating system (OS) for your instance and an AMI. For more information, see [Application and OS Images \(Amazon Machine Image\) \(p. 555\)](#).
 5. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one.
 6. Either keep all the other fields at their default values or choose specific values for your desired instance configuration. For information about the fields, see [Launch an instance using defined parameters \(p. 554\)](#).
 7. In the **Summary** panel, review your settings, and then choose **Launch instance**.

Old console

To add a tag using the launch instance wizard

1. From the navigation bar, select the Region for the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. Select the Region that meets your needs. For more information, see [Resource locations \(p. 2075\)](#).
2. Choose **Launch Instance**.
3. The **Choose an Amazon Machine Image (AMI)** page displays a list of basic configurations called Amazon Machine Images (AMIs). Select the AMI to use and choose **Select**. For more information, see [Find a Windows AMI \(p. 123\)](#).
4. On the **Configure Instance Details** page, configure the instance settings as necessary, and then choose **Next: Add Storage**.
5. On the **Add Storage** page, you can specify additional storage volumes for your instance. Choose **Next: Add Tags** when done.
6. On the **Add Tags** page, specify tags for the instance, the volumes, or both. Choose **Add another tag** to add more than one tag to your instance. Choose **Next: Configure Security Group** when you are done.
7. On the **Configure Security Group** page, you can choose from an existing security group that you own, or let the wizard create a new security group for you. Choose **Review and Launch** when you are done.

8. Review your settings. When you're satisfied with your selections, choose **Launch**. Select an existing key pair or create a new one, select the acknowledgment check box, and then choose **Launch Instances**.

Filter a list of resources by tag

You can filter your list of resources based on one or more tag keys and tag values.

To filter a list of resources by tag in the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, select a resource type (for example, **Instances**).
3. Choose the search field.
4. In the list, under **Tags**, choose the tag key.
5. Choose the corresponding tag value from the list.
6. When you are finished, remove the filter.

For more information about using filters in the Amazon EC2 console, see [List and filter your resources \(p. 2077\)](#).

To filter multiple resources across multiple Regions by tag using the Tag Editor

You can use the **Tag Editor** in the AWS Resource Groups console to filter multiple resources across multiple Regions by tag. For more information, see [Finding resources to tag](#) in the *Tagging AWS Resources User Guide*.

Work with tags using the command line

You can add tags to many EC2 resources when you create them, using the tag specifications parameter for the create command. You can view the tags for a resource using the describe command for the resource. You can also add, update, or delete tags for your existing resources using the following commands.

Task	AWS CLI	AWS Tools for Windows PowerShell
Add or overwrite one or more tags	create-tags	New-EC2Tag
Delete one or more tags	delete-tags	Remove-EC2Tag
Describe one or more tags	describe-tags	Get-EC2Tag

Tasks

- [Add tags on resource creation \(p. 2094\)](#)
- [Add tags to an existing resource \(p. 2095\)](#)
- [Describe tagged resources \(p. 2096\)](#)

Add tags on resource creation

The following examples demonstrate how to apply tags when you create resources.

Note

The way you enter JSON-formatted parameters on the command line differs depending on your operating system.

- Linux, macOS, or Unix and Windows PowerShell – Use single quotes ('') to enclose the JSON data structure.
- Windows – Omit the single quotes when using the commands with the Windows command line.

For more information, see [Specifying parameter values for the AWS CLI](#).

Example Example: Launch an instance and apply tags to the instance and volume

The following [run-instances](#) command launches an instance and applies a tag with the key **webserver** and the value **production** to the instance. The command also applies a tag with the key **cost-center** and the value **cc123** to any EBS volume that's created (in this case, the root volume).

```
aws ec2 run-instances \
--image-id ami-abc12345 \
--count 1 \
--instance-type t2.micro \
--key-name MyKeyPair \
--subnet-id subnet-6e7f829e \
--tag-specifications 'ResourceType=instance,Tags=[{Key=webserver,Value=production}]' \
'ResourceType=volume,Tags=[{Key=cost-center,Value=cc123}]'
```

You can apply the same tag keys and values to both instances and volumes during launch. The following command launches an instance and applies a tag with a key of **cost-center** and a value of **cc123** to both the instance and any EBS volume that's created.

```
aws ec2 run-instances \
--image-id ami-abc12345 \
--count 1 \
--instance-type t2.micro \
--key-name MyKeyPair \
--subnet-id subnet-6e7f829e \
--tag-specifications 'ResourceType=instance,Tags=[{Key=cost-center,Value=cc123}]' \
'ResourceType=volume,Tags=[{Key=cost-center,Value=cc123}]'
```

Example Example: Create a volume and apply a tag

The following [create-volume](#) command creates a volume and applies two tags: **purpose=production** and **cost-center=cc123**.

```
aws ec2 create-volume \
--availability-zone us-east-1a \
--volume-type gp2 \
--size 80 \
--tag-specifications 'ResourceType=volume,Tags=[{Key=purpose,Value=production}, \
{Key=cost-center,Value=cc123}]'
```

Add tags to an existing resource

The following examples demonstrate how to add tags to an existing resource using the [create-tags](#) command.

Example Example: Add a tag to a resource

The following command adds the tag **Stack=production** to the specified image, or overwrites an existing tag for the AMI where the tag key is **Stack**. If the command succeeds, no output is returned.

```
aws ec2 create-tags \
--resources ami-78a54011 \
--tags Key=Stack,Value=production
```

Example Example: Add tags to multiple resources

This example adds (or overwrites) two tags for an AMI and an instance. One of the tags contains just a key (**webserver**), with no value (we set the value to an empty string). The other tag consists of a key (**stack**) and value (**Production**). If the command succeeds, no output is returned.

```
aws ec2 create-tags \
--resources ami-1a2b3c4d i-1234567890abcdef0 \
--tags Key=webserver,Value= Key=stack,Value=Production
```

Example Example: Add tags with special characters

This example adds the tag **[Group]=test** to an instance. The square brackets ([and]) are special characters, which must be escaped.

If you are using Linux or OS X, to escape the special characters, enclose the element with the special character with double quotes ("), and then enclose the entire key and value structure with single quotes (').

```
aws ec2 create-tags \
--resources i-1234567890abcdef0 \
--tags 'Key=[Group]',Value=test'
```

If you are using Windows, to escape the special characters, enclose the element that has special characters with double quotes ("), and then precede each double quote character with a backslash (\) as follows:

```
aws ec2 create-tags ^
--resources i-1234567890abcdef0 ^
--tags Key=\"[Group]\",Value=test
```

If you are using Windows PowerShell, to escape the special characters, enclose the value that has special characters with double quotes ("), precede each double quote character with a backslash (\), and then enclose the entire key and value structure with single quotes (') as follows:

```
aws ec2 create-tags ` 
--resources i-1234567890abcdef0 ` 
--tags 'Key=\\"[Group]\\",Value=test'
```

Describe tagged resources

The following examples show you how to use filters with the [describe-instances](#) to view instances with specific tags. All EC2 describe commands use this syntax to filter by tag across a single resource type. Alternatively, you can use the [describe-tags](#) command to filter by tag across EC2 resource types.

Example Example: Describe instances with the specified tag key

The following command describes the instances with a **Stack** tag, regardless of the value of the tag.

```
aws ec2 describe-instances \  
--filters Name=tag-key,Values=Stack
```

Example Example: Describe instances with the specified tag

The following command describes the instances with the tag **Stack=production**.

```
aws ec2 describe-instances \  
--filters Name=tag:Stack,Values=production
```

Example Example: Describe instances with the specified tag value

The following command describes the instances with a tag with the value **production**, regardless of the tag key.

```
aws ec2 describe-instances \  
--filters Name=tag-value,Values=production
```

Example Example: Describe all EC2 resources with the specified tag

The following command describes all EC2 resources with the tag **Stack=Test**.

```
aws ec2 describe-tags \  
--filters Name=key,Values=Stack Name=value,Values=Test
```

Work with instance tags in instance metadata

You can access an instance's tags from the instance metadata. By accessing tags from the instance metadata, you no longer need to use the `DescribeInstances` or `DescribeTags` API calls to retrieve tag information, which reduces your API transactions per second, and lets your tag retrievals scale with the number of instances that you control. Furthermore, local processes that are running on an instance can view the instance's tag information directly from the instance metadata.

By default, tags are not available from the instance metadata; you must explicitly allow access. You can allow access at instance launch, or after launch on a running or stopped instance. You can also allow access to tags by specifying this in a launch template. Instances that are launched by using the template allow access to tags in the instance metadata.

If you add or remove an instance tag, the instance metadata is updated while the instance is running, without needing to stop and then start the instance.

Topics

- [Allow access to tags in instance metadata \(p. 2097\)](#)
- [Turn off access to tags in instance metadata \(p. 2098\)](#)
- [View if access to tags in instance metadata is allowed \(p. 2098\)](#)
- [Retrieve tags from instance metadata \(p. 2099\)](#)

Allow access to tags in instance metadata

By default, there is no access to instance tags in the instance metadata. For each instance, you must explicitly allow access by using one of the following methods.

To allow access to tags in instance metadata using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and then choose **Actions**, **Instance settings**, **Allow tags in instance metadata**.
4. To allow access to tags in instance metadata, select the **Allow** check box.
5. Choose **Save**.

To allow access to tags in instance metadata at launch using the AWS CLI

Use the [run-instances](#) command and set `InstanceMetadataTags` to enabled.

```
aws ec2 run-instances \
--image-id ami-0abcdef1234567890 \
--instance-type c3.large \
...
--metadata-options "InstanceMetadataTags=enabled"
```

To allow access to tags in instance metadata on a running or stopped instance using the AWS CLI

Use the [modify-instance-metadata-options](#) command and set `--instance-metadata-tags` to enabled.

```
aws ec2 modify-instance-metadata-options \
--instance-id i-123456789example \
--instance-metadata-tags enabled
```

Turn off access to tags in instance metadata

To turn off access to instance tags in the instance metadata, use one of the following methods. You don't need to turn off access to instance tags on instance metadata at launch because it's turned off by default.

To turn off access to tags in instance metadata using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and then choose **Actions**, **Instance settings**, **Allow tags in instance metadata**.
4. To turn off access to tags in instance metadata, clear the **Allow** check box.
5. Choose **Save**.

To turn off access to tags in instance metadata using the AWS CLI

Use the [modify-instance-metadata-options](#) command and set `--instance-metadata-tags` to disabled.

```
aws ec2 modify-instance-metadata-options \
--instance-id i-123456789example \
--instance-metadata-tags disabled
```

View if access to tags in instance metadata is allowed

For each instance, you can use the Amazon EC2 console or AWS CLI to view whether access to instance tags from the instance metadata is allowed.

To view if access to tags in instance metadata is allowed using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, and then select an instance.
3. On the **Details** tab, check the **Allow tags in instance metadata** field. If the value is **Enabled**, tags in instance metadata is allowed. If the value is **Disabled**, tags in instance metadata is not allowed.

To view if access to tags in instance metadata is allowed using the AWS CLI

Use the [describe-instances](#) command and specify the instance ID.

```
aws ec2 describe-instances \
--instance-ids i-1234567890abcdef0
```

The following example output is truncated for space. The "InstanceMetadataTags" parameter indicates whether tags in instance metadata is allowed. If the value is enabled, tags in instance metadata is allowed. If the value is disabled, tags in instance metadata is not allowed.

```
{
    "Reservations": [
        {
            "Groups": [],
            "Instances": [
                {
                    "AmiLaunchIndex": 0,
                    "ImageId": "ami-0abcdef1234567890",
                    "InstanceId": "i-1234567890abcdef0",
                    ...
                    "MetadataOptions": {
                        "State": "applied",
                        "HttpTokens": "optional",
                        "HttpPutResponseHopLimit": 1,
                        "HttpEndpoint": "enabled",
                        "HttpProtocolIpv6": "disabled",
                        "InstanceMetadataTags": "enabled"
                    },
                    ...
                }
            ]
        }
    ]
}
```

Retrieve tags from instance metadata

If instance tags are allowed in the instance metadata, the tags/instance category is accessible from the instance metadata. For examples on how to retrieve tags from the instance metadata, see [Get the instance tags for an instance \(p. 883\)](#).

Add tags to a resource using CloudFormation

With Amazon EC2 resource types, you specify tags using either a Tags or TagSpecifications property.

The following examples add the tag **Stack=Production** to [AWS::EC2::Instance](#) using its Tags property.

Example Example: Tags in YAML

```
Tags:
  - Key: "Stack"
```

```
Value: "Production"
```

Example Example: Tags in JSON

```
"Tags": [  
  {  
    "Key": "Stack",  
    "Value": "Production"  
  }  
]
```

The following examples add the tag **Stack=Production** to [AWS::EC2::LaunchTemplate](#) [LaunchTemplateData](#) using its TagSpecifications property.

Example Example: TagSpecifications in YAML

```
TagSpecifications:  
  - ResourceType: "instance"  
    Tags:  
      - Key: "Stack"  
        Value: "Production"
```

Example Example: TagSpecifications in JSON

```
"TagSpecifications": [  
  {  
    "ResourceType": "instance",  
    "Tags": [  
      {  
        "Key": "Stack",  
        "Value": "Production"  
      }  
    ]  
  }  
]
```

Amazon EC2 service quotas

Amazon EC2 provides different resources that you can use. These resources include images, instances, volumes, and snapshots. When you create your AWS account, we set default *quotas* (also referred to as *limits*) on these resources on a per-Region basis. For example, there is a maximum number of instances that you can launch in a Region. So if you were to launch an instance in the US West (Oregon) Region, for example, the request must not cause your usage to exceed your maximum number of instances in that Region.

The Service Quotas console is a central location where you can view and manage your quotas for AWS services, and request a quota increase for many of the resources that you use. Use the quota information that we provide to manage your AWS infrastructure. Plan to request any quota increases in advance of the time that you'll need them.

For more information, see [Amazon EC2 endpoints and quotas](#) in the *Amazon Web Services General Reference*. For information about Amazon EBS quotas, see [Amazon EBS quotas \(p. 1996\)](#).

View your current quotas

You can view your quotas for each Region using the Service Quotas console.

To view your current quotas using the Service Quotas console

1. Open the Service Quotas console at <https://console.aws.amazon.com/servicequotas/home/services/ec2/quotas/>.
2. From the navigation bar (at the top of the screen), select a Region.

The screenshot shows a list of AWS Regions in the Service Quotas console. The regions listed are:

Region Name	AWS Region
US East (N. Virginia)	us-east-1
US East (Ohio)	us-east-2
US West (N. California)	us-west-1
US West (Oregon)	us-west-2
Africa (Cape Town)	af-south-1
Asia Pacific (Hong Kong)	ap-east-1
Asia Pacific (Jakarta)	ap-southeast-3

3. Use the filter field to filter the list by resource name. For example, enter **On-Demand** to locate the quotas for On-Demand Instances.
4. To view more information, choose the quota name to open the details page for the quota.

Request an increase

You can request a quota increase for each Region.

To request an increase using the Service Quotas console

1. Open the Service Quotas console at <https://console.aws.amazon.com/servicequotas/home/services/ec2/quotas/>.
2. From the navigation bar (at the top of the screen), select a Region.
3. Use the filter field to filter the list by resource name. For example, enter **On-Demand** to locate the quotas for On-Demand Instances.
4. If the quota is adjustable, choose the quota and then choose **Request quota increase**.
5. For **Change quota value**, enter the new quota value.
6. Choose **Request**.
7. To view any pending or recently resolved requests in the console, choose **Dashboard** from the navigation pane. For pending requests, choose the status of the request to open the request receipt. The initial status of a request is **Pending**. After the status changes to **Quota requested**, you'll see the case number with AWS Support. Choose the case number to open the ticket for your request.

For more information, including how to use the AWS CLI or SDKs to request a quota increase, see [Requesting a quota increase](#) in the *Service Quotas User Guide*.

Restriction on email sent using port 25

On all instances, Amazon EC2 restricts outbound traffic to public IP addresses over port 25 by default. You can request that this restriction be removed. For more information, see [How do I remove the restriction on port 25 from my Amazon EC2 instance or AWS Lambda function?](#) in the AWS Knowledge Center.

Note

This restriction does not apply to outbound traffic sent over port 25 to:

- IP addresses in the primary CIDR block of the VPC in which the originating network interface exists.
- IP addresses in the CIDRs defined in [RFC 1918](#), [RFC 6598](#), and [RFC 4193](#).

Amazon EC2 usage reports

AWS provides a free reporting tool called AWS Cost Explorer that enables you to analyze the cost and usage of your EC2 instances and the usage of your Reserved Instances. You can view data up to the last 12 months, and forecast how much you are likely to spend for the next three months. You can use Cost Explorer to see patterns in how much you spend on AWS resources over time, identify areas that need further inquiry, and see trends that you can use to understand your costs. You also can specify time ranges for the data, and view time data by day or by month.

Here's an example of some of the questions that you can answer when using Cost Explorer:

- How much am I spending on instances of each instance type?
- How many instance hours are being used by a particular department?
- How is my instance usage distributed across Availability Zones?
- How is my instance usage distributed across AWS accounts?
- How well am I using my Reserved Instances?
- Are my Reserved Instances helping me save money?

For more information about working with reports in Cost Explorer, including saving reports, see [Analyzing your costs with AWS Cost Explorer](#) in the *AWS Cost Management User Guide*.

Troubleshoot EC2 Windows instances

The following procedures and tips can help you troubleshoot problems with your Amazon EC2 Windows instances.

Contents

- [Common issues with Windows instances \(p. 2103\)](#)
- [Common messages troubleshooting Windows instances \(p. 2108\)](#)
- [Troubleshoot instance launch issues \(p. 2114\)](#)
- [Troubleshoot connecting to your Windows instance \(p. 2119\)](#)
- [Troubleshoot an unreachable instance \(p. 2126\)](#)

- [Troubleshoot the Elastic Network Adapter \(ENA\) Windows driver \(p. 2150\)](#)
- [Use EC2Rescue for Windows Server \(p. 2160\)](#)
- [EC2 Serial Console for Windows instances \(p. 2172\)](#)
- [Send a diagnostic interrupt \(for advanced users\) \(p. 2189\)](#)

To get additional information for troubleshooting problems with your instance, use [Use EC2Rescue for Windows Server \(p. 2160\)](#). For information about troubleshooting issues with PV drivers, see [Troubleshoot PV drivers \(p. 791\)](#).

Common issues with Windows instances

The following are troubleshooting tips to help you solve common issues with EC2 Windows Server instances.

Issues

- [EBS volumes don't initialize on Windows Server 2016 and 2019 \(p. 2103\)](#)
- [Boot an EC2 Windows instance into Directory Services Restore Mode \(DSRM\) \(p. 2104\)](#)
- [Instance loses network connectivity or scheduled tasks don't run when expected \(p. 2106\)](#)
- [Unable to get console output \(p. 2107\)](#)
- [Windows Server 2012 R2 not available on the network \(p. 2107\)](#)
- [Disk signature collision \(p. 2107\)](#)

EBS volumes don't initialize on Windows Server 2016 and 2019

Instances created from Amazon Machine Images (AMIs) for Windows Server 2016 and 2019 use the EC2Launch v1 agent for a variety of startup tasks, including initializing EBS volumes. By default,

EC2Launch v1 doesn't initialize secondary volumes. However, you can configure EC2Launch v1 to initialize these disks automatically, as follows.

Map drive letters to volumes

1. Connect to the instance to configure and open the C:\ProgramData\Amazon\EC2-Windows\Launch\Config\DriveLetterMappingConfig.json file in a text editor.
2. Specify the volume settings as follows:

```
{  
  "driveLetterMapping": [  
    {  
      "volumeName": "sample volume",  
      "driveLetter": "H"  
    }]  
}
```

3. Save your changes and close the file.
4. Open Windows PowerShell and use the following command to run the EC2Launch v1 script that initializes the disks:

```
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeDisks.ps1
```

To initialize the disks each time the instance boots, add the -Schedule flag as follows:

```
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeDisks.ps1 -Schedule
```

The EC2Launch v1 agent can run instance initialization scripts such as `initializeDisks.ps1` in parallel with the `InitializeInstance.ps1` script. If the `InitializeInstance.ps1` script reboots the instance, it might interrupt other scheduled tasks that run at instance startup. To avoid any potential conflicts, we recommend that you add logic to your `initializeDisks.ps1` script to ensure that instance initialization has finished first.

Note

If the EC2Launch script does not initialize the volumes, ensure that the volumes are online. If the volumes are offline, run the following command to bring all disks online.

```
PS C:\> Get-Disk | Where-Object IsOffline -Eq $True | Set-Disk -IsOffline  
$False
```

Boot an EC2 Windows instance into Directory Services Restore Mode (DSRM)

If an instance running Microsoft Active Directory experiences a system failure or other critical issues you can troubleshoot the instance by booting into a special version of Safe Mode called *Directory Services Restore Mode* (DSRM). In DSRM you can repair or recover Active Directory.

Driver support for DSRM

How you enable DSRM and boot into the instance depends on the drivers the instance is running. In the EC2 console you can view driver version details for an instance from the System Log. The following table shows which drivers are supported for DSRM.

Driver Versions	DSRM Supported?	Next Steps
Citrix PV 5.9	No	Restore the instance from a backup. You cannot enable DSRM.
AWS PV 7.2.0	No	Though DSRM is not supported for this driver, you can still detach the root volume from the instance, take a snapshot of the volume or create an AMI from it, and attach it to another instance in the same Availability Zone as a secondary volume. You can then enable DSRM (as described in this section).
AWS PV 7.2.2 and later	Yes	Detach the root volume, attach it to another instance, and enable DSRM (as described in this section).
Enhanced Networking	Yes	Detach the root volume, attach it to another instance, and enable DSRM (as described in this section).

For information about how to enable Enhanced Networking, see [Enabling Enhanced Networking on Windows Instances in a VPC](#). For more information about upgrading AWS PV drivers, see [Upgrade PV drivers on Windows instances \(p. 786\)](#).

Configure an instance to boot into DSRM

EC2 Windows instances do not have network connectivity before the operating system is running. For this reason, you cannot press the F8 button on your keyboard to select a boot option. You must use one of the following procedures to boot an EC2 Windows Server instance into DSRM.

If you suspect that Active Directory has been corrupted and the instance is still running, you can configure the instance to boot into DSRM using either the System Configuration dialog box or the command prompt.

To boot an online instance into DSRM using the System Configuration dialog box

1. In the **Run** dialog box, type msconfig and press Enter.
2. Choose the **Boot** tab.
3. Under **Boot options** choose **Safe boot**.
4. Choose **Active Directory repair** and then choose **OK**. The system prompts you to reboot the server.

To boot an online instance into DSRM using the command line

From a Command Prompt window, run the following command:

```
bcdeedit /set safeboot dsrepair
```

If an instance is offline and unreachable, you must detach the root volume and attach it to another instance to enable DSRM mode.

To boot an offline instance into DSRM

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Locate and select the affected instance. Choose **Instance state, Stop instance**.

-
4. Choose **Launch instances** and create a temporary instance in the same Availability Zone as the affected instance. Choose an instance type that uses a different version of Windows. For example, if your instance is Windows Server 2008, then choose a Windows Server 2008 R2 instance.

Important

If you do not create the instance in the same Availability Zone as the affected instance you will not be able to attach the root volume of the affected instance to the new instance.

5. In the navigation pane, choose **Volumes**.
6. Locate the root volume of the affected instance. [Detach](#) the volume and [attach](#) it to the temporary instance you created earlier. Attach it with the default device name (xvdf).
7. Use Remote Desktop to connect to the temporary instance, and then use the Disk Management utility to [make the volume available for use](#).
8. Open a command prompt and run the following command. Replace *D* with the actual drive letter of the secondary volume you just attached:

```
bcdedit /store D:\Boot\BCD /set {default} safeboot dsrepair
```

9. In the Disk Management Utility, choose the drive you attached earlier, open the context (right-click) menu, and choose **Offline**.
10. In the EC2 console, detach the affected volume from the temporary instance and reattach it to your original instance with the device name /dev/sda1. You must specify this device name to designate the volume as a root volume.
11. [Start](#) the instance.
12. After the instance passes the health checks in the EC2 console, connect to the instance using Remote Desktop and verify that it boots into DSRM mode.
13. (Optional) Delete or stop the temporary instance you created in this procedure.

Instance loses network connectivity or scheduled tasks don't run when expected

If you restart your instance and it loses network connectivity, it's possible that the instance has the wrong time.

By default, Windows instances use Coordinated Universal Time (UTC). If you set the time for your instance to a different time zone and then restart it, the time becomes offset and the instance temporarily loses its IP address. The instance regains network connectivity eventually, but this can take several hours. The amount of time that it takes for the instance to regain network connectivity depends on the difference between UTC and the other time zone.

This same time issue can also result in scheduled tasks not running when you expect them to. In this case, the scheduled tasks do not run when expected because the instance has the incorrect time.

To use a time zone other than UTC persistently, you must set the **RealTimelsUniversal** registry key. Without this key, an instance uses UTC after you restart it.

To resolve time issues that cause a loss of network connectivity

1. Ensure that you are running the recommended PV drivers. For more information, see [Upgrade PV drivers on Windows instances \(p. 786\)](#).
2. Verify that the following registry key exists and is set to 1: **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\TimeZoneInformation\RealTimelsUniversal**

Unable to get console output

For Windows instances, the instance console displays the output from tasks performed during the Windows boot process. If Windows boots successfully, the last message logged is Windows is Ready to use. Note that you can also display event log messages in the console, but this feature is not enabled by default. For more information, see [EC2 service properties \(p. 757\)](#).

To get the console output for your instance using the Amazon EC2 console, select the instance, and then choose **Actions, Monitor and troubleshoot, Get system log**. To get the console output using the command line, use one of the following commands: [get-console-output](#) (AWS CLI) or [Get-EC2ConsoleOutput](#) (AWS Tools for Windows PowerShell).

For instances running Windows Server 2012 R2 and earlier, if the console output is empty, it could indicate an issue with the EC2Config service, such as a misconfigured configuration file, or that Windows failed to boot properly. To fix the issue, download and install the latest version of EC2Config. For more information, see [Install the latest version of EC2Config \(p. 755\)](#).

Windows Server 2012 R2 not available on the network

For information about troubleshooting a Windows Server 2012 R2 instance that is not available on the network, see [Windows Server 2012 R2 loses network and storage connectivity after an instance reboot \(p. 791\)](#).

Disk signature collision

You can check for and resolve disk signature collisions using [EC2Rescue for Windows Server \(p. 2160\)](#). Or, you can manually resolve disk signature issues by performing the following steps.

Warning

The following procedure describes how to edit the Windows Registry using Registry Editor. If you are not familiar with the Windows Registry or how to safely make changes using Registry Editor, see [Configure the Registry](#).

1. Open a command prompt, type `regedit.exe`, and press Enter.
2. In the **Registry Editor**, choose **HKEY_LOCAL_MACHINE** from the context menu (right-click), and then choose **Find**.
3. Type **Windows Boot Manager** and then choose **Find Next**.
4. Choose the key named `11000001`. This key is a sibling of the key you found in the previous step.
5. In the right pane, choose **Element** and then choose **Modify** from the context menu (right-click).
6. Locate the four-byte disk signature at offset `0x38` in the data. This is the Boot Configuration Database signature (BCD). Reverse the bytes to create the disk signature, and write it down. For example, the disk signature represented by the following data is `E9EB3AA5`:

```
...
0030  00 00 00 00 01 00 00 00
0038  A5 3A EB E9 00 00 00 00
0040  00 00 00 00 00 00 00 00
...
```

7. In a Command Prompt window, run the following command to start Microsoft DiskPart.

```
diskpart
```

- Run the `select disk` DiskPart command and specify the disk number for the volume with the disk signature collision.

Tip

To check the disk number for the volume with the disk signature collision, use the **Disk Management** utility. Open a command prompt, type `compmgmt.msc` and press **Enter**. In the left-hand navigation panel, double-click **Disk Management**. In the **Disk Management** utility, check the disk number for the offline volume with the disk signature collision.

```
DISKPART> select disk 1
Disk 1 is now the selected disk.
```

- Run the following DiskPart command to get the disk signature.

```
DISKPART> uniqueid disk
Disk ID: 0C764FA8
```

- If the disk signature shown in the previous step doesn't match the disk signature that you wrote down earlier, use the following DiskPart command to change the disk signature so that it matches:

```
DISKPART> uniqueid disk id=E9EB3AA5
```

Common messages troubleshooting Windows instances

This section includes tips to help you troubleshoot issues based on common messages.

Topics

- ["Password is not available" \(p. 2108\)](#)
- ["Password not available yet" \(p. 2109\)](#)
- ["Cannot retrieve Windows password" \(p. 2109\)](#)
- ["Waiting for the metadata service" \(p. 2109\)](#)
- ["Unable to activate Windows" \(p. 2112\)](#)
- ["Windows is not genuine \(0x80070005\)" \(p. 2113\)](#)
- ["No Terminal Server License Servers available to provide a license" \(p. 2114\)](#)
- ["Some settings are managed by your organization" \(p. 2114\)](#)

"Password is not available"

To connect to a Windows instance using Remote Desktop, you must specify an account and password. The accounts and passwords provided are based on the AMI that you used to launch the instance. You can either retrieve the auto-generated password for the Administrator account, or use the account and password that were in use in the original instance from which the AMI was created.

You can generate a password for the Administrator account for instances launched using a custom Windows AMI. To generate the password, you will need to configure some settings in the operating system before the AMI is created. For more information, see [Create a custom Windows AMI \(p. 151\)](#).

If your Windows instance isn't configured to generate a random password, you'll receive the following message when you retrieve the auto-generated password using the console:

```
Password is not available.
```

The instance was launched from a custom AMI, or the default password has changed. A password cannot be retrieved for this instance. If you have forgotten your password, you can reset it using the Amazon EC2 configuration service. For more information, see [Passwords for a Windows Server instance](#).

Check the console output for the instance to see whether the AMI that you used to launch it was created with password generation disabled. If password generation is disabled, the console output contains the following:

```
Ec2SetPassword: Disabled
```

If password generation is disabled and you don't remember the password for the original instance, you can reset the password for this instance. For more information, see [Reset a lost or expired Windows administrator password \(p. 2134\)](#).

"Password not available yet"

To connect to a Windows instance using Remote Desktop, you must specify an account and password. The accounts and passwords provided are based on the AMI that you used to launch the instance. You can either retrieve the auto-generated password for the Administrator account, or use the account and password that were in use in the original instance from which the AMI was created.

Your password should be available within a few minutes. If the password isn't available, you'll receive the following message when you retrieve the auto-generated password using the console:

```
Password not available yet.  
Please wait at least 4 minutes after launching an instance before trying to retrieve the auto-generated password.
```

If it's been longer than four minutes and you still can't get the password, it's possible that the launch agent for your instance is not configured to generate a password. Verify by checking whether the console output is empty. For more information, see [Unable to get console output \(p. 2107\)](#).

Also verify that the AWS Identity and Access Management (IAM) account being used to access the Management Portal has the ec2:GetPasswordData action allowed. For more information about IAM permissions, see [What is IAM?](#).

"Cannot retrieve Windows password"

To retrieve the auto-generated password for the Administrator account, you must use the private key for the key pair that you specified when you launched the instance. If you didn't specify a key pair when you launched the instance, you'll receive the following message.

```
Cannot retrieve Windows password
```

You can terminate this instance and launch a new instance using the same AMI, making sure to specify a key pair.

"Waiting for the metadata service"

A Windows instance must obtain information from its instance metadata before it can activate itself. By default, the `WaitForMetaDataAvailable` setting ensures that the EC2Config service waits for the instance metadata to be accessible before continuing with the boot process. For more information, see [Instance metadata and user data \(p. 862\)](#).

If the instance is failing the instance reachability test, try the following to resolve this issue.

- Check the CIDR block for your VPC. A Windows instance cannot boot correctly if it's launched into a VPC that has an IP address range from 224.0.0.0 to 255.255.255.255 (Class D and Class E IP address ranges). These IP address ranges are reserved, and should not be assigned to host devices. We recommend that you create a VPC with a CIDR block from the private (non-publicly routable) IP address ranges as specified in [RFC 1918](#).
- It's possible that the system has been configured with a static IP address. Try [creating a network interface \(p. 1301\)](#) and [attaching it to the instance \(p. 1304\)](#).
- **To enable DHCP on a Windows instance that you can't connect to**
 1. Stop the affected instance and detach its root volume.
 2. Launch a temporary instance in the same Availability Zone as the affected instance.

Warning

If your temporary instance is based on the same AMI that the original instance is based on, you must complete additional steps or you won't be able to boot the original instance after you restore its root volume because of a disk signature collision. Alternatively, select a different AMI for the temporary instance. For example, if the original instance uses the AWS Windows AMI for Windows Server 2008 R2, launch the temporary instance using the AWS Windows AMI for Windows Server 2012.

3. Attach the root volume from the affected instance to this temporary instance. Connect to the temporary instance, open the **Disk Management** utility, and bring the drive online.
4. From the temporary instance, open **Regedit** and select **HKEY_LOCAL_MACHINE**. From the **File** menu, choose **Load Hive**. Select the drive, open the file `Windows\System32\config\SYSTEM`, and specify a key name when prompted (you can use any name).
5. Select the key that you just loaded and navigate to `ControlSet001\Services\Tcpip\Parameters\Interfaces`. Each network interface is listed by a GUID. Select the correct network interface. If DHCP is disabled and a static IP address assigned, `EnableDHCP` is set to 0. To enable DHCP, set `EnableDHCP` to 1, and delete the following keys if they exist: `NameServer`, `SubnetMask`, `IPAddress`, and `DefaultGateway`. Select the key again, and from the **File** menu, choose **Unload Hive**.

Note

If you have multiple network interfaces, you'll need to identify the correct interface to enable DHCP. To identify the correct network interface, review the following key values `NameServer`, `SubnetMask`, `IPAddress`, and `DefaultGateway`. These values display the static configuration of the previous instance.

6. (Optional) If DHCP is already enabled, it's possible that you don't have a route to the metadata service. Updating EC2Config can resolve this issue.
 - a. [Download](#) and install the latest version of the EC2Config service. For more information about installing this service, see [Install the latest version of EC2Config \(p. 755\)](#).
 - b. Extract the files from the .zip file to the Temp directory on the drive you attached.
 - c. Open **Regedit** and select **HKEY_LOCAL_MACHINE**. From the **File** menu, choose **Load Hive**. Select the drive, open the file `Windows\System32\config\SOFTWARE`, and specify a key name when prompted (you can use any name).
 - d. Select the key that you just loaded and navigate to `Microsoft\Windows\CurrentVersion`. Select the `RunOnce` key. (If this key doesn't exist, right-click `CurrentVersion`, point to **New**, select **Key**, and name the key `RunOnce`.) Right-click, point to **New**, and select **String Value**. Enter `Ec2Install` as the name and `C:\Temp\Ec2Install.exe -q` as the data.
 - e. Select the key again, and from the **File** menu, choose **Unload Hive**.

7. (Optional) If your temporary instance is based on the same AMI that the original instance is based on, you must complete the following steps or you won't be able to boot the original instance after you restore its root volume because of a disk signature collision.

Warning

The following procedure describes how to edit the Windows Registry using Registry Editor. If you are not familiar with the Windows Registry or how to safely make changes using Registry Editor, see [Configure the Registry](#).

- a. Open a command prompt, type **regedit.exe**, and press Enter.
- b. In the **Registry Editor**, choose **HKEY_LOCAL_MACHINE** from the context menu (right-click), and then choose **Find**.
- c. Type **Windows Boot Manager** and then choose **Find Next**.
- d. Choose the key named **11000001**. This key is a sibling of the key you found in the previous step.
- e. In the right pane, choose Element and then choose **Modify** from the context menu (right-click).
- f. Locate the four-byte disk signature at offset **0x38** in the data. Reverse the bytes to create the disk signature, and write it down. For example, the disk signature represented by the following data is **E9EB3AA5**:

```
...
0030  00 00 00 00 01 00 00 00
0038  A5 3A EB E9 00 00 00 00
0040  00 00 00 00 00 00 00 00
...
...
```

- g. In a Command Prompt window, run the following command to start Microsoft DiskPart.

```
diskpart
```

- h. Run the following DiskPart command to select the volume. (You can verify that the disk number is 1 using the **Disk Management** utility.)

```
DISKPART> select disk 1
Disk 1 is now the selected disk.
```

- i. Run the following DiskPart command to get the disk signature.

```
DISKPART> uniqueid disk
Disk ID: 0C764FA8
```

- j. If the disk signature shown in the previous step doesn't match the disk signature from BCD that you wrote down earlier, use the following DiskPart command to change the disk signature so that it matches:

```
DISKPART> uniqueid disk id=E9EB3AA5
```

8. Using the **Disk Management** utility, bring the drive offline.

Note

The drive is automatically offline if the temporary instance is running the same operating system as the affected instance, so you won't need to bring it offline manually.

9. Detach the volume from the temporary instance. You can terminate the temporary instance if you have no further use for it.

10. Restore the root volume of the affected instance by attaching the volume as /dev/sda1.
11. Start the affected instance.

If you are connected to the instance, open an Internet browser from the instance and enter the following URL for the metadata server:

```
http://169.254.169.254/latest/meta-data/
```

If you can't contact the metadata server, try the following to resolve the issue:

- [Download](#) and install the latest version of the EC2Config service. For more information about installing this service, see [Install the latest version of EC2Config \(p. 755\)](#).
- Check whether the Windows instance is running RedHat PV drivers. If so, update to Citrix PV drivers. For more information, see [Upgrade PV drivers on Windows instances \(p. 786\)](#).
- Verify that the firewall, IPSec, and proxy settings do not block outgoing traffic to the metadata service (169.254.169.254) or the AWS KMS servers (the addresses are specified in TargetKMServer elements in C:\Program Files\Amazon\Ec2ConfigService\Settings\ActivationSettings.xml).
- Verify that you have a route to the metadata service (169.254.169.254) using the following command.

```
route print
```

- Check for network issues that might affect the Availability Zone for your instance. Go to <http://status.aws.amazon.com/>.

"Unable to activate Windows"

Windows instances use Windows AWS KMS activation. You can receive this message: A problem occurred when Windows tried to activate. Error Code 0xC004F074, if your instance can't reach the AWS KMS server. Windows must be activated every 180 days. EC2Config attempts to contact the AWS KMS server before the activation period expires to ensure that Windows remains activated.

If you encounter a Windows activation issue, use the following procedure to resolve the issue.

For EC2Config (Windows Server 2012 R2 AMIs and earlier)

1. [Download](#) and install the latest version of the EC2Config service. For more information about installing this service, see [Install the latest version of EC2Config \(p. 755\)](#).
2. Log onto the instance and open the following file: C:\Program Files\Amazon\Ec2ConfigService\Settings\config.xml.
3. Locate the **Ec2WindowsActivate** plugin in the config.xml file. Change the state to **Enabled** and save your changes.
4. In the Windows Services snap-in, restart the EC2Config service or reboot the instance.

If this does not resolve the activation issue, follow these additional steps.

1. Set the AWS KMS target: **C:\> slmgr.vbs /skms 169.254.169.250:1688**
2. Activate Windows: **C:\> slmgr.vbs /ato**

For EC2Launch (Windows Server 2016 AMIs and later)

- From a PowerShell prompt with administrative rights, import the EC2Launch module:

```
PS C:\> Import-Module "C:\ProgramData\Amazon\EC2-Windows\Launch\Module\Ec2Launch.psd1"
```

- Call the Add-Routes function to see the list of new routes:

```
PS C:\> Add-Routes
```

- Call the Set-ActivationSettings function:

```
PS C:\> Set-Activationsettings
```

- Then, run the following script to activate Windows:

```
PS C:\> cscript "${env:SYSTEMROOT}\system32\s1mgr.vbs" /ato
```

For both EC2Config and EC2Launch, if you are still receiving an activation error, verify the following information.

- Verify that you have routes to the AWS KMS servers. Open C:\Program Files\Amazon\Ec2ConfigService\Settings\ActivationSettings.xml and locate the TargetKMSServer elements. Run the following command and check whether the addresses for these AWS KMS servers are listed.

```
route print
```

- Verify that the AWS KMS client key is set. Run the following command and check the output.

```
C:\Windows\System32\s1mgr.vbs /dlv
```

If the output contains Error: product key not found, the AWS KMS client key isn't set. If the AWS KMS client key isn't set, look up the client key as described in this Microsoft article: [AWS KMS Client Setup Keys](#), and then run the following command to set the AWS KMS client key.

```
C:\Windows\System32\s1mgr.vbs /ipk client_key
```

- Verify that the system has the correct time and time zone. If you are using Windows Server 2008 or later and a time zone other than UTC, add the following registry key and set it to 1 to ensure that the time is correct: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\TimeZoneInformation\RealTimeIsUniversal.
- If Windows Firewall is enabled, temporarily disable it using the following command.

```
netsh advfirewall set allprofiles state off
```

"Windows is not genuine (0x80070005)"

Windows instances use Windows AWS KMS activation. If an instance is unable to complete the activation process, it reports that the copy of Windows is not genuine.

Try the suggestions for ["Unable to activate Windows" \(p. 2112\)](#).

"No Terminal Server License Servers available to provide a license"

By default, Windows Server is licensed for two simultaneous users through Remote Desktop. If you need to provide more than two users with simultaneous access to your Windows instance through Remote Desktop, you can purchase a Remote Desktop Services client access license (CAL) and install the Remote Desktop Session Host and Remote Desktop Licensing Server roles.

Check for the following issues:

- You've exceeded the maximum number of concurrent RDP sessions.
- You've installed the Windows Remote Desktop Services role.
- Licensing has expired. If the licensing has expired, you can't connect to your Windows instance as a user. You can try the following:
 - Connect to the instance from the command line using an /admin parameter, for example:

```
mstsc /v:instance /admin
```

For more information, see the following Microsoft article: [Access Remote Desktop Via Command Line](#).

- Stop the instance, detach its Amazon EBS volumes, and attach them to another instance in the same Availability Zone to recover your data.

"Some settings are managed by your organization"

Instances launched from the latest Windows Server AMIs might show a Windows Update dialog message stating "Some settings are managed by your organization." This message appears as a result of changes in Windows Server and does not impact the behavior of Windows Update or your ability to manage update settings.

To remove the warning

1. Open gpedit.msc and navigate to **Computer Configuration, Administrative Templates, Windows Components, Windows updates**. Edit **Configure Automatic Update**, and set it to **enabled**.
2. In a command prompt, update group policy using **gpupdate /force**.
3. Close and reopen the Windows Update Settings. You will see the above message about your settings being managed by your organization, followed by "We'll automatically download updates, except on metered connections (where charges may apply). In that case, we'll automatically download those updates required to keep Windows running smoothly."
4. Return to gpedit.msc and set the group policy back to **not configured**. Run **gpupdate /force** again.
5. Close the command prompt and wait a few minutes.
6. Reopen the Windows Update Settings. You should not see the message "Some settings are managed by your organization."

Troubleshoot instance launch issues

The following issues prevent you from launching an instance.

Launch Issues

- [Invalid device name \(p. 2115\)](#)
- [Instance limit exceeded \(p. 2115\)](#)
- [Insufficient instance capacity \(p. 2116\)](#)
- [The requested configuration is currently not supported. Please check the documentation for supported configurations. \(p. 2116\)](#)
- [Instance terminates immediately \(p. 2117\)](#)
- [High CPU usage shortly after Windows starts \(p. 2118\)](#)
- [Insufficient permissions \(p. 2118\)](#)

Invalid device name

Description

You get the `Invalid device name device_name` error when you try to launch a new instance.

Cause

If you get this error when you try to launch an instance, the device name specified for one or more volumes in the request has an invalid device name. Possible causes include:

- The device name might be in use by the selected AMI.
- The device name might be reserved for root volumes.
- The device name might be used for another volume in the request.
- The device name might not be valid for the operating system.

Solution

To resolve the issue:

- Ensure that the device name is not used in the AMI that you selected. Run the following command to view the device names used by the AMI.

```
C:\> aws ec2 describe-images --image-id ami_id --query  
'Images[*].BlockDeviceMappings[] .DeviceName'
```

- Ensure that you are not using a device name that is reserved for root volumes. For more information, see [Available device names \(p. 2025\)](#).
- Ensure that each volume specified in your request has a unique device name.
- Ensure that the device names that you specified are in the correct format. For more information, see [Available device names \(p. 2025\)](#).

Instance limit exceeded

Description

You get the `InstanceLimitExceeded` error when you try to launch a new instance or restart a stopped instance.

Cause

If you get an `InstanceLimitExceeded` error when you try to launch a new instance or restart a stopped instance, you have reached the limit on the number of instances that you can launch in a Region. When you create your AWS account, we set default limits on the number of instances you can run on a per-Region basis.

Solution

You can request an instance limit increase on a per-region basis. For more information, see [Amazon EC2 service quotas \(p. 2100\)](#).

Insufficient instance capacity

Description

You get the `InsufficientInstanceCapacity` error when you try to launch a new instance or restart a stopped instance.

Cause

If you get this error when you try to launch an instance or restart a stopped instance, AWS does not currently have enough available On-Demand capacity to fulfill your request.

Solution

To resolve the issue, try the following:

- Wait a few minutes and then submit your request again; capacity can shift frequently.
- Submit a new request with a reduced number of instances. For example, if you're making a single request to launch 15 instances, try making 3 requests for 5 instances, or 15 requests for 1 instance instead.
- If you're launching an instance, submit a new request without specifying an Availability Zone.
- If you're launching an instance, submit a new request using a different instance type (which you can resize at a later stage). For more information, see [Change the instance type \(p. 344\)](#).
- If you are launching instances into a cluster placement group, you can get an insufficient capacity error. For more information, see [Working with placement groups \(p. 1356\)](#).

The requested configuration is currently not supported. Please check the documentation for supported configurations.

Description

You get the `Unsupported` error when you try to launch a new instance because the instance configuration is not supported.

Cause

The error message provides additional details. For example, an instance type or instance purchasing option might not be supported in the specified Region or Availability Zone.

Solution

Try a different instance configuration. To search for an instance type that meets your requirements, see [Find an Amazon EC2 instance type \(p. 340\)](#).

Instance terminates immediately

Description

Your instance goes from the pending state to the terminated state.

Cause

The following are a few reasons why an instance might immediately terminate:

- You've exceeded your EBS volume limits. For more information, see [Instance volume limits \(p. 2019\)](#).
- An EBS snapshot is corrupted.
- The root EBS volume is encrypted and you do not have permissions to access the KMS key for decryption.
- A snapshot specified in the block device mapping for the AMI is encrypted and you do not have permissions to access the KMS key for decryption or you do not have access to the KMS key to encrypt the restored volumes.
- The instance store-backed AMI that you used to launch the instance is missing a required part (an image.part.xx file).

For more information, get the termination reason using one of the following methods.

To get the termination reason using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, and select the instance.
3. On the first tab, find the reason next to **State transition reason**.

To get the termination reason using the AWS Command Line Interface

1. Use the [describe-instances](#) command and specify the instance ID.

```
aws ec2 describe-instances --instance-id instance_id
```

2. Review the JSON response returned by the command and note the values in the **StateReason** response element.

The following code block shows an example of a **StateReason** response element.

```
"StateReason": {  
    "Message": "Client.VolumeLimitExceeded: Volume limit exceeded",  
    "Code": "Server.InternalError"  
},
```

To get the termination reason using AWS CloudTrail

For more information, see [Viewing events with CloudTrail event history](#) in the *AWS CloudTrail User Guide*.

Solution

Depending on the termination reason, take one of the following actions:

- **Client.VolumeLimitExceeded: Volume limit exceeded** — Delete unused volumes. You can [submit a request](#) to increase your volume limit.
- **Client.InternalError: Client error on launch** — Ensure that you have the permissions required to access the AWS KMS keys used to decrypt and encrypt volumes. For more information, see [Using key policies in AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

High CPU usage shortly after Windows starts

If Windows Update is set to **Check for updates but let me choose whether to download and install them** (the default instance setting) this check can consume anywhere from 50 - 99% of the CPU on the instance. If this CPU consumption causes problems for your applications, you can manually change Windows Update settings in **Control Panel** or you can use the following script in the Amazon EC2 user data field:

```
reg add "HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\WindowsUpdate\Auto Update" /v AUOptions /t REG_DWORD /d 3 /f net stop wuauserv net start wuauserv
```

When you run this script, specify a value for /d. The default value is 3. Possible values include the following:

1. Never check for updates
2. Check for updates but let me choose whether to download and install them
3. Download updates but let me choose whether to install them
4. Install updates automatically

After you modify the user data for your instance, you can run it. For more information, see [View and update the instance user data \(p. 859\)](#) and [User data execution \(p. 856\)](#).

Insufficient permissions

Description

You get the "*errorMessage*": "You are not authorized to perform this operation." error when you try to launch a new instance, and the launch fails.

Cause

If you get this error when you try to launch an instance, you don't have the required IAM permissions to launch the instance.

Possible missing permissions include:

- `ec2:RunInstances`
- `iam:PassRole`

Other permissions might also be missing. For the list of permissions required to launch an instance, see the example IAM policies under [Example: Use the EC2 launch instance wizard \(p. 1640\)](#) and [Launch instances \(RunInstances\) \(p. 1614\)](#).

Solution

To resolve the issue:

- If you are making requests as an IAM user, verify that you have the following permissions:
 - `ec2:RunInstances` with a wildcard resource ("*")
 - `iam:PassRole` with the resource matching the role ARN (for example, `arn:aws:iam::999999999999:role/ExampleRoleName`)
- If you don't have the preceding permissions, [edit the IAM policy](#) associated with the IAM role or user to add the missing required permissions.

If your issue is not resolved and you continue receiving a launch failure error, you can decode the authorization failure message included in the error. The decoded message includes the permissions that are missing from the IAM policy. For more information, see [How can I decode an authorization failure message after receiving an "UnauthorizedOperation" error during an EC2 instance launch?](#)

Troubleshoot connecting to your Windows instance

The following are possible problems you might have and error messages you might see while trying to connect to your Windows instance.

Contents

- [Remote Desktop can't connect to the remote computer \(p. 2119\)](#)
- [Error using the macOS RDP client \(p. 2122\)](#)
- [RDP displays a black screen instead of the desktop \(p. 2122\)](#)
- [Unable to remotely log on to an instance with a user that is not an administrator \(p. 2122\)](#)
- [Troubleshooting Remote Desktop issues using AWS Systems Manager \(p. 2123\)](#)
- [Enable Remote Desktop on an EC2 Instance With Remote Registry \(p. 2125\)](#)
- [I've lost my private key. How can I connect to my Windows instance? \(p. 2126\)](#)

Remote Desktop can't connect to the remote computer

Try the following to resolve issues related to connecting to your instance:

- Verify that you're using the correct public DNS hostname. (In the Amazon EC2 console, select the instance and check **Public DNS (IPv4)** in the details pane.) If your instance is in a VPC and you do not see a public DNS name, you must enable DNS hostnames. For more information, see [DNS attributes for your VPC in the Amazon VPC User Guide](#).
- Verify that your instance has a public IPv4 address. If not, you can associate an Elastic IP address with your instance. For more information, see [Elastic IP addresses \(p. 1269\)](#).

- To connect to your instance using an IPv6 address, check that your local computer has an IPv6 address and is configured to use IPv6. If you launched an instance from a Windows Server 2008 SP2 AMI or earlier, your instance is not automatically configured to recognize an IPv6 address assigned to the instance. For more information, see [Configure IPv6 on your instances](#) in the *Amazon VPC User Guide*.
- Verify that your security group has a rule that allows RDP access. For more information, see [Create a security group \(p. 9\)](#).
- If you copied the password but get the error Your credentials did not work, try typing them manually when prompted. It's possible that you missed a character or got an extra white space character when you copied the password.
- Verify that the instance has passed status checks. For more information, see [Status checks for your instances \(p. 1153\)](#) and [Troubleshoot instances with failed status checks](#) (*Amazon EC2 User Guide for Linux Instances*).
- Verify that the route table for the subnet has a route that sends all traffic destined outside the VPC to the internet gateway for the VPC. For more information, see [Creating a custom route table](#) (Internet Gateways) in the *Amazon VPC User Guide*.
- Verify that Windows Firewall, or other firewall software, is not blocking RDP traffic to the instance. We recommend that you disable Windows Firewall and control access to your instance using security group rules. You can use [AWSSupport-TroubleshootRDP \(p. 2123\)](#) to [disable the Windows Firewall profiles using SSM Agent](#). To disable Windows Firewall on a Windows instance that is not configured for AWS Systems Manager, use [AWSSupport-ExecuteEC2Rescue \(p. 2125\)](#), or use the following manual steps:

Manual steps

1. Stop the affected instance and detach its root volume.
2. Launch a temporary instance in the same Availability Zone as the affected instance.

Warning

If your temporary instance is based on the same AMI that the original instance is based on, you must complete additional steps or you won't be able to boot the original instance after you restore its root volume because of a disk signature collision. Alternatively, select a different AMI for the temporary instance. For example, if the original instance uses the AWS Windows AMI for Windows Server 2008 R2, launch the temporary instance using the AWS Windows AMI for Windows Server 2012.

3. Attach the root volume from the affected instance to this temporary instance. Connect to the temporary instance, open the **Disk Management** utility, and bring the drive online.
4. Open **Regedit** and select **HKEY_LOCAL_MACHINE**. From the **File** menu, choose **Load Hive**. Select the drive, open the file `Windows\System32\config\SYSTEM`, and specify a key name when prompted (you can use any name).
5. Select the key you just loaded and navigate to `ControlSet001\Services\SharedAccess\Parameters\FirewallPolicy`. For each key with a name of the form `xxxxProfile`, select the key and change `EnableFirewall` from 1 to 0. Select the key again, and from the **File** menu, choose **Unload Hive**.
6. (Optional) If your temporary instance is based on the same AMI that the original instance is based on, you must complete the following steps or you won't be able to boot the original instance after you restore its root volume because of a disk signature collision.

Warning

The following procedure describes how to edit the Windows Registry using Registry Editor. If you are not familiar with the Windows Registry or how to safely make changes using Registry Editor, see [Configure the Registry](#).

- a. Open a command prompt, type `regedit.exe`, and press Enter.

- b. In the **Registry Editor**, choose **HKEY_LOCAL_MACHINE** from the context menu (right-click), and then choose **Find**.
- c. Type **Windows Boot Manager** and then choose **Find Next**.
- d. Choose the key named **11000001**. This key is a sibling of the key you found in the previous step.
- e. In the right pane, choose **Element** and then choose **Modify** from the context menu (right-click).
- f. Locate the four-byte disk signature at offset **0x38** in the data. Reverse the bytes to create the disk signature, and write it down. For example, the disk signature represented by the following data is **E9EB3AA5**:

```
...  
0030 00 00 00 00 01 00 00 00  
0038 A5 3A EB E9 00 00 00 00  
0040 00 00 00 00 00 00 00 00  
...
```

- g. In a Command Prompt window, run the following command to start Microsoft DiskPart.

```
diskpart
```

- h. Run the following DiskPart command to select the volume. (You can verify that the disk number is 1 using the **Disk Management** utility.)

```
DISKPART> select disk 1  
  
Disk 1 is now the selected disk.
```

- i. Run the following DiskPart command to get the disk signature.

```
DISKPART> uniqueid disk  
  
Disk ID: 0C764FA8
```

- j. If the disk signature shown in the previous step doesn't match the disk signature from BCD that you wrote down earlier, use the following DiskPart command to change the disk signature so that it matches:

```
DISKPART> uniqueid disk id=E9EB3AA5
```

7. Using the **Disk Management** utility, bring the drive offline.

Note

The drive is automatically offline if the temporary instance is running the same operating system as the affected instance, so you won't need to bring it offline manually.

8. Detach the volume from the temporary instance. You can terminate the temporary instance if you have no further use for it.
9. Restore the root volume of the affected instance by attaching it as /dev/sda1.
10. Start the instance.

- Verify that Network Level Authentication is disabled on instances that are not part of an Active Directory domain (use [AWS Support-TroubleshootRDP \(p. 2123\)](#) to [disable NLA](#)).
- Verify that the Remote Desktop Service (TermService) Startup Type is Automatic and the service is started (use [AWS Support-TroubleshootRDP \(p. 2123\)](#) to [enable and start the RDP service](#)).
- Verify that you are connecting to the correct Remote Desktop Protocol port, which by default is 3389 (use [AWS Support-TroubleshootRDP \(p. 2123\)](#) to [read the current RDP port](#) and [change it back to 3389](#)).

- Verify that Remote Desktop connections are allowed on your instance (use [AWS Support-TroubleshootRDP \(p. 2123\)](#) to [enable Remote Desktop connections](#)).
- Verify that the password has not expired. If the password has expired, you can reset it. For more information, see [Reset a lost or expired Windows administrator password \(p. 2134\)](#).
- If you attempt to connect using a user that you created on the instance and receive the error The user cannot connect to the server due to insufficient access privileges, verify that you granted the user the right to log on locally. For more information, see [Grant a Member the Right to Logon Locally](#).
- If you attempt more than the maximum allowed concurrent RDP sessions, your session is terminated with the message Your Remote Desktop Services session has ended. Another user connected to the remote computer, so your connection was lost. By default, you are allowed two concurrent RDP sessions to your instance.

Error using the macOS RDP client

If you are connecting to a Windows Server 2012 R2 instance using the Remote Desktop Connection client from the Microsoft website, you may get the following error:

Remote Desktop Connection cannot verify the identity of the computer that you want to connect to.

Download the Microsoft Remote Desktop app from the Mac App Store and use the app to connect to your instance.

RDP displays a black screen instead of the desktop

Try the following to resolve this issue:

- Check the console output for additional information. To get the console output for your instance using the Amazon EC2 console, select the instance, and then choose **Actions, Monitor and troubleshoot, Get system log**.
- Verify that you are running the latest version of your RDP client.
- Try the default settings for the RDP client. For more information, see [Remote Session Environment](#).
- If you are using Remote Desktop Connection, try starting it with the /admin option as follows.

```
mstsc /v:instance /admin
```

- If the server is running a full-screen application, it might have stopped responding. Use Ctrl+Shift+Esc to start Windows Task Manager, and then close the application.
- If the server is over-utilized, it might have stopped responding. To monitor the instance using the Amazon EC2 console, select the instance and then select the **Monitoring** tab. If you need to change the instance type to a larger size, see [Change the instance type \(p. 344\)](#).

Unable to remotely log on to an instance with a user that is not an administrator

If you are not able to remotely log on to a Windows instance with a user that is not an administrator account, ensure that you have granted the user the right to log on locally. See [Grant a user or group the right to log on locally to the domain controllers in the domain](#).

Troubleshooting Remote Desktop issues using AWS Systems Manager

You can use AWS Systems Manager to troubleshoot issues connecting to your Windows instance using RDP.

AWSSupport-TroubleshootRDP

The AWSSupport-TroubleshootRDP automation document allows the user to check or modify common settings on the target instance that can impact Remote Desktop Protocol (RDP) connections, such as the **RDP Port**, **Network Layer Authentication (NLA)**, and **Windows Firewall** profiles. By default, the document reads and outputs the values of these settings.

The AWSSupport-TroubleshootRDP automation document can be used with EC2 instances, on-premises instances, and virtual machines (VMs) that are enabled for use with AWS Systems Manager (managed instances). In addition, it can also be used with EC2 instances for Windows Server that are *not* enabled for use with Systems Manager. For information about enabling instances for use with AWS Systems Manager, see [Managed nodes](#) in the *AWS Systems Manager User Guide*.

To troubleshoot using the AWSSupport-TroubleshootRDP document

1. Log in to the [Systems Manager Console](#).
2. Verify that you are in the same Region as the impaired instance.
3. Choose **Documents** from the left navigation pane.
4. On the **Owned by Amazon** tab, enter AWSSupport-TroubleshootRDP in the search field. When the AWSSupport-TroubleshootRDP document appears, select it.
5. Choose **Execute automation**.
6. For **Execution Mode**, choose **Simple execution**.
7. For **Input parameters**, **InstanceId**, enable **Show interactive instance picker**.
8. Choose your Amazon EC2 instance.
9. Review the [examples \(p. 2123\)](#), then choose **Execute**.
10. To monitor the execution progress, for **Execution status**, wait for the status to change from **Pending** to **Success**. Expand **Outputs** to view the results. To view the output of individual steps, in **Executed Steps**, choose an item from **Step ID**.

AWSSupport-TroubleshootRDP examples

The following examples show you how to accomplish common troubleshooting tasks using AWSSupport-TroubleshootRDP. You can use either the example AWS CLI [start-automation-execution](#) command or the provided link to the AWS Management Console.

Example Example: Check the current RDP status

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --parameters "InstanceId=instance_id, Action=Custom" --region region_code
```

AWS Systems Manager console:

```
https://console.aws.amazon.com/systems-manager/automation/execute/AWSSupport-TroubleshootRDP?region=region#documentVersion=$LATEST
```

Example Example: Disable the Windows Firewall

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --parameters "InstanceId=instance_id, Action=Custom, Firewall=Disable" --region region_code
```

AWS Systems Manager console:

```
https://console.aws.amazon.com/systems-manager/automation/execute/AWSSupport-TroubleshootRDP?region=region_code#documentVersion=$LATEST&Firewall=Disable
```

Example Example: Disable Network Level Authentication

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --parameters "InstanceId=instance_id, Action=Custom, NLASettingAction=Disable" --region region_code
```

AWS Systems Manager console:

```
https://console.aws.amazon.com/systems-manager/automation/execute/AWSSupport-TroubleshootRDP?region=region_code#documentVersion
```

Example Example: Set RDP Service Startup Type to Automatic and start the RDP service

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --parameters "InstanceId=instance_id, Action=Custom, RDPServiceStartupType=Auto, RDPServiceAction=Start" --region region_code
```

AWS Systems Manager console:

```
https://console.aws.amazon.com/systems-manager/automation/execute/AWSSupport-TroubleshootRDP?region=region_code#documentVersion=$LATEST&RDPServiceStartupType=Auto&RDPServiceAction=Start
```

Example Example: Restore the default RDP Port (3389)

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP" --parameters "InstanceId=instance_id, Action=Custom, RDPPortAction=Modify" --region region_code
```

AWS Systems Manager console:

```
https://console.aws.amazon.com/systems-manager/automation/execute/AWSSupport-TroubleshootRDP?region=region_code#documentVersion=$LATEST&RDPPortAction=Modify
```

Example Example: Allow remote connections

AWS CLI:

```
aws ssm start-automation-execution --document-name "AWSSupport-TroubleshootRDP"  
--parameters "InstanceId=instance_id, Action=Custom, RemoteConnections=Enable" --  
region region_code
```

AWS Systems Manager console:

```
https://console.aws.amazon.com/systems-manager/automation/execute/AWSSupport-  
TroubleshootRDP?region=region_code#documentVersion=$LATEST&RemoteConnections=Enable
```

AWSSupport-ExecuteEC2Rescue

The AWSSupport-ExecuteEC2Rescue automation document uses [Use EC2Rescue for Windows Server \(p. 2160\)](#) to automatically troubleshoot and restore EC2 instance connectivity and RDP issues. For more information, see [Run the EC2Rescue tool on unreachable instances](#).

The AWSSupport-ExecuteEC2Rescue automation document requires a stop and restart of the instance. Systems Manager Automation stops the instance and creates an Amazon Machine Image (AMI). Data stored in instance store volumes is lost. The public IP address changes if you are not using an Elastic IP address. For more information, see [Run the EC2Rescue tool on unreachable instances](#) in the *AWS Systems Manager User Guide*.

To troubleshoot using the AWSSupport-ExecuteEC2Rescue document

1. Open the [Systems Manager console](#).
2. Verify that you are in the same Region as the impaired Amazon EC2 instance.
3. Open the [AWSSupport-ExecuteEC2Rescue](#) document.
4. In **Execution Mode**, choose **Simple execution**.
5. In the **Input parameters** section, for **UnreachableInstanceId**, enter the Amazon EC2 instance ID of the unreachable instance.
6. (Optional) For **LogDestination**, enter the Amazon Simple Storage Service (Amazon S3) bucket name if you want to collect operating system logs for troubleshooting your Amazon EC2 instance. Logs are automatically uploaded to the specified bucket.
7. Choose **Execute**.
8. To monitor the execution progress, in **Execution status**, wait for the status to change from **Pending** to **Success**. Expand **Outputs** to view the results. To view the output of individual steps, in **Executed Steps**, choose the **Step ID**.

Enable Remote Desktop on an EC2 Instance With Remote Registry

If your unreachable instance is not managed by AWS Systems Manager Session Manager, then you can use remote registry to enable Remote Desktop.

1. From the EC2 console, stop the unreachable instance.
2. Attach the root volume of the unreachable instance to another instance in the same Availability Zone.
3. On the instance to which you attached the root volume, open Disk Management. Open the Command Prompt and run the following command.

```
diskmgmt.msc
```

-
4. Right click on the root volume of the affected instance and choose **Online**.
 5. Open the Windows Registry Editor. In the Command Prompt, run the following command.

```
regedit
```

6. In the Registry Editor console tree, choose **HKEY_LOCAL_MACHINE**, then select **File>Load Hive**.
7. Select the drive of the attached volume, navigate to `\Windows\System32\config\`, select **SYSTEM**, and then choose **Open**.
8. For **Key Name**, enter a unique name for the hive and choose **OK**.
9. Back up the registry hive before making any changes to the registry.
 - a. In the Registry Editor console tree, select the hive that you loaded: `HKEY_LOCAL_MACHINE\your key name`.
 - b. Choose **File>Export**.
 - c. In the Export Registry File dialog box, choose the location to which you want to save the backup copy, and then type a name for the backup file in the **File name** field.
 - d. Choose **Save**.
10. In the Registry Editor console tree, navigate to `HKEY_LOCAL_MACHINE\your key name\ControlSet001\Control\Terminal Server`, and then, in the details pane, double-click on **fDenyTSConnections**.
11. In the **Edit DWORD** value box, enter `0` in the **Value data** field.
12. Choose **OK**.

Note

If the value in the **Value data** field is `1`, then the instance will deny remote desktop connections. A value of `0` allows remote desktop connections.

13. Close the Registry Editor and the Disk Management consoles.
14. From the EC2 console, detach the root volume from the instance to which you attached it and reattach it to the unreachable instance. When attaching the volume to the unreachable instance, enter `/dev/sda1` in the **device** field.
15. Restart the unreachable instance.

I've lost my private key. How can I connect to my Windows instance?

When you connect to a newly-launched Windows instance, you decrypt the password for the Administrator account using the private key for the key pair that you specified when you launched the instance.

If you lose the Administrator password and you no longer have the private key, you must reset the password or create a new instance. For more information, see [Reset a lost or expired Windows administrator password \(p. 2134\)](#). For steps to reset the password using an Systems Manager document, see [Reset passwords and SSH keys on EC2 instances](#) in the *AWS Systems Manager User Guide*.

Troubleshoot an unreachable instance

If you are unable to reach your Windows instance through SSH or RDP, you can capture a screenshot of your instance and view it as an image. This provides visibility into the status of the instance, and allows for quicker troubleshooting. You can also use [EC2 Rescue \(p. 2160\)](#) on instances running Windows Server 2008 or later to gather and analyze data from offline instances.

Topics

- [Get a screenshot of an unreachable instance \(p. 2127\)](#)
- [Common screenshots \(p. 2128\)](#)

For information about troubleshooting an unreachable Linux instance, see [Troubleshoot an unreachable instance](#).

Get a screenshot of an unreachable instance

You can get screenshots of an instance while it is running or after it has crashed. There is no data transfer cost for the screenshot. The image is generated in JPG format and is no larger than 100 kb.

This feature is supported on all instances, except in:

- Bare metal instances (instance types that end in .metal)
- Instance is using an NVIDIA GRID driver
- Instances powered by Arm-based Graviton processors

This feature is available in the following Regions:

- Asia Pacific (Hong Kong) Region
- Asia Pacific (Tokyo) Region
- Asia Pacific (Seoul) Region
- Asia Pacific (Singapore) Region
- Asia Pacific (Sydney) Region
- Asia Pacific (Mumbai) Region
- US East (N. Virginia) Region
- US East (Ohio) Region
- US West (Oregon) Region
- US West (N. California) Region
- Europe (Ireland) Region
- Europe (Frankfurt) Region
- Europe (Milan) Region
- Europe (London) Region
- Europe (Paris) Region
- Europe (Stockholm) Region
- Europe (Paris) Region
- South America (São Paulo) Region
- Canada (Central) Region
- Middle East (Bahrain) Region
- Africa (Cape Town) Region
- China (Beijing) Region
- China (Ningxia) Region

To get a screenshot of a running instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the left navigation pane, choose **Instances**.
3. Select the instance to capture.
4. Choose **Actions, Monitor and troubleshoot, Get instance screenshot**.
5. Choose **Download**, or right-click the image to download and save it.

To get a screenshot of a running instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [get-console-screenshot](#) (AWS CLI)
- [GetConsoleScreenshot](#) (Amazon EC2 Query API)

For API calls, the returned output is base64-encoded. For command line tools, the decoding is performed for you.

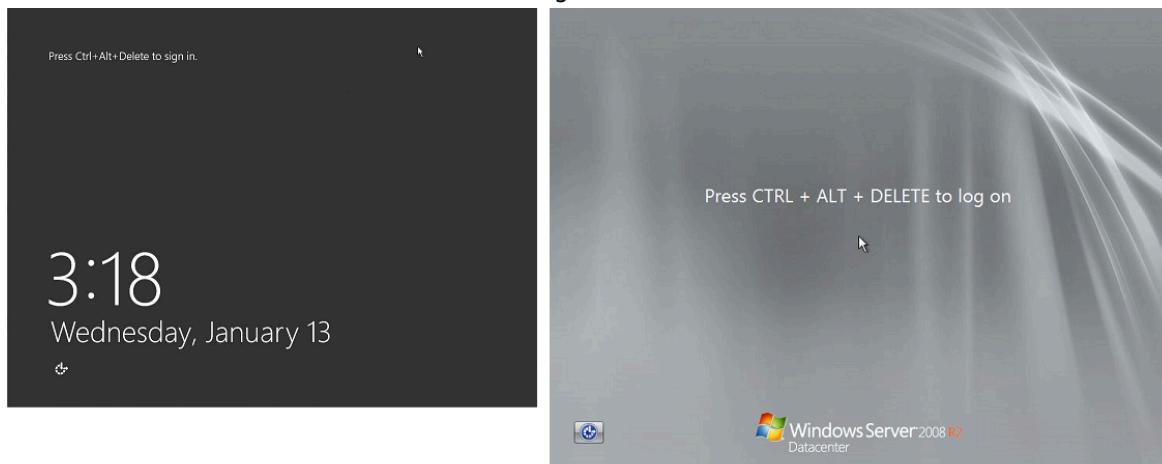

Common screenshots

You can use the following information to help you troubleshoot an unreachable instance based on screenshots returned by the service.

- [Log on screen \(Ctrl+Alt+Delete\) \(p. 2128\)](#)
- [Recovery console screen \(p. 2130\)](#)
- [Windows boot manager screen \(p. 2131\)](#)
- [Sysprep screen \(p. 2132\)](#)
- [Getting ready screen \(p. 2132\)](#)
- [Windows Update screen \(p. 2133\)](#)
- [Chkdsk \(p. 2134\)](#)

Log on screen (Ctrl+Alt+Delete)

Console Screenshot Service returned the following.

If an instance becomes unreachable during logon, there could be a problem with your network configuration or Windows Remote Desktop Services. An instance can also be unresponsive if a process is using large amounts of CPU.

Network configuration

Use the following information to verify that your AWS, Microsoft Windows, and local (or on-premises) network configurations aren't blocking access to the instance.

AWS network configuration

Configuration	Verify
Security group configuration	Verify that port 3389 is open for your security group. Verify you are connecting to the right public IP address. If the instance was not associated with an Elastic IP, the public IP changes after the instance stops/starts. For more information, see Remote Desktop can't connect to the remote computer (p. 2119) .
VPC configuration (Network ACLs)	Verify that the access control list (ACL) for your Amazon VPC is not blocking access. For information, see Network ACLs in the <i>Amazon VPC User Guide</i> .
VPN configuration	If you are connecting to your VPC using a virtual private network (VPN), verify VPN tunnel connectivity. For more information, see How do I troubleshoot VPN tunnel connectivity to an Amazon VPC?

Windows network configuration

Configuration	Verify
Windows Firewall	Verify that Windows Firewall isn't blocking connections to your instance. Disable Windows Firewall as described in bullet 7 of the remote desktop troubleshooting section, Remote Desktop can't connect to the remote computer (p. 2119) .
Advanced TCP/IP configuration (Use of static IP)	The instance may be unresponsive because you configured a static IP address. For a VPC, create a network interface (p. 1301) and attach it to the instance (p. 1304) .

Local or on-premises network configuration

Verify that a local network configuration isn't blocking access. Try to connect to another instance in the same VPC as your unreachable instance. If you can't access another instance, work with your local network administrator to determine whether a local policy is restricting access.

Remote Desktop Services issues

If the instance can't be reached during logon, there could a problem with Remote Desktop Services (RDS) on the instance.

Tip

You can use the `AWSsupport-TroubleshootRDP` runbook to check and modify various settings that might affect Remote Desktop Protocol (RDP) connections. For more information,

see [AWS Support - Troubleshoot RDP](#) in the *AWS Systems Manager Automation runbook reference*.

Remote Desktop Services configuration

Configuration	Verify
RDS is running	Verify that RDS is running on the instance. Connect to the instance using the Microsoft Management Console (MMC) Services snap-in (<code>services.msc</code>). In the list of services, verify that Remote Desktop Services is Running . If it isn't, start it and then set the startup type to Automatic . If you can't connect to the instance by using the Services snap-in, detach the root volume from the instance, take a snapshot of the volume or create an AMI from it, attach the original volume to another instance in the same Availability Zone as a secondary volume, and modify the Start registry key. When you are finished, reattach the root volume to the original instance. For more information about detaching volumes, see Detach an Amazon EBS volume from a Windows instance (p. 1752) .
RDS is enabled	Even if the service is started, it might be disabled. Detach the root volume from the instance, take a snapshot of the volume or create an AMI from it, attach the original volume to another instance in the same Availability Zone as a secondary volume, and enable the service by modifying the Terminal Server registry key as described in Enable Remote Desktop on an EC2 Instance With Remote Registry (p. 2125) . When you are finished, reattach the root volume to the original instance. For more information, see Detach an Amazon EBS volume from a Windows instance (p. 1752) .

High CPU usage

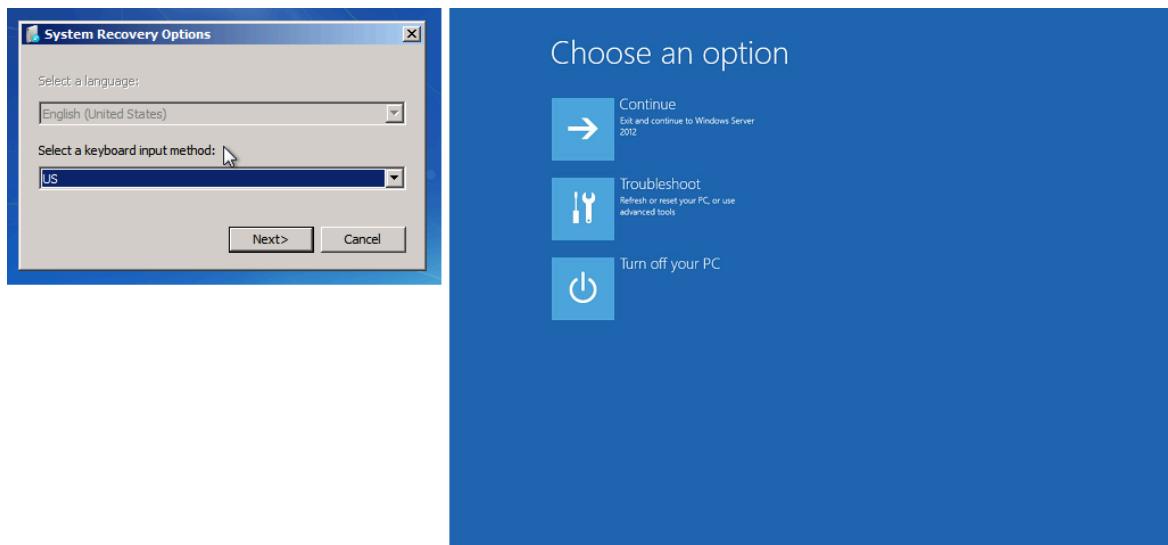

Check the **CPUUtilization (Maximum)** metric on your instance by using Amazon CloudWatch. If **CPUUtilization (Maximum)** is a high number, wait for the CPU to go down and try connecting again. High CPU usage can be caused by:

- Windows Update
- Security Software Scan
- Custom Startup Script
- Task Scheduler

For more information, see [Get Statistics for a Specific Resource](#) in the *Amazon CloudWatch User Guide*. For additional troubleshooting tips, see [High CPU usage shortly after Windows starts \(p. 2118\)](#).

Recovery console screen

Console Screenshot Service returned the following.

The operating system might boot into the Recovery console and get stuck in this state if the `bootstatuspolicy` is not set to `ignoreallfailures`. Use the following procedure to change the `bootstatuspolicy` configuration to `ignoreallfailures`.

By default, the policy configuration for public Windows AMIs provided by AWS is set to `ignoreallfailures`.

1. Stop the unreachable instance.
2. Create a snapshot of the root volume. The root volume is attached to the instance as `/dev/sda1`.

Detach the root volume from the unreachable instance, take a snapshot of the volume or create an AMI from it, and attach it to another instance in the same Availability Zone as a secondary volume. For more information, see [Detach an Amazon EBS volume from a Windows instance \(p. 1752\)](#).

Warning

If your temporary instance and the original instance were launched using the same AMI, you must complete additional steps or you won't be able to boot the original instance after you restore its root volume because of a disk signature collision. If you must create a temporary instance using the same AMI, to avoid a disk signature collision, complete the steps in [Disk signature collision \(p. 2107\)](#).

Alternatively, select a different AMI for the temporary instance. For example, if the original instance uses an AMI for Windows Server 2008 R2, launch the temporary instance using an AMI for Windows Server 2012.

3. Log in to the instance and run the following command from a command prompt to change the `bootstatuspolicy` configuration to `ignoreallfailures`.

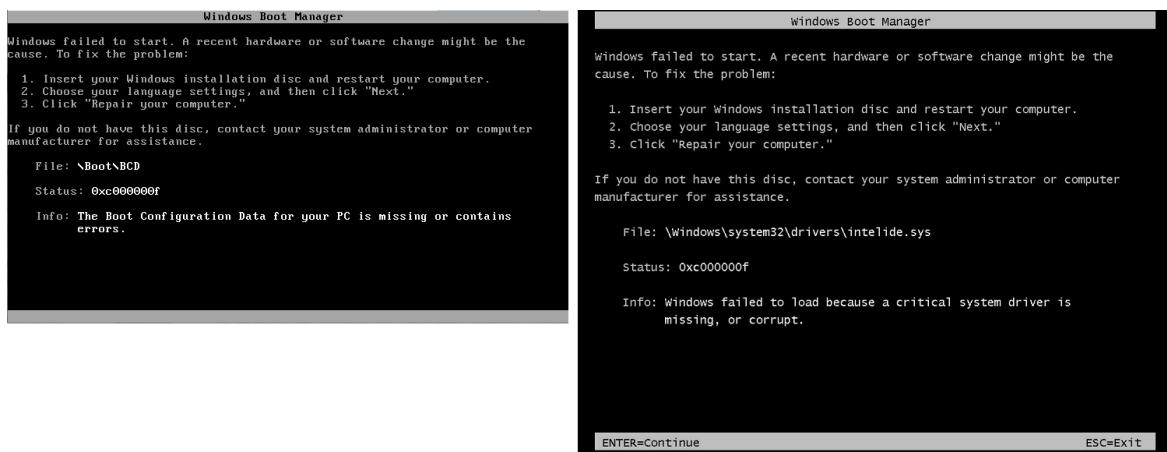

```
bcdeedit /store Drive Letter:\boot\bcd /set {default} bootstatuspolicy ignoreallfailures
```

4. Reattach the volume to the unreachable instance and start the instance again.

Windows boot manager screen

Console Screenshot Service returned the following.

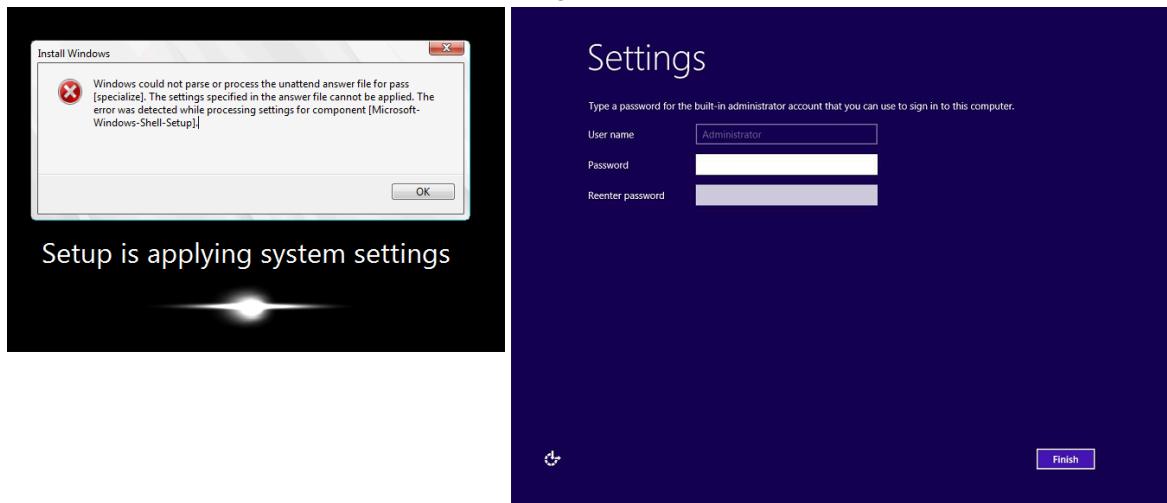

Amazon Elastic Compute Cloud User Guide for Windows Instances Common screenshots

The operating system experienced a fatal corruption in the system file and/or the registry. When the instance is stuck in this state, you should recover the instance from a recent backup AMI or launch a replacement instance. If you need to access data on the instance, detach any root volumes from the unreachable instance, take a snapshot of those volume or create an AMI from them, and attach them to another instance in the same Availability Zone as a secondary volume. For more information, see [Detach an Amazon EBS volume from a Windows instance \(p. 1752\)](#).

Sysprep screen

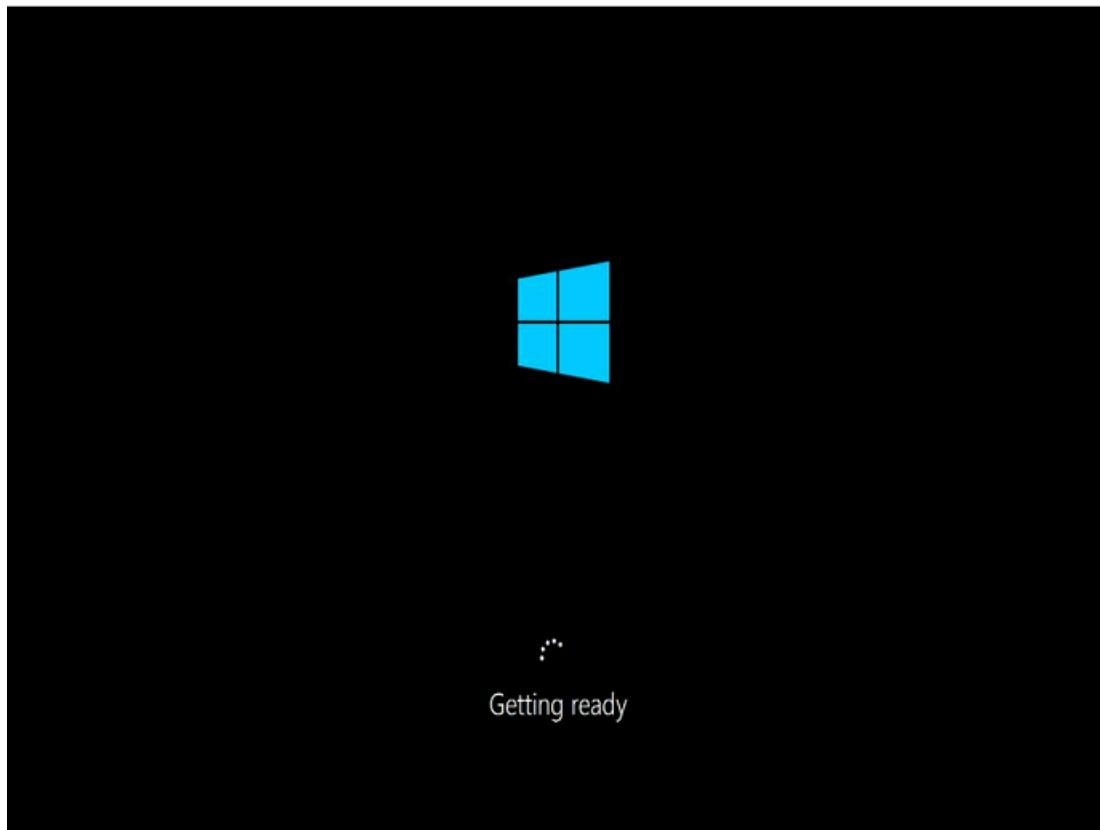

Console Screenshot Service returned the following.

You may see this screen if you did not use the EC2Config Service to call Sysprep or if the operating system failed while running Sysprep. You can reset the password using [EC2Rescue \(p. 2160\)](#). Otherwise, [Create a standardized Amazon Machine Image \(AMI\) using Sysprep \(p. 154\)](#).

Getting ready screen

Console Screenshot Service returned the following.

Refresh the Instance Console Screenshot Service repeatedly to verify that the progress ring is spinning. If the ring is spinning, wait for the operating system to start up. You can also check the **CPUUtilization (Maximum)** metric on your instance by using Amazon CloudWatch to see if the operating system is active. If the progress ring is not spinning, the instance may be stuck at the boot process. Reboot the instance. If rebooting does not solve the problem, recover the instance from a recent backup AMI or launch a replacement instance. If you need to access data on the instance, detach the root volume from the unreachable instance, take a snapshot of the volume or create an AMI from it. Then attach it to another instance in the same Availability Zone as a secondary volume.

Windows Update screen

Console Screenshot Service returned the following.

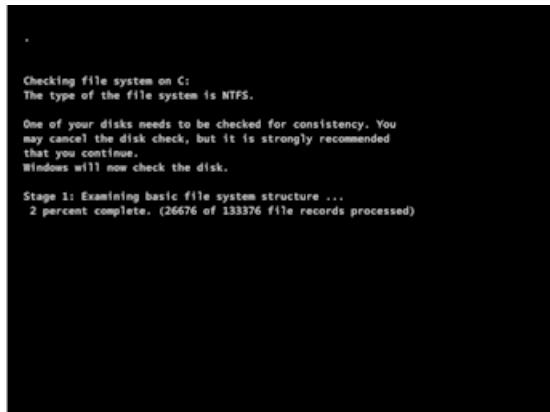

The Windows Update process is updating the registry. Wait for the update to finish. Do not reboot or stop the instance as this may cause data corruption during the update.

Note

The Windows Update process can consume resources on the server during the update. If you experience this problem often, consider using faster instance types and faster EBS volumes.

Chkdsk

Console Screenshot Service returned the following.

Windows is running the chkdsk system tool on the drive to verify file system integrity and fix logical file system errors. Wait for process to complete.

Reset a lost or expired Windows administrator password

If you are no longer able to access your Windows Amazon EC2 instance because the Windows administrator password is lost or expired, you can reset the password.

Note

There is an AWS Systems Manager Automation document that automatically applies the manual steps necessary to reset the local administrator password. For more information, see [Reset Passwords and SSH Keys on Amazon EC2 Instances](#) in the *AWS Systems Manager User Guide*.

The manual methods to reset the administrator password use EC2Launch v2, EC2Config, or EC2Launch.

- For all supported Windows AMIs that include the EC2Launch v2 agent, use EC2Launch v2.
- For Windows AMIs before Windows Server 2016, use the EC2Config service.
- For Windows Server 2016 and later AMIs, use the EC2Launch service.

These procedures also describe how to connect to an instance if you lost the key pair that was used to create the instance. Amazon EC2 uses a public key to encrypt a piece of data, such as a password, and a private key to decrypt the data. The public and private keys are known as a *key pair*. With Windows instances, you use a key pair to obtain the administrator password and then log in using RDP.

Note

If you have disabled the local administrator account on the instance and your instance is configured for Systems Manager, you can also re-enable and reset your local administrator password by using EC2Rescue and Run Command. For more information, see [Using EC2Rescue for Windows Server with Systems Manager Run Command](#).

Contents

- [Reset the Windows administrator password using EC2Launch v2 \(p. 2135\)](#)
- [Reset the Windows administrator password using EC2Config \(p. 2138\)](#)
- [Reset the Windows administrator password using EC2Launch \(p. 2142\)](#)

Reset the Windows administrator password using EC2Launch v2

If you have lost your Windows administrator password and are using a supported Windows AMI that includes the EC2Launch v2 agent, you can use EC2Launch v2 to generate a new password.

If you are using a Windows Server 2016 or later AMI that does not include the EC2Launch v2 agent, see [Reset the Windows administrator password using EC2Launch \(p. 2142\)](#).

If you are using a Windows Server AMI earlier than Windows Server 2016 that does not include the EC2Launch v2 agent, see [Reset the Windows administrator password using EC2Config \(p. 2138\)](#).

Note

If you have disabled the local administrator account on the instance and your instance is configured for Systems Manager, you can also re-enable and reset your local administrator password by using EC2Rescue and Run Command. For more information, see [Using EC2Rescue for Windows Server with Systems Manager Run Command](#).

Note

There is an AWS Systems Manager Automation document that automatically applies the manual steps necessary to reset the local administrator password. For more information, see [Reset Passwords and SSH Keys on Amazon EC2 Instances](#) in the *AWS Systems Manager User Guide*.

To reset your Windows administrator password using EC2Launch v2, you need to do the following:

- [Step 1: Verify that the EC2Launch v2 agent is running \(p. 2135\)](#)
- [Step 2: Detach the root volume from the instance \(p. 2136\)](#)
- [Step 3: Attach the volume to a temporary instance \(p. 2136\)](#)
- [Step 4: Delete the .run-once file \(p. 2137\)](#)
- [Step 5: Restart the original instance \(p. 2137\)](#)

Step 1: Verify that the EC2Launch v2 agent is running

Before you attempt to reset the administrator password, verify that the EC2Launch v2 agent is installed and running. You use the EC2Launch v2 agent to reset the administrator password later in this section.

To verify that the EC2Launch v2 agent is running

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and then select the instance that requires a password reset. This instance is referred to as the *original* instance in this procedure.
3. Choose **Actions, Monitor and troubleshoot, Get system log**.
4. Locate the EC2 Launch entry, for example, **Launch: EC2Launch v2 service v2.0.124**. If you see this entry, the EC2Launch v2 service is running.

If the system log output is empty, or if the EC2Launch v2 agent is not running, troubleshoot the instance using the Instance Console Screenshot service. For more information, see [Troubleshoot an unreachable instance \(p. 2126\)](#).

Step 2: Detach the root volume from the instance

You can't use EC2Launch v2 to reset an administrator password if the volume on which the password is stored is attached to an instance as the root volume. You must detach the volume from the original instance before you can attach it to a temporary instance as a secondary volume.

To detach the root volume from the instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance that requires a password reset and choose **Actions, Instance state, Stop instance**. After the status of the instance changes to **Stopped**, continue with the next step.
4. (Optional) If you have the private key that you specified when you launched this instance, continue with the next step. Otherwise, use the following steps to replace the instance with a new instance that you launch with a new key pair.
 - a. Create a new key pair using the Amazon EC2 console. To give your new key pair the same name as the one for which you lost the private key, you must first delete the existing key pair.
 - b. Select the instance to replace. Note the instance type, VPC, subnet, security group, and IAM role of the instance.
 - c. Choose **Actions, Image and templates, Create image**. Type a name and a description for the image and choose **Create image**. In the navigation pane, choose **AMIs**. After the image status changes to **available**, continue to the next step.
 - d. Select the image and choose **Actions**, and then **Launch**.
 - e. Complete the wizard, selecting the same instance type, VPC, subnet, security group, and IAM role as the instance to replace, and then choose **Launch**.
 - f. When prompted, choose the key pair that you created for the new instance, select the acknowledgement check box, and then choose **Launch Instances**.
 - g. (Optional) If the original instance has an associated Elastic IP address, transfer it to the new instance. If the original instance has EBS volumes in addition to the root volume, transfer them to the new instance.
 - h. Terminate the stopped instance, as it is no longer needed. For the remainder of this procedure, all references to the original instance apply to this instance that you just created.
5. Detach the root volume from the original instance as follows:
 - a. In the **Description** pane of the original instance, note the ID of the EBS volume listed as the **Root device**.
 - b. In the navigation pane, choose **Volumes**.
 - c. In the list of volumes, select the volume noted in the previous step, and choose **Actions, Detach Volume**. After the volume status changes to **available**, continue with the next step.

Step 3: Attach the volume to a temporary instance

Next, launch a temporary instance and attach the volume to it as a secondary volume. This is the instance you use to modify the configuration file.

To launch a temporary instance and attach the volume

1. Launch the temporary instance as follows:
 - a. In the navigation pane, choose **Instances**, choose **Launch instances**, and then select an AMI.

Important

To avoid disk signature collisions, you must select an AMI for a different version of Windows. For example, if the original instance runs Windows Server 2019, launch the temporary instance using the base AMI for Windows Server 2016.

- b. Leave the default instance type and choose **Next: Configure Instance Details**.
- c. On the **Configure Instance Details** page, for **Subnet**, select the same Availability Zone as the original instance and choose **Review and Launch**.

Important

The temporary instance must be in the same Availability Zone as the original instance. If your temporary instance is in a different Availability Zone, you can't attach the original instance's root volume to it.

- d. On the **Review Instance Launch** page, choose **Launch**.
- e. When prompted, create a new key pair, download it to a safe location on your computer, and then choose **Launch Instances**.
2. Attach the volume to the temporary instance as a secondary volume as follows:
 - a. In the navigation pane, choose **Volumes**, select the volume that you detached from the original instance, and then choose **Actions, Attach Volume**.
 - b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your temporary instance and select the instance from the list.
 - c. For **Device**, type **xvdf** (if it isn't already there), and choose **Attach**.

Step 4: Delete the .run-once file

After you have attached the volume to the temporary instance as a secondary volume, delete the `.run-once` file from the instance, located at `%ProgramData%/Amazon/EC2Launch/state/.run-once`. This directs EC2Launch v2 to run all tasks with a frequency of once, which includes setting the administrator password.

Important

Any scripts set to run once will be triggered by this action.

Step 5: Restart the original instance

After you have deleted the `.run-once` file, reattach the volume to the original instance as the root volume and connect to the instance using its key pair to retrieve the administrator password.

1. Reattach the volume to the original instance as follows:
 - a. In the navigation pane, choose **Volumes**, select the volume that you detached from the temporary instance, and then choose **Actions, Attach Volume**.
 - b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your original instance and then select the instance.
 - c. For **Device**, type **/dev/sda1**.
 - d. Choose **Attach**. After the volume status changes to **in-use**, continue to the next step.
2. In the navigation pane, choose **Instances**. Select the original instance and choose **Instance state, Start instance**. After the instance state changes to **Running**, continue to the next step.
3. Retrieve your new Windows administrator password using the private key for the new key pair and connect to the instance. For more information, see [Connect to your Windows instance \(p. 626\)](#).

Important

The instance gets a new public IP address after you stop and start it. Make sure to connect to the instance using its current public DNS name. For more information, see [Instance lifecycle \(p. 546\)](#).

4. (Optional) If you have no further use for the temporary instance, you can terminate it. Select the temporary instance, and choose **Instance State, Terminate instance**.

Reset the Windows administrator password using EC2Config

If you have lost your Windows administrator password and are using a Windows AMI before Windows Server 2016, you can use the EC2Config agent to generate a new password.

If you are using a Windows Server 2016 or later AMI, see [Reset the Windows administrator password using EC2Launch \(p. 2142\)](#) or, you can use the [EC2Rescue tool \(p. 2160\)](#), which uses the EC2Launch service to generate a new password.

Note

If you have disabled the local administrator account on the instance and your instance is configured for Systems Manager, you can also re-enable and reset your local administrator password by using EC2Rescue and Run Command. For more information, see [Using EC2Rescue for Windows Server with Systems Manager Run Command](#).

Note

There is an AWS Systems Manager Automation document that automatically applies the manual steps necessary to reset the local administrator password. For more information, see [Reset Passwords and SSH Keys on Amazon EC2 Instances](#) in the *AWS Systems Manager User Guide*.

To reset your Windows administrator password using EC2Config, you need to do the following:

- [Step 1: Verify that the EC2Config service is running \(p. 2138\)](#)
- [Step 2: Detach the root volume from the instance \(p. 2139\)](#)
- [Step 3: Attach the volume to a temporary instance \(p. 2139\)](#)
- [Step 4: Modify the configuration file \(p. 2140\)](#)
- [Step 5: Restart the original instance \(p. 2141\)](#)

Step 1: Verify that the EC2Config service is running

Before you attempt to reset the administrator password, verify that the EC2Config service is installed and running. You use the EC2Config service to reset the administrator password later in this section.

To verify that the EC2Config service is running

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and then select the instance that requires a password reset. This instance is referred to as the *original* instance in this procedure.
3. (New console) Choose **Actions, Monitor and troubleshoot, Get system log**.
(Old console) Choose **Actions, System Settings, Get System Log**.
4. Locate the EC2 Agent entry, for example, **EC2 Agent: Ec2Config service v3.18.1118**. If you see this entry, the EC2Config service is running.

If the system log output is empty, or if the EC2Config service is not running, troubleshoot the instance using the Instance Console Screenshot service. For more information, see [Troubleshoot an unreachable instance \(p. 2126\)](#).

Step 2: Detach the root volume from the instance

You can't use EC2Config to reset an administrator password if the volume on which the password is stored is attached to an instance as the root volume. You must detach the volume from the original instance before you can attach it to a temporary instance as a secondary volume.

To detach the root volume from the instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance that requires a password reset and choose **Actions, Instance state, Stop instance**. After the status of the instance changes to **Stopped**, continue with the next step.
4. (Optional) If you have the private key that you specified when you launched this instance, continue with the next step. Otherwise, use the following steps to replace the instance with a new instance that you launch with a new key pair.
 - a. Create a new key pair using the Amazon EC2 console. To give your new key pair the same name as the one for which you lost the private key, you must first delete the existing key pair.
 - b. Select the instance to replace. Note the instance type, VPC, subnet, security group, and IAM role of the instance.
 - c. Choose **Actions, Image and templates, Create image**. Type a name and a description for the image and choose **Create image**. In the navigation pane, choose **AMIs**. After the image status changes to **available**, continue to the next step.
 - d. Select the image and choose **Actions**, and then **Launch**.
 - e. Complete the wizard, selecting the same instance type, VPC, subnet, security group, and IAM role as the instance to replace, and then choose **Launch**.
 - f. When prompted, choose the key pair that you created for the new instance, select the acknowledgement check box, and then choose **Launch Instances**.
 - g. (Optional) If the original instance has an associated Elastic IP address, transfer it to the new instance. If the original instance has EBS volumes in addition to the root volume, transfer them to the new instance.
 - h. Terminate the stopped instance, as it is no longer needed. For the remainder of this procedure, all references to the original instance apply to this instance that you just created.
5. Detach the root volume from the original instance as follows:
 - a. In the **Description** pane of the original instance, note the ID of the EBS volume listed as the **Root device**.
 - b. In the navigation pane, choose **Volumes**.
 - c. In the list of volumes, select the volume noted in the previous step, and choose **Actions, Detach Volume**. After the volume status changes to **available**, continue with the next step.

Step 3: Attach the volume to a temporary instance

Next, launch a temporary instance and attach the volume to it as a secondary volume. This is the instance you use to modify the configuration file.

To launch a temporary instance and attach the volume

1. Launch the temporary instance as follows:
 - a. In the navigation pane, choose **Instances**, choose **Launch instances**, and then select an AMI.

Important
To avoid disk signature collisions, you must select an AMI for a different version of Windows. For example, if the original instance runs Windows Server 2019, launch the temporary instance using the base AMI for Windows Server 2016.
 - b. Leave the default instance type and choose **Next: Configure Instance Details**.
 - c. On the **Configure Instance Details** page, for **Subnet**, select the same Availability Zone as the original instance and choose **Review and Launch**.

Important
The temporary instance must be in the same Availability Zone as the original instance. If your temporary instance is in a different Availability Zone, you can't attach the original instance's root volume to it.
 - d. On the **Review Instance Launch** page, choose **Launch**.
 - e. When prompted, create a new key pair, download it to a safe location on your computer, and then choose **Launch Instances**.
2. Attach the volume to the temporary instance as a secondary volume as follows:
 - a. In the navigation pane, choose **Volumes**, select the volume that you detached from the original instance, and then choose **Actions, Attach Volume**.
 - b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your temporary instance and select the instance from the list.
 - c. For **Device**, type **xvdf** (if it isn't already there), and choose **Attach**.

Step 4: Modify the configuration file

After you have attached the volume to the temporary instance as a secondary volume, modify the `Ec2SetPassword` plugin in the configuration file.

To modify the configuration file

1. From the temporary instance, modify the configuration file on the secondary volume as follows:
 - a. Launch and connect to the temporary instance.
 - b. Open the **Disk Management** utility, and bring the drive online using these instructions: [Making an Amazon EBS volume available for use](#).
 - c. Navigate to the secondary volume, and open `\Program Files\Amazon\Ec2ConfigService\Settings\config.xml` using a text editor, such as Notepad.
 - d. At the top of the file, find the plugin with the name `Ec2SetPassword`, as shown in the screenshot. Change the state from `Disabled` to `Enabled` and save the file.

```
<?xml version="1.0" standalone="yes"?>
<Ec2ConfigurationSettings>
  <Plugins>
    <Plugin>
      <Name>Ec2SetPassword</Name>
      <State>Disabled</State>
    </Plugin>
    <Plugin>
      <Name>Ec2SetComputerName</Name>
      <State>Disabled</State>
    </Plugin>
    <Plugin>
      <Name>Ec2InitializeDrives</Name>
      <State>Enabled</State>
    </Plugin>
    <Plugin>
      <Name>Ec2EventLog</Name>
      <State>Disabled</State>
    </Plugin>
    <Plugin>
      <Name>Ec2ConfigureRDP</Name>
      <State>Disabled</State>
    </Plugin>
    <Plugin>
      <Name>Ec2OutputRDPCert</Name>
      <State>Enabled</State>
    </Plugin>
    <Plugin>
      <Name>Ec2SetDriveLetter</Name>
      <State>Enabled</State>
    </Plugin>
  </Plugins>
</Ec2ConfigurationSettings>
```

2. After you have modified the configuration file, detach the secondary volume from the temporary instance as follows:
 - a. Using the **Disk Management** utility, bring the volume offline.
 - b. Disconnect from the temporary instance and return to the Amazon EC2 console.
 - c. In the navigation pane, choose **Volumes**, select the volume, and then choose **Actions, Detach Volume**. After the volume's status changes to **available**, continue with the next step.

Step 5: Restart the original instance

After you have modified the configuration file, reattach the volume to the original instance as the root volume and connect to the instance using its key pair to retrieve the administrator password.

1. Reattach the volume to the original instance as follows:
 - a. In the navigation pane, choose **Volumes**, select the volume that you detached from the temporary instance, and then choose **Actions, Attach Volume**.
 - b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your original instance and then select the instance.
 - c. For **Device**, type **/dev/sda1**.
 - d. Choose **Attach**. After the volume status changes to **in-use**, continue to the next step.
2. In the navigation pane, choose **Instances**. Select the original instance and choose **Instance state, Start instance**. After the instance state changes to **Running**, continue to the next step.
3. Retrieve your new Windows administrator password using the private key for the new key pair and connect to the instance. For more information, see [Connect to your Windows instance \(p. 626\)](#).

Important

The instance gets a new public IP address after you stop and start it. Make sure to connect to the instance using its current public DNS name. For more information, see [Instance lifecycle \(p. 546\)](#).

4. (Optional) If you have no further use for the temporary instance, you can terminate it. Select the temporary instance, and choose **Instance State, Terminate instance**.

Reset the Windows administrator password using EC2Launch

If you have lost your Windows administrator password and are using a Windows Server 2016 or later AMI, you can use the [EC2Rescue tool \(p. 2160\)](#), which uses the EC2Launch service to generate a new password.

If you are using a Windows Server 2016 or later AMI that does not include the EC2Launch v2 agent, you can use EC2Launch v2 to generate a new password.

If you are using a Windows Server AMI earlier than Windows Server 2016, see [Reset the Windows administrator password using EC2Config \(p. 2138\)](#).

Warning

When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

Note

If you have disabled the local administrator account on the instance and your instance is configured for Systems Manager, you can also re-enable and reset your local administrator password by using EC2Rescue and Run Command. For more information, see [Using EC2Rescue for Windows Server with Systems Manager Run Command](#).

Note

There is an AWS Systems Manager Automation document that automatically applies the manual steps necessary to reset the local administrator password. For more information, see [Reset Passwords and SSH Keys on Amazon EC2 Instances](#) in the *AWS Systems Manager User Guide*.

To reset your Windows administrator password using EC2Launch, you need to do the following:

- [Step 1: Detach the root volume from the instance \(p. 2142\)](#)
- [Step 2: Attach the volume to a temporary instance \(p. 2143\)](#)
- [Step 3: Reset the administrator password \(p. 2144\)](#)
- [Step 4: Restart the original instance \(p. 2144\)](#)

Step 1: Detach the root volume from the instance

You can't use EC2Launch to reset an administrator password if the volume on which the password is stored is attached to an instance as the root volume. You must detach the volume from the original instance before you can attach it to a temporary instance as a secondary volume.

To detach the root volume from the instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance that requires a password reset and choose **Actions, Instance state, Stop instance**. After the status of the instance changes to **Stopped**, continue with the next step.

4. (Optional) If you have the private key that you specified when you launched this instance, continue with the next step. Otherwise, use the following steps to replace the instance with a new instance that you launch with a new key pair.
 - a. Create a new key pair using the Amazon EC2 console. To give your new key pair the same name as the one for which you lost the private key, you must first delete the existing key pair.
 - b. Select the instance to replace. Note the instance type, VPC, subnet, security group, and IAM role of the instance.
 - c. Choose **Actions, Image and templates, Create image**. Type a name and a description for the image and choose **Create image**. In the navigation pane, choose **AMIs**. After the image status changes to **available**, continue to the next step.
 - d. Select the image and choose **Actions**, and then **Launch**.
 - e. Complete the wizard, selecting the same instance type, VPC, subnet, security group, and IAM role as the instance to replace, and then choose **Launch**.
 - f. When prompted, choose the key pair that you created for the new instance, select the acknowledgement check box, and then choose **Launch Instances**.
 - g. (Optional) If the original instance has an associated Elastic IP address, transfer it to the new instance. If the original instance has EBS volumes in addition to the root volume, transfer them to the new instance.
 - h. Terminate the stopped instance, as it is no longer needed. For the remainder of this procedure, all references to the original instance apply to this instance that you just created.
5. Detach the root volume from the original instance as follows:
 - a. In the **Description** pane of the original instance, note the ID of the EBS volume listed as the **Root device**.
 - b. In the navigation pane, choose **Volumes**.
 - c. In the list of volumes, select the volume noted in the previous step, and choose **Actions, Detach Volume**. After the volume status changes to **available**, continue with the next step.

Step 2: Attach the volume to a temporary instance

Next, launch a temporary instance and attach the volume to it as a secondary volume. This is the instance you use to run EC2Launch.

To launch a temporary instance and attach the volume

1. Launch the temporary instance as follows:
 - a. In the navigation pane, choose **Instances**, choose **Launch instances**, and then select an AMI.

Important
To avoid disk signature collisions, you must select an AMI for a different version of Windows. For example, if the original instance runs Windows Server 2019, launch the temporary instance using the base AMI for Windows Server 2016.
 - b. Leave the default instance type and choose **Next: Configure Instance Details**.
 - c. On the **Configure Instance Details** page, for **Subnet**, select the same Availability Zone as the original instance and choose **Review and Launch**.

Important
The temporary instance must be in the same Availability Zone as the original instance. If your temporary instance is in a different Availability Zone, you can't attach the original instance's root volume to it.
 - d. On the **Review Instance Launch** page, choose **Launch**.

- e. When prompted, create a new key pair, download it to a safe location on your computer, and then choose **Launch Instances**.
2. Attach the volume to the temporary instance as a secondary volume as follows:
 - a. In the navigation pane, choose **Volumes**, select the volume that you detached from the original instance, and then choose **Actions, Attach Volume**.
 - b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your temporary instance and select the instance from the list.
 - c. For **Device**, type **xvdf** (if it isn't already there), and choose **Attach**.

Step 3: Reset the administrator password

Next, connect to the temporary instance and use EC2Launch to reset the administrator password.

To reset the administrator password

1. Connect to the temporary instance and use the EC2Rescue for Windows Server tool on the instance to reset the administrator password as follows:
 - a. Download the [EC2Rescue for Windows Server](#) zip file, extract the contents, and run **EC2Rescue.exe**.
 - b. On the **License Agreement** screen, read the license agreement, and, if you accept the terms, choose **I Agree**.
 - c. On the **Welcome to EC2Rescue for Windows Server** screen, choose **Next**.
 - d. On the **Select mode** screen, choose **Offline instance**.
 - e. On the **Select a disk** screen, select the **xvdf** device and choose **Next**.
 - f. Confirm the disk selection and choose **Yes**.
 - g. After the volume has loaded, choose **OK**.
 - h. On the **Select Offline Instance Option** screen, choose **Diagnose and Rescue**.
 - i. On the **Summary** screen, review the information and choose **Next**.
 - j. On the **Detected possible issues** screen, select **Reset Administrator Password** and choose **Next**.
 - k. On the **Confirm** screen, choose **Rescue, OK**.
 - l. On the **Done** screen, choose **Finish**.
 - m. Close the EC2Rescue for Windows Server tool, disconnect from the temporary instance, and then return to the Amazon EC2 console.
2. Detach the secondary (xvdf) volume from the temporary instance as follows:
 - a. In the navigation pane, choose **Instances** and select the temporary instance.
 - b. On the **Storage** tab for the temporary instance, note the ID of the EBS volume listed as **xvdf**.
 - c. In the navigation pane, choose **Volumes**.
 - d. In the list of volumes, select the volume noted in the previous step, and choose **Actions, Detach Volume**. After the volume status changes to **available**, continue with the next step.

Step 4: Restart the original instance

After you have reset the administrator password using EC2Launch, reattach the volume to the original instance as the root volume and connect to the instance using its key pair to retrieve the administrator password.

To restart the original instance

1. Reattach the volume to the original instance as follows:
 - a. In the navigation pane, choose **Volumes**, select the volume that you detached from the temporary instance, and then choose **Actions, Attach Volume**.
 - b. In the **Attach Volume** dialog box, for **Instances**, start typing the name or ID of your original instance and then select the instance.
 - c. For **Device**, type `/dev/sda1`.
 - d. Choose **Attach**. After the volume status changes to **in-use**, continue to the next step.
2. In the navigation pane, choose **Instances**. Select the original instance and choose **Instance state, Start instance**. After the instance state changes to **Running**, continue to the next step.
3. Retrieve your new Windows administrator password using the private key for the new key pair and connect to the instance. For more information, see [Connect to your Windows instance \(p. 626\)](#).
4. (Optional) If you have no further use for the temporary instance, you can terminate it. Select the temporary instance, and choose **Instance State, Terminate instance**.

Troubleshoot stopping your instance

If you have stopped your Amazon EBS-backed instance and it appears stuck in the **stopping** state, there may be an issue with the underlying host computer.

There is no cost for instance usage while an instance is in the **stopping** state or in any other state except **running**. You are only charged for instance usage when an instance is in the **running** state.

Force stop the instance

Force the instance to stop using either the console or the AWS CLI.

Note

You can force an instance to stop using the console only while the instance is in the **stopping** state. You can force an instance to stop using the AWS CLI while the instance is in any state, except **shutting-down** and **terminated**.

New console

To force stop the instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Instance state, Force stop instance, Stop**.

Note that **Force stop instance** is only available in the console if your instance is in the **stopping** state. If your instance is in another state (except **shutting-down** and **terminated**) you can use the AWS CLI to force stop your instance.

Old console

To force stop the instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the stuck instance.

3. Choose **Instance State, Stop, Yes, Forcefully Stop.**

AWS CLI

To force stop the instance using the AWS CLI

Use the [stop-instances](#) command and the --force option as follows:

```
aws ec2 stop-instances --instance-ids i-0123ab456c789d01e --force
```

If, after 10 minutes, the instance has not stopped, post a request for help on [AWS re:Post](#). To help expedite a resolution, include the instance ID, and describe the steps that you've already taken. Alternatively, if you have a support plan, create a technical support case in the [Support Center](#).

Create a replacement instance

To attempt to resolve the problem while you are waiting for assistance from [AWS re:Post](#) or the [Support Center](#), create a replacement instance. Create an AMI of the stuck instance, and launch a new instance using the new AMI.

Important

Creating a replacement instance is recommended if it's registering [system status checks \(p. 1153\)](#) only, as instance status checks will result in the AMI copying over an exact replica of the broken OS. Once you've confirmed the status message, create the AMI and launch a new instance using the new AMI.

New console

To create a replacement instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Actions, Image and templates, Create image**.
4. On the **Create image** page, do the following:
 - a. Enter a name and description for the AMI.
 - b. Choose **No reboot**.
 - c. Choose **Create image**.

For more information, see [Create a Windows AMI from a running instance \(p. 152\)](#).

5. Launch a new instance from the AMI and verify that the new instance is working.
6. Select the stuck instance, and choose **Actions, Instance state, Terminate instance**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

Old console

To create a replacement instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Actions, Image, Create Image**.

4. In the **Create Image** dialog box, fill in the following fields, and then choose **Create Image**:
 - a. Specify a name and description for the AMI.
 - b. Choose **No reboot**.

For more information, see [Create a Windows AMI from a running instance \(p. 152\)](#).

 5. Launch a new instance from the AMI and verify that the new instance is working.
 6. Select the stuck instance, and choose **Actions, Instance State, Terminate**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

AWS CLI

To create a replacement instance using the CLI

1. Create an AMI from the stuck instance using the [create-image](#) (AWS CLI) command and the `--no-reboot` option as follows:

```
aws ec2 create-image --instance-id i-0123ab456c789d01e --name "AMI" --  
description "AMI for replacement instance" --no-reboot
```

2. Launch a new instance from the AMI using the [run-instances](#) (AWS CLI) command as follows:

```
aws ec2 run-instances --image-id ami-1a2b3c4d --count 1 --instance-type c3.large --  
key-name MyKeyPair --security-groups MySecurityGroup
```

3. Verify that the new instance is working.
4. Terminate the stuck instance using the [terminate-instances](#) (AWS CLI) command as follows:

```
aws ec2 terminate-instances --instance-ids i-1234567890abcdef0
```

If you are unable to create an AMI from the instance as described in the previous procedure, you can set up a replacement instance as follows:

(Alternate) To create a replacement instance using the console

1. Select the instance and choose **Description, Block devices**. Select each volume and make note of its volume ID. Be sure to note which volume is the root volume.
2. In the navigation pane, choose **Volumes**. Select each volume for the instance, and choose **Actions, Create Snapshot**.
3. In the navigation pane, choose **Snapshots**. Select the snapshot that you just created, and choose **Actions, Create Volume**.
4. Launch an instance with the same operating system as the stuck instance. Note the volume ID and device name of its root volume.
5. In the navigation pane, choose **Instances**, select the instance that you just launched, and choose **Instance state, Stop instance**.
6. In the navigation pane, choose **Volumes**, select the root volume of the stopped instance, and choose **Actions, Detach Volume**.
7. Select the root volume that you created from the stuck instance, choose **Actions, Attach Volume**, and attach it to the new instance as its root volume (using the device name that you made note of). Attach any additional non-root volumes to the instance.
8. In the navigation pane, choose **Instances** and select the replacement instance. Choose **Instance state, Start instance**. Verify that the instance is working.

9. Select the stuck instance, choose **Instance state**, **Terminate instance**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

Troubleshoot instance termination (shutting down)

You are not billed for any instance usage while an instance is not in the `running` state. In other words, when you terminate an instance, you stop incurring charges for that instance as soon as its state changes to `shutting-down`.

Instance terminates immediately

Several issues can cause your instance to terminate immediately on start-up. See [Instance terminates immediately \(p. 2117\)](#) for more information.

Delayed instance termination

If your instance remains in the `shutting-down` state longer than a few minutes, it might be delayed due to shutdown scripts being run by the instance.

Another possible cause is a problem with the underlying host computer. If your instance remains in the `shutting-down` state for several hours, Amazon EC2 treats it as a stuck instance and forcibly terminates it.

If it appears that your instance is stuck terminating and it has been longer than several hours, post a request for help to [AWS re:Post](#). To help expedite a resolution, include the instance ID and describe the steps that you've already taken. Alternatively, if you have a support plan, create a technical support case in the [Support Center](#).

Terminated instance still displayed

After you terminate an instance, it remains visible for a short while before being deleted. The state shows as `terminated`. If the entry is not deleted after several hours, contact Support.

Error: The instance may not be terminated. Modify its 'disableApiTermination' instance attribute

If you try to terminate an instance and get the The instance `instance_id` may not be terminated. Modify its 'disableApiTermination' instance attribute error message, it indicates that the instance has been enabled for termination protection. Termination protection prevents the instance from being accidentally terminated. For more information, see [Enable termination protection \(p. 618\)](#).

You must disable termination protection before you can terminate the instance.

To disable termination protection using the Amazon EC2 console, select the instance and then choose **Actions**, **Instance Settings**, **Change Termination Protection**.

To disable termination protection using the AWS CLI, use the following command.

```
C:\> aws ec2 modify-instance-attribute --instance-id instance_id --no-disable-api-termination
```

Instances automatically launched or terminated

Generally, the following behaviors mean that you've used Amazon EC2 Auto Scaling, EC2 Fleet, or Spot Fleet to scale your computing resources automatically based on criteria that you've defined:

- You terminate an instance and a new instance launches automatically.
- You launch an instance and one of your instances terminates automatically.
- You stop an instance and it terminates and a new instance launches automatically.

To stop automatic scaling, see the [Amazon EC2 Auto Scaling User Guide, EC2 Fleet \(p. 962\)](#), or [Create a Spot Fleet request \(p. 1058\)](#).

Troubleshoot Sysprep

If you experience problems or receive error messages during image preparations, review the following logs. Log location varies depending on whether you are running EC2Config, EC2Launch v1, or EC2Launch v2 with Sysprep.

- %WINDIR%\Panther\Unattendgc (EC2Config, EC2Launch v1, and EC2Launch v2)
- %WINDIR%\System32\Sysprep\Panther (EC2Config, EC2Launch v1, and EC2Launch v2)
- C:\Program Files\Amazon\Ec2ConfigService\Logs\Ec2ConfigLog.txt (EC2Config only)
- C:\ProgramData\Amazon\Ec2Config\Logs (EC2Config only)
- C:\ProgramData\Amazon\EC2-Windows\Launch\Log\EC2Launch.log (EC2Launch v1 only)
- %ProgramData%\Amazon\EC2Launch\log\agent.log (EC2Launch v2 only)

If you receive an error message during image preparation with Sysprep, the OS might not be reachable. To review the log files, you must stop the instance, attach its root volume to another healthy instance as a secondary volume, and then review the logs mentioned earlier on the secondary volume. For more information about the purpose of the log files by name, see [Windows Setup-Related Log Files](#) in the Microsoft documentation.

If you locate errors in the Unattendgc log file, use the [Microsoft Error Lookup Tool](#) to get more details about the error. The following issue reported in the Unattendgc log file is typically the result of one or more corrupted user profiles on the instance:

```
Error [Shell Unattend] _FindLatestProfile failed (0x80070003) [gle=0x00000003]
Error [Shell Unattend] CopyProfile failed (0x80070003) [gle=0x00000003]
```

There are two options for resolving this issue:

Option 1

Use Regedit on the instance to search for the following key. Verify that there are no profile registry keys for a deleted user.

```
[HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\ProfileList\
```

Option 2

1. Edit the relevant file, as follows:

- Windows Server 2012 R2 and earlier – Edit the EC2Config answer file (C:\Program Files\Amazon\Ec2ConfigService\sysprep2008.xml).

- Windows Server 2016 and 2019 – Edit the unattend.xml answer file (`C:\ProgramData\Amazon\EC2-Windows\Launch\Sysprep\Unattend.xml`).
 - Windows Server 2022 – Edit the unattend.xml answer file (`C:\ProgramData\Amazon\EC2Launch\sysprep\unattend.xml`).
2. Change `<CopyProfile>true</CopyProfile>` to `<CopyProfile>false</CopyProfile>`.
 3. Run Sysprep again. Note that this configuration change will delete the built-in administrator user profile after Sysprep completes.

Troubleshoot the Elastic Network Adapter (ENA) Windows driver

The Elastic Network Adapter (ENA) is designed to improve operating system health and to reduce unexpected hardware behavior or failures that can disrupt the operation of your Windows instance. The ENA architecture keeps device or driver failures as transparent to the operating system as possible.

This topic provides troubleshooting information for the ENA Windows driver.

Can't connect

If you are unable to connect to your instance, see [Troubleshoot an unreachable instance \(p. 2126\)](#).

Note

You can also connect to the instance through AWS Systems Manager Session Manager. However, to do so requires prior configuration. For more information, see [Session Manager](#) in the *AWS Systems Manager User Guide*.

Collect diagnostic information on the instance

The steps to open Windows operating system (OS) tools vary, depending on what version of the OS is installed on your instance. In the following sections, we use the **Run** dialog to open the tools, which works the same across all OS versions. However, you can access these tools using any method that you prefer.

Access the Run dialog

- Using the Windows logo key combination: Windows + R
- Using the search bar:
 - Enter `run` in the search bar.
 - Select the **Run** application from the search results.

Some steps require the context menu to access properties or context-sensitive actions. There are several ways to do this, depending on your OS version and hardware.

Access the context menu

- Using your mouse: right-click an item to bring up its context menu.
- Using your keyboard:
 - Depending on your OS version, use Shift + F10, or Ctrl + Shift + F10.
 - If you have the context key on your keyboard (three horizontal lines in a box), select the item you want and then press the context key.

If you can connect to your instance, use the following techniques to gather diagnostic information for troubleshooting.

Check ENA device status

To check the status of your ENA Windows driver using the Windows Device Manager, follow these steps:

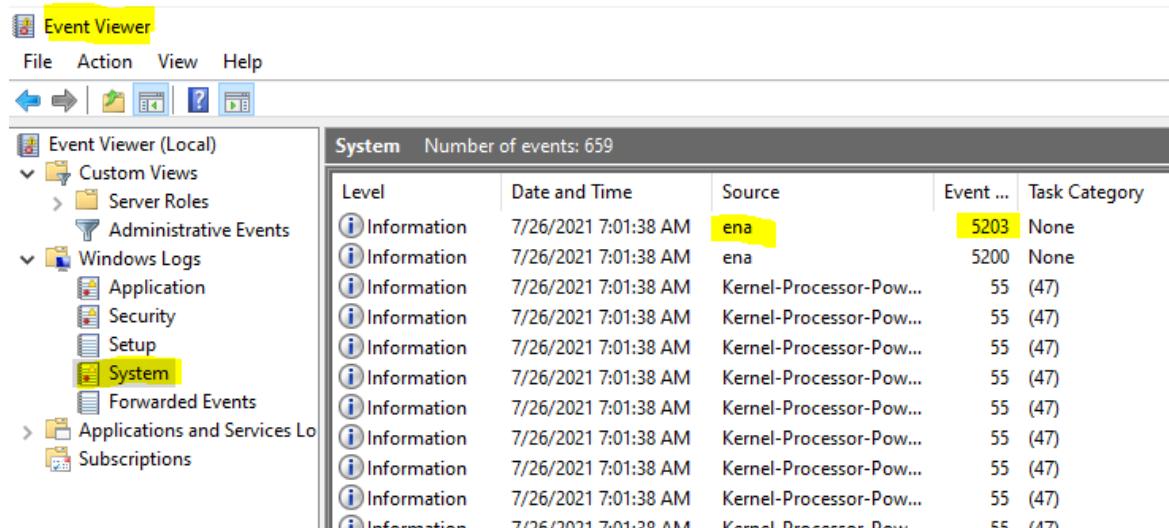

1. Open the **Run** dialog using one of the methods described in the preceding section.
 2. To open the Windows Device Manager, enter `devmgmt.msc` in the **Run** box.
 3. Choose **OK**. This opens the Device Manager window.
 4. Select the arrow to the left of **Network adapters** to expand the list.
 5. Choose the name, or open the context menu for the **Amazon Elastic Network Adapter**, and then choose **Properties**. This opens the **Amazon Elastic Network Adapter Properties** dialog.
 6. Verify that the message in the **General** tab says "This device is working properly."

Investigate driver event messages

To review ENA Windows driver event logs using the Windows Event Viewer, follow these steps:

1. Open the **Run** dialog using one of the methods described in the preceding section.
 2. To open the Windows Event Viewer, enter `eventvwr.msc` in the **Run** box.
 3. Choose **OK**. This opens the Event Viewer window.
 4. Expand the **Windows Logs** menu, and then choose **System**.
 5. Under **Actions**, in the top-right panel, choose **Filter Current Log**. This displays the filtering dialog.
 6. In the **Event sources** box, enter `ena`. This limits results to events that were generated by the ENA Windows driver.
 7. Choose **OK**. This shows filtered event log results in the detail sections of the window.
 8. To drill down into the details, select an event message from the list.

The following example shows an ENA driver event in the Windows Event Viewer system events list:

Event message summary

The following table shows event messages that the ENA Windows driver generates.

Input

Event ID	ENA driver event description	Type
5001	Hardware is out of resources	Error
5002	Adapter has detected a hardware error	Error
5005	Adapter has timed out on NDIS operation that did not complete in a timely manner	Error
5032	Adapter has failed to reset the device	Error
5200	Adapter has been initialized	Informational
5201	Adapter has been halted	Informational
5202	Adapter has been paused	Informational
5203	Adapter has been restarted	Informational
5204	Adapter has been shut down	Informational
5205	Adapter has been reset	Error
5206	Adapter has been surprise removed	Error
5208	Adapter initialization routine has failed	Error
5210	Adapter has encountered and successfully recovered an internal issue	Error

Review performance metrics

The ENA Windows driver publishes network performance metrics from the instances where metrics are enabled. You can view and enable metrics on the instance using the native Performance Monitor application. For more information about the metrics that the ENA Windows driver produces, see [Monitor network performance for your EC2 instance \(p. 1349\)](#).

On instances where ENA metrics are enabled, and the Amazon CloudWatch agent is installed, CloudWatch collects the metrics that are associated with the counters in Windows Performance Monitor, as well as some advanced metrics for ENA. These metrics are collected in addition to the metrics enabled by default on EC2 instances. For more information about the metrics, see [Metrics collected by the CloudWatch agent](#) in the *Amazon CloudWatch User Guide*.

Note

Performance metrics are not functional in version 2.2.4 of the ENA Windows driver. A fix is scheduled for the next release of the driver. To ensure that performance metrics are published, use version 2.2.3 for now.

Some of the ways that you can use performance metrics include:

- Troubleshoot instance performance issues.
- Choose the right instance size for a workload.

- Proactively plan scaling activities.
- Benchmark applications to determine if they maximize the performance available on an instance.

Refresh rate

By default, the driver refreshes metrics using a 1-second interval. However, the application that retrieves the metrics might use a different interval for polling. You can change the refresh interval in Device Manager, using the advanced properties for the driver.

To change the metrics refresh interval for the ENA Windows driver, follow these steps:

1. Open the **Run** dialog using one of the methods described in the preceding section.
2. To open the Windows Device Manager, enter `devmgmt.msc` in the **Run** box.
3. Choose **OK**. This opens the Device Manager window.
4. Select the arrow to the left of **Network adapters** to expand the list.
5. Choose the name, or open the context menu for the **Amazon Elastic Network Adapter**, and then choose **Properties**. This opens the **Amazon Elastic Network Adapter Properties** dialog.
6. Open the **Advanced** tab in the pop-up window.
7. From the **Property** list, choose **Metrics Refresh Interval** to change the value.
8. When you are done, choose **OK**.

EN Adapter reset

The reset process starts when the ENA Windows driver detects an error on an adapter, and marks the adapter as unhealthy. The driver cannot reset itself, so it depends on the operating system to check the adapter health status, and call the reset handle for the ENA Windows driver. The reset process might result in a brief period of time where traffic loss occurs. However, TCP connections should be able to recover.

The EN Adapter might also indirectly request a device reset procedure, by failing to send a keep-alive notification. For example, if the EN Adapter reaches an unknown state after loading an irrecoverable configuration, it might stop sending keep-alive notifications.

Common causes for EN Adapter reset

- Keep-alive messages are missing

The EN Adapter posts keep-alive events at a fixed rate (usually once every second). The ENA Windows driver implements a watchdog mechanism, which periodically checks for the presence of these keep-alive messages. If it detects one or more new messages since the last time it checked, it records a successful outcome. Otherwise, the driver concludes that the device experienced a failure, and initiates a reset sequence.

- Packets are stuck in transmit queues

The EN Adapter verifies that packets are flowing through the transmit queues as expected. The ENA Windows driver detects if packets are getting stuck, and initiates a reset sequence if they are.

- Read timeout for Memory Mapped I/O (MMIO) registers

To limit memory mapped I/O (MMIO) read operations, the ENA Windows driver accesses MMIO registers only during initialization and reset processes. If the driver detects a timeout, it takes one of the following actions, depending on what process was running:

- If a timeout is detected during initialization, it fails the flow, which results in the driver displaying a yellow exclamation mark by the EN Adapter in Windows Device Manager.

- If a timeout is detected during reset, it fails the flow. The OS then initiates a surprise removal of the ENA adapter, and recovers it by stopping and starting the adapter that was removed. For more information about surprise removal of a network interface card (NIC), see [Handling the Surprise Removal of a NIC](#) in the *Microsoft Windows Hardware Developer* documentation.

Troubleshooting scenarios

The following scenarios can help you troubleshoot issues that you might experience with the ENA Windows driver. We recommend that you start with upgrading your ENA driver, if you don't have the latest version. To find the latest driver for your Windows OS version, see [Amazon ENA driver versions \(p. 1333\)](#).

Unexpected ENA driver version installed

Description

After you go through the steps to install a specific version of the ENA driver, the Windows Device Manager shows that Windows installed a different version of the ENA driver.

Cause

When you run the install for a driver package, Windows ranks all of the driver packages that are valid for the given device in the local [Driver Store](#) before it begins. Then it selects the package with the lowest rank value as the best match. This can be different from the package that you intended to install. For more information about the device driver package selection process, see [How Windows selects a driver package for a device](#) on the *Microsoft documentation website*.

Solution

To ensure that Windows installs your chosen driver package version, you can remove lower ranked driver packages from the Driver Store with the [PnPUtility](#) command line tool.

Follow these steps to update the ENA driver:

1. Connect to your instance and log in as the local administrator.
2. Open the Device Manager properties window, as described in the [Check ENA device status \(p. 2151\)](#) section. This opens the **General** tab of the **Amazon Elastic Network Adapter Properties** window.
3. Open the **Driver** tab.
4. Choose **Update Driver**. This opens the **Update Driver Software – Amazon Elastic Network Adapter** dialog box.
 - a. On the **How do you want to search for driver software?** page, choose **Browse my computer for driver software**.
 - b. On the **Browse for driver software on your computer** page, choose **Let me pick from a list of device drivers on my computer**, located below the search bar.
 - c. On the **Select the device driver you want to install for this hardware** page, choose **Have Disk....**
 - d. In the **Install from Disk** window, choose **Browse...**, next to the file location from the dropdown list.
 - e. Navigate to the location where you downloaded the target ENA driver package. Select the file named **ena.inf** and choose **Open**.
 - f. To start the install, choose **OK**, and then choose **Next**.
5. If the installer doesn't automatically reboot your instance, run the **Restart-Computer** PowerShell cmdlet.

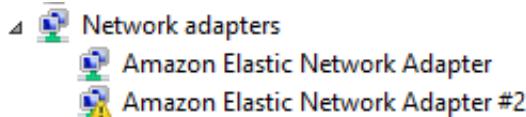

```
PS C:\> Restart-Computer
```

Device warning for ENA driver

Description

The ENA adapter icon in the Device Manager **Network adapters** section displays a warning sign (a yellow triangle with an exclamation mark inside).

The following example shows an ENA adapter with the warning icon in Windows Device Manager:

Cause

This device warning is commonly caused by environment issues, which might require more research, and often require a process of elimination to determine the underlying cause. For a full list of device errors, see [Device Manager Error Messages](#) in the *Microsoft Windows Hardware Developer* documentation.

Solution

The solution for this device warning depends on the root cause. The process of elimination described here includes a few basic steps to help identify and resolve the most common issues that might have a simple solution. Additional root cause analysis is required when these steps do not resolve the issue.

Follow these steps to help identify and resolve common issues:

1. Stop and start the device

Open the Device Manager properties window, as described in the [Check ENA device status \(p. 2151\)](#) section. This opens the **General** tab of the **Amazon Elastic Network Adapter Properties** window, where the **Device status** displays the error code and a short message.

- a. Open the **Driver** tab.
- b. Choose **Disable Device**, and respond **Yes** to the warning message that displays.
- c. Choose **Enable Device**.

2. Stop and start the EC2 instance

If the adapter still shows the warning icon in Device Manager, the next step is to stop and start the EC2 instance. This relaunches the instance on different hardware in most cases.

3. Investigate possible instance resource issue

If you have stopped and started your EC2 instance, and the problem persists, this might indicate a resource issue on your instance, such as insufficient memory.

Connection timeout with adapter reset (error codes 5007, 5205)

Description

The Windows Event Viewer shows adapter timeout and reset events occurring in combination for ENA adapters. Messages resemble the following examples:

- **Event ID 5007:** Amazon Elastic Network Adapter : Timed out during an operation.
- **Event ID 5205:** Amazon Elastic Network Adapter : Adapter reset has been started.

Adapter resets cause minimal traffic disruption. Even when there are multiple resets, it would be unusual for them to cause any severe network disruption.

Cause

This sequence of events indicates that the ENA Windows driver initiated a reset for an ENA adapter that was unresponsive. However, the mechanism that the device driver uses to detect this issue is subject to false positives resulting from CPU 0 starvation.

Solution

If this combination of errors happens frequently, check your resource allocations to see where adjustments might be helpful.

1. Open the **Run** dialog using one of the methods described in the preceding section.
2. To open the Windows Resource Monitor, enter `resmon` in the **Run** box.
3. Choose **OK**. This opens the Resource Monitor window.
4. Open the **CPU** tab. Per-CPU usage graphs are shown along the right side of the Resource Monitor window.
5. Check the usage levels for CPU 0 to see if they are too high.

We recommend that you configure RSS to exclude CPU 0 for the ENA adapter on larger instance types (more than 16 vCPU). For smaller instance types, configuring RSS might improve the experience, but due to the lower number of available cores, testing is necessary to ensure that constraining CPU cores does not negatively impact performance.

Use the **Set-NetAdapterRss** command to configure RSS for your ENA adapter, as shown in the following example.

```
Set-NetAdapterRss -name (Get-NetAdapter | Where-Object {$_.InterfaceDescription -like "*Elastic*"}).Name -Baseprocessorgroup 0 -BaseProcessorNumber 1
```

Migrating to a sixth generation instance infrastructure impacts performance or attachment

Description

If you migrate to a sixth generation EC2 instance, you might experience reduced performance or ENA attachment failures if you haven't updated your ENA Windows driver version.

Cause

Windows requires driver version 2.2.3 or later. However, driver version 2.2.4 can also cause performance degradation on sixth generation instances, and has been rolled back. For more information, see the article [What do I need to do before migrating my EC2 instance to a sixth generation instance to make sure that I get maximum network performance?](#) in the AWS Knowledge Center.

Solution

Prior to upgrading to sixth generation EC2 instances, make sure that the AMI that you use to launch the instances has compatible drivers (v2.2.3 or later). For more information about ensuring that you

have required drivers for sixth generation instances, see [What do I need to do before migrating my EC2 instance to a sixth generation instance to make sure that I get maximum network performance?](#)

Note

Driver version 2.2.4 rollback

ENA Windows driver version 2.2.4 has been rolled back due to potential performance degradation on the sixth generation EC2 instances. If driver version 2.2.4 is installed, we recommend that you downgrade the driver, using one of the following methods:

- **Install the previous version**

1. Download the previous version package from the [Amazon ENA driver versions \(p. 1333\)](#) table (version 2.2.3).
2. Run the `install.ps1` PowerShell installation script.

For more details for pre- and post-installation steps see [Enable enhanced networking on Windows \(p. 1329\)](#).

Use Amazon EC2 Systems Manager for a bulk update

- Perform a bulk update via SSM document AWS-ConfigureAWSPackage, with the following parameters:
 - **Name:** AwsEnaNetworkDriver
 - **Version:** 2.2.3

Suboptimal performance for the elastic network interface

Description

The ENA interface is not performing as expected.

Cause

Root cause analysis for performance issues is a process of elimination. There are too many variables involved to name a common cause.

Solution

The first step in your root cause analysis is to review the diagnostic information for the instance that is not performing as expected, to determine if there are errors that might be causing the issue. For more information, see the [Collect diagnostic information on the instance \(p. 2150\)](#) section.

You might need to modify the default operating system configuration to achieve maximum network performance on instances with enhanced networking. Some optimizations, such as turning on checksum offloading and enabling RSS, are configured by default in official Windows AMIs. For other optimizations that you can apply to the ENA adapter, see the performance adjustments shown in [ENA adapter performance adjustments \(p. 2158\)](#).

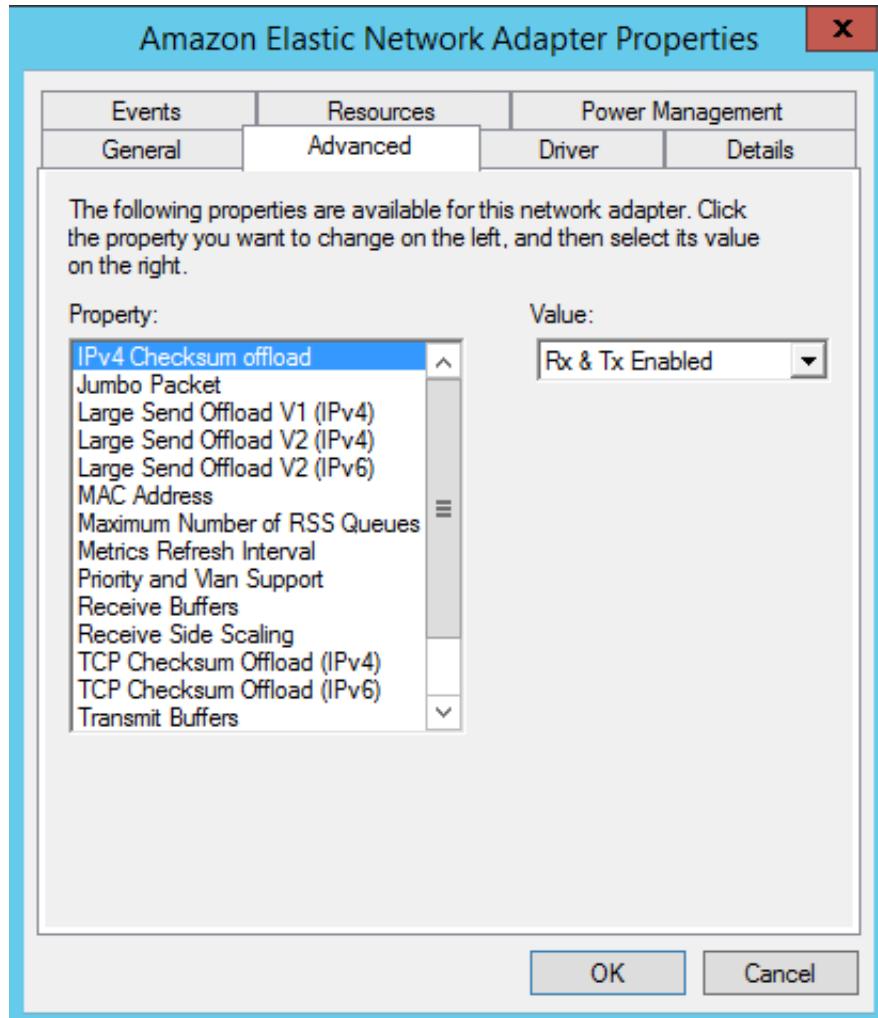

We recommend that you proceed with caution, and limit device property adjustments to those that are listed in this section, or to specific changes that are recommended by the AWS support team.

To change ENA adapter properties, follow these steps:

1. Open the **Run** dialog using one of the methods described in the preceding section.
2. To open the Windows Device Manager, enter `devmgmt.msc` in the **Run** box.

3. Choose **OK**. This opens the Device Manager window.
4. Select the arrow to the left of **Network adapters** to expand the list.
5. Choose the name, or open the context menu for the **Amazon Elastic Network Adapter**, and then choose **Properties**. This opens the **Amazon Elastic Network Adapter Properties** dialog.
6. To make your changes, open the **Advanced** tab.
7. When you're done, choose **OK** to save your changes.

The following example shows an ENA adapter property in the Windows Device Manager:

ENA adapter performance adjustments

The following table includes properties that can be adjusted to improve performance for the ENA interface.

Input

Property	Description	Default value	Adjustment
Receive Buffers	Controls the number of entries in the software receive queues.	1024	Can be increased up to a maximum of 8192.

Property	Description	Default value	Adjustment
Receive Side Scaling (RSS)	Enables the efficient distribution of network receive processing across multiple CPUs in multiprocessor systems.	Enabled	You can spread the load across multiple processors. To learn more, see Operating system optimizations (p. 1348) .
Maximum Number of RSS Queues	Sets the maximum number of RSS queues allowed when RSS is enabled.	32	The number of RSS queues is determined during driver initialization, and includes the following limitations (among others): <ul style="list-style-type: none"> • RSS queue limit set by this property • Instance limits (vCPU count) • Hardware generation limits (up to 8 RSS queues in ENAv1, and up to 32 RSS queues in ENAv2) You can set the value from 1-32, depending on your instance and hardware generation limits. To learn more, see Operating system optimizations (p. 1348) .
Jumbo packet	Enables the use of jumbo ethernet frames (more than 1500 bytes of payload).	Disabled (this limits payload to 1500 bytes or less)	Value can be set up to 9015, which translates to 9001 bytes of payload. This is the maximum payload for jumbo ethernet frames. See Considerations for using jumbo ethernet frames (p. 2159) .

Considerations for using jumbo ethernet frames

Jumbo frames allow more than 1500 bytes of data by increasing the payload size per packet, which increases the percentage of the packet that is not packet overhead. Fewer packets are needed to send the same amount of usable data. However, traffic is limited to a maximum MTU of 1500 in the following cases:

- Traffic outside of a given AWS Region for EC2 Classic.
- Traffic outside of a single VPC.
- Traffic over an inter-Region VPC peering connection.

- Traffic over VPN connections.
- Traffic over an internet gateway.

Note

Packets over 1500 bytes are fragmented. If you have the Don't Fragment flag set in the IP header, these packets are dropped.

Jumbo frames should be used with caution for internet-bound traffic, or any traffic that leaves a VPC. Packets are fragmented by intermediate systems, which slows down this traffic. To use jumbo frames inside of a VPC without impacting outbound traffic that's leaving the VPC, try one of the following options:

- Configure the MTU size by route.
- Use multiple network interfaces with different MTU sizes and different routes.

Recommended use cases for jumbo frames

Jumbo frames can be useful for traffic inside of and between VPCs. We recommend using jumbo frames for the following use cases:

- For instances that are collocated inside of a cluster placement group, jumbo frames help to achieve the maximum network throughput possible. For more information, see [Placement groups \(p. 1352\)](#).
- You can use jumbo frames for traffic between your VPCs and your on-premises networks over AWS Direct Connect. For more information about using AWS Direct Connect, and verifying jumbo frame capability, see [Set network MTU for private virtual interfaces or transit virtual interfaces](#) in the [AWS Direct Connect User Guide](#).
- For more information about supported MTU sizes for transit gateways, see [Quotas for your transit gateways](#) in the [Amazon VPC Transit Gateways](#).

Use EC2Rescue for Windows Server

EC2Rescue for Windows Server is an easy-to-use tool that you run on an Amazon EC2 Windows Server instance to diagnose and troubleshoot possible problems. It is valuable for collecting log files and troubleshooting issues and also proactively searching for possible areas of concern. It can even examine Amazon EBS root volumes from other instances and collect relevant logs for troubleshooting Windows Server instances using that volume.

EC2Rescue for Windows Server has two different modules: a data collector module that collects data from all different sources, and an analyzer module that parses the data collected against a series of predefined rules to identify issues and provide suggestions.

The EC2Rescue for Windows Server tool only runs on Amazon EC2 instances running Windows Server 2008 R2 and later. When the tool starts, it checks whether it is running on an Amazon EC2 instance.

The AWSSupport-ExecuteEC2Rescue runbook uses the EC2Rescue tool to troubleshoot and, where possible, fix common connectivity issues with the specified EC2 instance. For more information, and to run this automation, see [AWSSupport-ExecuteEC2Rescue](#).

Note

If you are using a Linux instance, see [EC2Rescue for Linux](#).

Contents

- [Use EC2Rescue for Windows Server GUI \(p. 2161\)](#)
- [Use EC2Rescue for Windows Server with the command line \(p. 2164\)](#)

Use EC2Rescue for Windows Server GUI

EC2Rescue for Windows Server can perform the following analysis on **offline instances**:

Option	Description
Diagnose and Rescue	<p>EC2Rescue for Windows Server can detect and address issues with the following service settings:</p> <ul style="list-style-type: none">• System Time<ul style="list-style-type: none">• RealTimeisUniversal - Detects whether the RealTimeisUniversal registry key is enabled. If disabled, Windows system time drifts when the timezone is set to a value other than UTC.• Windows Firewall<ul style="list-style-type: none">• Domain networks - Detects whether this Windows Firewall profile is enabled or disabled.• Private networks - Detects whether this Windows Firewall profile is enabled or disabled.• Guest or public networks - Detects whether this Windows Firewall profile is enabled or disabled.• Remote Desktop<ul style="list-style-type: none">• Service Start - Detects whether the Remote Desktop service is enabled.• Remote Desktop Connections - Detects whether this is enabled.• TCP Port - Detects which port the Remote Desktop service is listening on.• EC2Config (Windows Server 2012 R2 and earlier)<ul style="list-style-type: none">• Installation - Detects which EC2Config version is installed.• Service Start - Detects whether the EC2Config service is enabled.• Ec2SetPassword - Generates a new administrator password.• Ec2HandleUserData - Allows you to run a user data script on the next boot of the instance.• EC2Launch (Windows Server 2016 and later)<ul style="list-style-type: none">• Installation - Detects which EC2Launch version is installed.

Option	Description
	<ul style="list-style-type: none"> • Ec2SetPassword - Generates a new administrator password. • Network Interface <ul style="list-style-type: none"> • DHCP Service Startup - Detects whether the DHCP service is enabled. • Ethernet detail - Displays information about the network driver version, if detected. • DHCP on Ethernet - Detects whether DHCP is enabled. • Disk signature status <ul style="list-style-type: none"> • Signature on disk and Signature on Boot Configuration Database (BCD) - Detects whether the disk signature and the BCD signature are the same. If the values are different, EC2Rescue attempts to overwrite the disk signature with the signature on BCD.
Restore	<p>Perform one of the following actions:</p> <ul style="list-style-type: none"> • Last Known Good Configuration - Attempts to boot the instance into the last known bootable state. • Restore registry from backup - Restores the registry from <code>\Windows\System32\config\RegBack</code>.
Capture Logs	Allows you to capture logs on the instance for analysis.

EC2Rescue for Windows Server can collect the following data from **active and offline instances**:

Item	Description
Event Log	Collects application, system, and EC2Config event logs.
Registry	Collects SYSTEM and SOFTWARE hives.
Windows Update Log	Collects log files generated by Windows Update. Note In Windows Server 2016 and later, the log is collected in Event Tracing for Windows (ETW) format.
Sysprep Log	Collects log files generated by the Windows System Preparation tool.
Driver Setup Log	Collects Windows SetupAPI logs (<code>setupapi.dev.log</code> and <code>setupapi.setup.log</code>).

Item	Description
Boot Configuration	Collects HKEY_LOCAL_MACHINE\BCD00000000 hive.
Memory Dump	Collects any memory dump files that exist on the instance.
EC2Config File	Collects log files generated by the EC2Config service.
EC2Launch File	Collects log files generated by the EC2Launch scripts.
SSM Agent File	Collects log files generated by SSM Agent and Patch Manager logs.
EC2 ElasticGPUs File	Collects event logs related to elastic GPUs.
ECS	Collects logs related to Amazon ECS.
CloudEndure	Collects log files related to CloudEndure Agent.

EC2Rescue for Windows Server can collect the following additional data from **active instances**:

Item	Description
System Information	Collects MSInfo32.
Group Policy Result	Collects a Group Policy report.

Analyze an offline instance

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](#).

The **Offline Instance** option is useful for debugging boot issues with Windows instances.

To perform an action on an offline instance

- From a working Windows Server instance, download the [EC2Rescue for Windows Server](#) tool and extract the files.

You can run the following PowerShell command to download EC2Rescue without changing your Internet Explorer Enhanced Security Configuration (ESC):

```
Invoke-WebRequest https://s3.amazonaws.com/ec2rescue/windows/EC2Rescue_latest.zip -  
OutFile $env:USERPROFILE\Desktop\EC2Rescue_latest.zip
```

This command will download the EC2Rescue .zip file to the desktop of the currently logged in user.

- Stop the faulty instance, if it is not stopped already.
- Detach the EBS root volume from the faulty instance and attach the volume to a working Windows instance that has EC2Rescue for Windows Server installed.

4. Run the EC2Rescue for Windows Server tool on the working instance and choose **Offline Instance**.
5. Select the disk of the newly mounted volume and choose **Next**.
6. Confirm the disk selection and choose **Yes**.
7. Choose the offline instance option to perform and choose **Next**.

The EC2Rescue for Windows Server tool scans the volume and collects troubleshooting information based on the selected log files.

Collect data from an active instance

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](#).

You can collect logs and other data from an active instance.

To collect data from an active instance

1. Connect to your Windows instance.
2. Download the [EC2Rescue for Windows Server](#) tool to your Windows instance and extract the files.

You can run the following PowerShell command to download EC2Rescue without changing your Internet Explorer Enhanced Security Configuration (ESC):

```
Invoke-WebRequest https://s3.amazonaws.com/ec2rescue/windows/  
EC2Rescue_latest.zip -OutFile $env:USERPROFILE\Desktop\EC2Rescue_latest.zip
```

This command will download the EC2Rescue .zip file to the desktop of the currently logged in user.

3. Open the EC2Rescue for Windows Server application and accept the license agreement.
4. Choose **Next, Current instance, Capture logs**.
5. Select the data items to collect and choose **Collect....** Read the warning and choose **Yes** to continue.
6. Choose a file name and location for the ZIP file and choose **Save**.
7. After EC2Rescue for Windows Server completes, choose **Open Containing Folder** to view the ZIP file.
8. Choose **Finish**.

Use EC2Rescue for Windows Server with the command line

The EC2Rescue for Windows Server command line interface (CLI) allows you to run an EC2Rescue for Windows Server plugin (referred as an "action") programmatically.

The EC2Rescue for Windows Server tool has two execution modes:

- **/online**—This allows you to take action on the instance that EC2Rescue for Windows Server is installed on, such as collect log files.
- **/offline:<device_id>**—This allows you to take action on the offline root volume that is attached to a separate Amazon EC2 Windows instance, on which you have installed EC2Rescue for Windows Server.

Download the [EC2Rescue for Windows Server](#) tool to your Windows instance and extract the files. You can view the help file using the following command:

```
EC2RescueCmd.exe /help
```

EC2Rescue for Windows Server can perform the following actions on an Amazon EC2 Windows instance:

- [Collect action \(p. 2165\)](#)
- [Rescue action \(p. 2167\)](#)
- [Restore action \(p. 2169\)](#)

Collect action

Note

You can collect all logs, an entire log group, or an individual log within a group.

EC2Rescue for Windows Server can collect the following data from **active and offline instances**.

Log group	Available logs	Description
all		Collects all available logs.
eventlog	<ul style="list-style-type: none">'Application''System''EC2ConfigService'	Collects application, system, and EC2Config event logs.
memory-dump	<ul style="list-style-type: none">'Memory Dump File''Mini Dump Files'	Collects any memory dump files that exist on the instance.
ec2config	<ul style="list-style-type: none">'Log Files''Configuration Files'	Collects log files generated by the EC2Config service.
ec2launch	<ul style="list-style-type: none">'Logs''Config'	Collects log files generated by the EC2Launch scripts.
ssm-agent	<ul style="list-style-type: none">'Log Files''Patch Baseline Logs''InstanceIdata'	Collects log files generated by SSM Agent and Patch Manager logs.
sysprep	'Log Files'	Collects log files generated by the Windows System Preparation tool.
driver-setup	<ul style="list-style-type: none">'SetupAPI Log Files''DPIInst Log File''AWS PV Setup Log File'	Collects Windows SetupAPI logs (setupapi.dev.log and setupapi.setup.log).
registry	<ul style="list-style-type: none">'SYSTEM''SOFTWARE''BCD'	Collects SYSTEM and SOFTWARE hives.
egpu	<ul style="list-style-type: none">'Event Log'	Collects event logs related to elastic GPUs.

Log group	Available logs	Description
	• 'System Files'	
boot-config	'BCDEDIT Output'	Collects HKEY_LOCAL_MACHINE \BCD00000000 hive.
windows-update	'Log Files'	Collects log files generated by Windows Update. Note In Windows Server 2016 and later, the log is collected in Event Tracing for Windows (ETW) format.
cloudendure	• 'Migrate Script Logs' • 'Driver Logs' • 'CloudEndure File List'	Collects log files related to CloudEndure Agent.

EC2Rescue for Windows Server can collect the following additional data from **active instances**.

Log group	Available logs	Description
system-info	'MSInfo32 Output'	Collects MSInfo32.
gpresult	'GPResult Output'	Collects a Group Policy report.

The following are the available options:

- **/output:<outputFilePath>** - Required destination file path location to save collected log files in zip format.
- **/no-offline** - Optional attribute used in offline mode. Does not set the volume offline after completing the action.
- **/no-fix-signature** - Optional attribute used in offline mode. Does not fix a possible disk signature collision after completing the action.

Examples

The following are examples using the EC2Rescue for Windows Server CLI.

Online mode examples

Collect all available logs:

```
EC2RescueCmd /accepteula /online /collect:all /output:<outputFilePath>
```

Collect only a specific log group:

```
EC2RescueCmd /accepteula /online /collect:ec2config /output:<outputFilePath>
```

Collect individual logs within a log group:

```
EC2RescueCmd /accepteula /online /collect:'ec2config.Log Files,driver-setup.SetupAPI Log Files' /output:<outputFilePath>
```

Offline mode examples

Collect all available logs from an EBS volume. The volume is specified by the device_id value.

```
EC2RescueCmd /accepteula /offline:xvdf /collect:all /output:<outputFilePath>
```

Collect only a specific log group:

```
EC2RescueCmd /accepteula /offline:xvdf /collect:ec2config /output:<outputFilePath>
```

Rescue action

EC2Rescue for Windows Server can detect and address issues with the following service settings:

Service group	Available actions	Description
all		
system-time	'RealTimeIsUniversal'	<p>System Time</p> <ul style="list-style-type: none">RealTimeisUniversal - Detects whether the RealTimeisUniversal registry key is enabled. If disabled, Windows system time drifts when the timezone is set to a value other than UTC.
firewall	<ul style="list-style-type: none">'Domain networks''Private networks''Guest or public networks'	<p>Windows Firewall</p> <ul style="list-style-type: none">Domain networks - Detects whether this Windows Firewall profile is enabled or disabled.Private networks - Detects whether this Windows Firewall profile is enabled or disabled.Guest or public networks - Detects whether this Windows Firewall profile is enabled or disabled.
rdp	<ul style="list-style-type: none">'Service Start''Remote Desktop Connections''TCP Port'	<p>Remote Desktop</p> <ul style="list-style-type: none">Service Start - Detects whether the Remote Desktop service is enabled.Remote Desktop Connections - Detects whether this is enabled.

Service group	Available actions	Description
		<ul style="list-style-type: none"> • TCP Port - Detects which port the Remote Desktop service is listening on.
ec2config	<ul style="list-style-type: none"> • 'Service Start' • 'Ec2SetPassword' • 'Ec2HandleUserData' 	EC2Config <ul style="list-style-type: none"> • Service Start - Detects whether the EC2Config service is enabled. • Ec2SetPassword - Generates a new administrator password. • Ec2HandleUserData - Allows you to run a user data script on the next boot of the instance.
ec2launch	'Reset Administrator Password'	Generates a new Windows administrator password.
network	'DHCP Service Startup'	Network Interface <ul style="list-style-type: none"> • DHCP Service Startup - Detects whether the DHCP service is enabled.

The following are the available options:

- **/level:<level>** - Optional attribute for the check level that the action should trigger. Allowed values are: information, warning, error, all. By default, it is set to error.
- **/check-only** - Optional attribute that generates a report but makes no modifications to the offline volume.
- **/no-offline** - Optional attribute that prevents the volume from being set offline after completing the action.
- **/no-fix-signature** - Optional attribute that does not fix a possible disk signature collision after completing the action.

Rescue examples

The following are examples using the EC2Rescue for Windows Server CLI. The volume is specified using the device_id value.

Attempt to fix all identified issues on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /rescue:all
```

Attempt to fix all issues within a service group on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /rescue:firewall
```

Attempt to fix a specific item within a service group on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /rescue:rdp.'Service Start'
```

Specify multiple issues to attempt to fix on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /rescue:'system-time.RealTimeIsUniversal,ec2config.Service Start'
```

Restore action

EC2Rescue for Windows Server can detect and address issues with the following service settings:

Service Group	Available Actions	Description
Restore Last Known Good Configuration	lkgc	Last Known Good Configuration - Attempts to boot the instance into the last known bootable state.
Restore Windows registry from latest backup	regback	Restore registry from backup - Restores the registry from \Windows\System32\config\RegBack.

The following are the available options:

- **/no-offline**—Optional attribute that prevents the volume from being set offline after completing the action.
- **/no-fix-signature**—Optional attribute that does not fix a possible disk signature collision after completing the action.

Restore examples

The following are examples using the EC2Rescue for Windows Server CLI. The volume is specified using the device_id value.

Restore last known good configuration on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /restore:lkgc
```

Restore the last Windows registry backup on a volume:

```
EC2RescueCmd /accepteula /offline:xvdf /restore:regback
```

Use EC2Rescue for Windows Server with Systems Manager Run Command

AWS Support provides you with a Systems Manager Run Command document to interface with your Systems Manager-enabled instance to run EC2Rescue for Windows Server. The Run Command document is called AWSSupport-RunEC2RescueForWindowsTool.

This Systems Manager Run Command document performs the following tasks:

- Downloads and verifies EC2Rescue for Windows Server.
- Imports a PowerShell module to ease your interaction with the tool.

- Runs EC2RescueCmd with the provided command and parameters.

The Systems Manager Run Command document accepts three parameters:

- **Command**—The EC2Rescue for Windows Server action. The current allowed values are:
 - **ResetAccess**—Resets the local Administrator password. The local Administrator password of the current instance will be reset and the randomly generated password will be securely stored in Parameter Store as /EC2Rescue/Password/<INSTANCE_ID>. If you select this action and provide no parameters, passwords are encrypted automatically with the default KMS key. Optionally, you can specify a KMS key ID in Parameters to encrypt the password with your own key.
 - **CollectLogs**—Runs EC2Rescue for Windows Server with the /collect:all action. If you select this action, Parameters must include an Amazon S3 bucket name to upload the logs to.
 - **FixAll**—Runs EC2Rescue for Windows Server with the /rescue:all action. If you select this action, Parameters must include the block device name to rescue.
- **Parameters**—The PowerShell parameters to pass for the specified command.

Note

In order for the **ResetAccess** action to work, your Amazon EC2 instance needs to have the following policy attached in order to write the encrypted password to Parameter Store. Please wait a few minutes before attempting to reset the password of an instance after you have attached this policy to the related IAM role.

Using the default KMS key:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ssm:PutParameter"  
            ],  
            "Resource": [  
                "arn:aws:ssm:region:account_id:parameter/EC2Rescue/Passwords/<instanceid>"  
            ]  
        }  
    ]  
}
```

Using a custom KMS key:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ssm:PutParameter"  
            ],  
            "Resource": [  
                "arn:aws:ssm:region:account_id:parameter/EC2Rescue/Passwords/<instanceid>"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "kms:Encrypt"  
            ],  
            "Resource": [  
                "arn:aws:kms:region:account_id:key/key_id"  
            ]  
        }  
    ]  
}
```

```
        "arn:aws:kms:region:account_id:key/<kmskeyid>"  
    }  
}  
}
```

The following procedure describes how to view the JSON for this document in the Amazon EC2 console.

To view the JSON for the Systems Manager Run Command document

1. Open the Systems Manager console at <https://console.aws.amazon.com/systems-manager/home>.
2. In the navigation pane, expand **Shared Services** and choose **Documents**.
3. In the search bar, set **Owner** as **Owned by Me or Amazon** and set the **Document name prefix** to AWSSupport-RunEC2RescueForWindowsTool.
4. Select the AWSSupport-RunEC2RescueForWindowsTool document, choose **Contents**, and then view the JSON.

Examples

Here are some examples on how to use the Systems Manager Run Command document to run EC2Rescue for Windows Server, using the AWS CLI. For more information about sending commands with the AWS CLI, see the [AWS CLI Command Reference](#).

Attempt to fix all identified issues on an offline root volume

Attempt to fix all identified issues on an offline root volume attached to an Amazon EC2 Windows instance:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-RunEC2RescueForWindowsTool" --comment "EC2Rescue offline volume xvdf" --parameters "Command=FixAll, Parameters='xvdf'" --output text
```

Collect logs from the current Amazon EC2 Windows instance

Collect all logs from the current online Amazon EC2 Windows instance and upload them to an Amazon S3 bucket:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-RunEC2RescueForWindowsTool" --comment "EC2Rescue online log collection to S3" --parameters "Command=CollectLogs, Parameters='YOURS3BUCKETNAME'" --output text
```

Collect logs from an offline Amazon EC2 Windows instance volume

Collect all logs from an offline volume attached to an Amazon EC2 Windows instance and upload them to Amazon S3 with a presigned URL:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-RunEC2RescueForWindowsTool" --comment "EC2Rescue offline log collection to S3" --parameters "Command=CollectLogs, Parameters='-\Offline -BlockDeviceName xvdf -S3PreSignedUrl 'YOURS3PRESIGNEDURL'" --output text
```

Reset the local Administrator password

The following examples show methods you can use to reset the local Administrator password. The output provides a link to Parameter Store, where you can find the randomly generated secure password you can then use to RDP to your Amazon EC2 Windows instance as the local Administrator.

Reset the local Administrator password of an online instance using the default AWS KMS key alias/aws/ssm:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-RunEC2RescueForWindowsTool" --comment "EC2Rescue online password reset" --parameters "Command=ResetAccess" --output text
```

Reset the local Administrator password of an online instance using a KMS key:

```
aws ssm send-command --instance-ids "i-0cb2b964d3e14fd9f" --document-name "AWSSupport-RunEC2RescueForWindowsTool" --comment "EC2Rescue online password reset" --parameters "Command=ResetAccess, Parameters=a133dc3c-a2g4-4fc6-a873-6c0720104bf0" --output text
```

Note

In this example, the KMS key is a133dc3c-a2g4-4fc6-a873-6c0720104bf0.

EC2 Serial Console for Windows instances

With the EC2 serial console, you have access to your Amazon EC2 instance's serial port, which you can use to troubleshoot boot, network configuration, and other issues. The serial console does not require your instance to have any networking capabilities. With the serial console, you can enter commands to an instance as if your keyboard and monitor are directly attached to the instance's serial port. The serial console session lasts during instance reboot and stop. During reboot, you can view all of the boot messages from the start.

Access to the serial console is not available by default. Your organization must grant account access to the serial console and configure IAM policies to grant your users access to the serial console. Serial console access can be controlled at a granular level by using instance IDs, resource tags, and other IAM levers. For more information, see [Configure access to the EC2 Serial Console \(p. 2175\)](#).

The serial console can be accessed by using the EC2 console or the AWS CLI.

The serial console is available at no additional cost.

If you are using a Linux instance, see [EC2 Serial Console for Linux instances](#) in the *Amazon EC2 User Guide for Linux Instances*.

Topics

- [Prerequisites \(p. 2172\)](#)
- [Configure access to the EC2 Serial Console \(p. 2175\)](#)
- [Connect to the EC2 Serial Console \(p. 2180\)](#)
- [Disconnect from the EC2 Serial Console \(p. 2184\)](#)
- [Troubleshoot your Windows instance using the EC2 Serial Console \(p. 2184\)](#)

Prerequisites

To connect to the EC2 Serial Console and use your chosen tool for troubleshooting, the following prerequisites must be in place:

- [AWS Regions \(p. 2173\)](#)
- [Wavelength Zones and AWS Outposts \(p. 2173\)](#)
- [Local Zones \(p. 2173\)](#)
- [Instance types \(p. 2173\)](#)
- [Grant access \(p. 2173\)](#)

- [Support for browser-based client \(p. 2173\)](#)
- [Instance state \(p. 2174\)](#)
- [Amazon EC2 Systems Manager \(p. 2174\)](#)
- [sshd server \(p. 2174\)](#)
- [Configure your chosen troubleshooting tool \(p. 2174\)](#)

AWS Regions

Supported in the following AWS Regions:

- US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon)
- Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Paris), Europe (Stockholm)
- South America (São Paulo)
- AWS GovCloud (US-East), AWS GovCloud (US-West)

Wavelength Zones and AWS Outposts

Not supported.

Local Zones

Supported in the following Local Zones:

- Dallas, US

Local Zone name: us-east-1-dfw-1a

Parent Region: US East (N. Virginia)

- Los Angeles, US

Local Zone names: us-west-2-lax-1a, us-west-2-lax-1b

Parent Region: US West (Oregon)

Instance types

Supported for all virtualized instances built on the [Nitro System \(p. 219\)](#).

Not supported on bare metal instances.

Grant access

You must complete the configuration tasks to grant access to the EC2 Serial Console. For more information, see [Configure access to the EC2 Serial Console \(p. 2175\)](#).

Support for browser-based client

To connect to the serial console [using the browser-based client \(p. 2180\)](#), your browser must support WebSocket. If your browser does not support WebSocket, connect to the serial console [using your own key and an SSH client \(p. 2181\)](#)

Instance state

Must be running.

You can't connect to the serial console if the instance is in the pending, stopping, stopped, shutting-down, or terminated state.

For more information about the instance states, see [Instance lifecycle \(p. 546\)](#).

Amazon EC2 Systems Manager

If the instance uses Amazon EC2 Systems Manager, then SSM Agent version 3.0.854.0 or later must be installed on the instance. For information about SSM Agent, see [Working with SSM Agent](#) in the *AWS Systems Manager User Guide*.

sshd server

You do not need an sshd server installed or running on your instance.

Configure your chosen troubleshooting tool

To troubleshoot your Windows instance via the serial console, you can use the Special Admin Console (SAC). Before you can use SAC, you must first enable SAC and the boot menu on every instance on which you'll use it.

For the instructions to configure your chosen troubleshooting tool on Linux, see [Configure your chosen troubleshooting tool](#) in the *Amazon EC2 User Guide for Linux Instances*.

Enable SAC and the boot menu

Note

If you enable SAC on an instance, the EC2 services that rely on password retrieval will not work from the Amazon EC2 console. Windows on Amazon EC2 launch agents (EC2Config, EC2Launch v1, and EC2Launch v2) rely on the serial console to execute various tasks. These tasks do not perform successfully when you enable SAC on an instance. For more information about Windows on Amazon EC2 launch agents, see [Configure your Windows instance](#). If you enable SAC, you can disable it later. For more information, see [Disable SAC and the boot menu \(p. 2188\)](#).

Use one of the following methods to enable SAC and the boot menu on an instance.

PowerShell

To enable SAC and the boot menu on a Windows instance

1. [Connect \(p. 626\)](#) to your instance and perform the following steps from an elevated PowerShell command line.
2. Enable SAC.

```
bcdedit /ems '{current}' on  
bcdedit /emssettings EMSPORT:1 EMSBAUDRATE:115200
```

3. Enable the boot menu.

```
bcdedit /set '{bootmgr}' displaybootmenu yes  
bcdedit /set '{bootmgr}' timeout 15  
bcdedit /set '{bootmgr}' bootevals yes
```

4. Apply the updated configuration by rebooting the instance.

```
shutdown -r -t 0
```

Command prompt

To enable SAC and the boot menu on a Windows instance

1. [Connect \(p. 626\)](#) to your instance and perform the following steps from the command prompt.
2. Enable SAC.

```
bcdedit /ems {current} on  
bcdedit /emssettings EMSPORT:1 EMSBAUDRATE:115200
```

3. Enable the boot menu.

```
bcdedit /set {bootmgr} displaybootmenu yes  
bcdedit /set {bootmgr} timeout 15  
bcdedit /set {bootmgr} bootevals yes
```

4. Apply the updated configuration by rebooting the instance.

```
shutdown -r -t 0
```

Configure access to the EC2 Serial Console

To configure access to the serial console, you must grant serial console access at the account level and then configure IAM policies to grant access to your users.

Before commencing, be sure to check the [prerequisites \(p. 2172\)](#).

Topics

- [Levels of access to the EC2 Serial Console \(p. 2175\)](#)
- [Manage account access to the EC2 Serial Console \(p. 2176\)](#)
- [Configure IAM policies for EC2 Serial Console access \(p. 2178\)](#)

Levels of access to the EC2 Serial Console

By default, there is no access to the serial console at the account level. You need to explicitly grant access to the serial console at the account level. For more information, see [Manage account access to the EC2 Serial Console \(p. 2176\)](#).

You can use a service control policy (SCP) to allow access to the serial console within your organization. You can then have granular access control at the user level by using an IAM policy to control access. By using a combination of SCP and IAM policies, you have different levels of access control to the serial console.

Organization level

You can use a service control policy (SCP) to allow access to the serial console for member accounts within your organization. For more information about SCPs, see [Service control policies](#) in the [AWS Organizations User Guide](#).

Instance level

You can configure the serial console access policies by using IAM PrincipalTag and ResourceTag constructions and by specifying instances by their ID. For more information, see [Configure IAM policies for EC2 Serial Console access \(p. 2178\)](#).

User level

You can configure access at the user level by configuring an IAM policy to allow or deny a specified user the permission to push the SSH public key to the serial console service of a particular instance. For more information, see [Configure IAM policies for EC2 Serial Console access \(p. 2178\)](#).

Manage account access to the EC2 Serial Console

By default, there is no access to the serial console at the account level. You need to explicitly grant access to the serial console at the account level.

Topics

- [Grant permission to users to manage account access \(p. 2176\)](#)
- [View account access status to the serial console \(p. 2176\)](#)
- [Grant account access to the serial console \(p. 2177\)](#)
- [Deny account access to the serial console \(p. 2177\)](#)

Grant permission to users to manage account access

To allow your users to manage account access to the EC2 serial console, you need to grant them the required IAM permissions.

The following policy grants permissions to view the account status, and to allow and prevent account access to the EC2 serial console.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ec2:GetSerialConsoleAccessStatus",  
                "ec2:EnableSerialConsoleAccess",  
                "ec2:DisableSerialConsoleAccess"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

For more information, see [Creating IAM policies](#) in the *IAM User Guide*.

View account access status to the serial console

To view account access status to the serial console (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the left navigation pane, choose **EC2 Dashboard**.
3. From **Account attributes**, choose **EC2 Serial Console**.

The **EC2 Serial Console access** field indicates whether account access is **Allowed** or **Prevented**.

The following screenshot shows that the account is prevented from using the EC2 serial console.

A screenshot of the AWS EC2 Serial Console settings page. The top navigation bar includes 'EC2 > Settings' and tabs for 'EBS encryption', 'Zones', 'Default credit specification', 'EC2 Serial Console' (which is highlighted in orange), and 'Console experiments'. Below the tabs, there's a section titled 'EC2 Serial Console' with a 'Info' link. It says 'Allow or prevent access to your EC2 instances via the EC2 Serial Console for your account.' There are two buttons: a 'Manage' button with a circular arrow icon and a 'Prevented' button with a crossed-out circle icon. The 'Prevented' button is highlighted with a red border.

To view account access status to the serial console (AWS CLI)

Use the [get-serial-console-access-status](#) command to view account access status to the serial console.

```
aws ec2 get-serial-console-access-status --region us-east-1
```

In the following output, true indicates that the account is allowed access to the serial console.

```
{  
    "SerialConsoleAccessEnabled": true  
}
```

Grant account access to the serial console

To grant account access to the serial console (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the left navigation pane, choose **EC2 Dashboard**.
3. From **Account attributes**, choose **EC2 Serial Console**.
4. Choose **Manage**.
5. To allow access to the EC2 serial console of all instances in the account, select the **Allow** check box.
6. Choose **Update**.

To grant account access to the serial console (AWS CLI)

Use the [enable-serial-console-access](#) command to allow account access to the serial console.

```
aws ec2 enable-serial-console-access --region us-east-1
```

In the following output, true indicates that the account is allowed access to the serial console.

```
{  
    "SerialConsoleAccessEnabled": true  
}
```

Deny account access to the serial console

To deny account access to the serial console (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. On the left navigation pane, choose **EC2 Dashboard**.
3. From **Account attributes**, choose **EC2 Serial Console**.
4. Choose **Manage**.
5. To prevent access to the EC2 serial console of all instances in the account, clear the **Allow** check box.
6. Choose **Update**.

To deny account access to the serial console (AWS CLI)

Use the [disable-serial-console-access](#) command to prevent account access to the serial console.

```
aws ec2 disable-serial-console-access --region us-east-1
```

In the following output, false indicates that the account is denied access to the serial console.

```
{  
    "SerialConsoleAccessEnabled": false  
}
```

Configure IAM policies for EC2 Serial Console access

By default, your users do not have access to the serial console. Your organization must configure IAM policies to grant your users the required access. For more information, see [Creating IAM policies](#) in the *IAM User Guide*.

For serial console access, create a JSON policy document that includes the `ec2-instance-connect:SendSerialConsoleSSHPublicKey` action. This action grants a user permission to push the public key to the serial console service, which starts a serial console session. We recommend restricting access to specific EC2 instances. Otherwise, all users with this permission can connect to the serial console of all EC2 instances.

Example IAM policies

- [Explicitly allow access to the serial console \(p. 2178\)](#)
- [Explicitly deny access to the serial console \(p. 2179\)](#)
- [Use resource tags to control access to the serial console \(p. 2179\)](#)

Explicitly allow access to the serial console

By default, no one has access to the serial console. To grant access to the serial console, you need to configure a policy to explicitly allow access. We recommend configuring a policy that restricts access to specific instances.

The following policy allows access to the serial console of a specific instance, identified by its instance ID.

Note that the `DescribeInstances`, `DescribeInstanceTypes`, and `GetSerialConsoleAccessStatus` actions do not support resource-level permissions, and therefore all resources, indicated by the * (asterisk), must be specified for these actions.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowDescribeInstances",  
            "Effect": "Allow",  
            "Action": [
```

```
        "ec2:DescribeInstances",
        "ec2:DescribeInstanceTypes",
        "ec2:GetSerialConsoleAccessStatus"
    ],
    "Resource": "*"
},
{
    "Sid": "AllowinstanceBasedSerialConsoleAccess",
    "Effect": "Allow",
    "Action": [
        "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
    ],
    "Resource": "arn:aws:ec2:region:account-id:instance/i-0598c7d356eba48d7"
}
]
```

Explicitly deny access to the serial console

The following IAM policy allows access to the serial console of all instances, denoted by the * (asterisk), and explicitly denies access to the serial console of a specific instance, identified by its ID.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowSerialConsoleAccess",
            "Effect": "Allow",
            "Action": [
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey",
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceTypes",
                "ec2:GetSerialConsoleAccessStatus"
            ],
            "Resource": "*"
        },
        {
            "Sid": "DenySerialConsoleAccess",
            "Effect": "Deny",
            "Action": [
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
            ],
            "Resource": "arn:aws:ec2:region:account-id:instance/i-0598c7d356eba48d7"
        }
    ]
}
```

Use resource tags to control access to the serial console

You can use resource tags to control access to the serial console of an instance.

Attribute-based access control is an authorization strategy that defines permissions based on tags that can be attached to users and AWS resources. For example, the following policy allows a user to initiate a serial console connection for an instance only if that instance's resource tag and the principal's tag have the same `SerialConsole` value for the tag key.

For more information about using tags to control access to your AWS resources, see [Controlling access to AWS resources](#) in the *IAM User Guide*.

Note that the `DescribeInstances`, `DescribeInstanceTypes`, and `GetSerialConsoleAccessStatus` actions do not support resource-level permissions, and therefore all resources, indicated by the * (asterisk), must be specified for these actions.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowDescribeInstances",  
            "Effect": "Allow",  
            "Action": [  
                "ec2:DescribeInstances",  
                "ec2:DescribeInstanceTypes",  
                "ec2:GetSerialConsoleAccessStatus"  
            ],  
            "Resource": "*"  
        },  
        {  
            "Sid": "AllowTagBasedSerialConsoleAccess",  
            "Effect": "Allow",  
            "Action": [  
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey"  
            ],  
            "Resource": "arn:aws:ec2:region:account-id:instance/*",  
            "Condition": {  
                "StringEquals": {  
                    "aws:ResourceTag/SerialConsoleSerialConsole}"  
                }  
            }  
        }  
    ]  
}
```

Connect to the EC2 Serial Console

You can connect to the serial console of your EC2 instance by using the Amazon EC2 console or via SSH. After connecting to the serial console, you can use it for troubleshooting boot, network configuration, and other issues. For more information about troubleshooting, see [Troubleshoot your Windows instance using the EC2 Serial Console \(p. 2184\)](#).

Considerations

- Only 1 active serial console connection is supported per instance.
- The serial console connection typically lasts for 1 hour unless you disconnect from it. However, during system maintenance, Amazon EC2 will disconnect the serial console session.
- It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.
- Supported serial console port for Windows: COM1
- When you connect to the serial console, you might observe a slight drop in your instance's throughput.

Topics

- [Connect using the browser-based client \(p. 2180\)](#)
- [Connect using your own key and SSH client \(p. 2181\)](#)
- [EC2 Serial Console fingerprints \(p. 2182\)](#)

Connect using the browser-based client

You can connect to your EC2 instance's serial console by using the browser-based client. You do this by selecting the instance in the Amazon EC2 console and choosing to connect to the serial console. The browser-based client handles the permissions and provides a successful connection.

EC2 serial console works from most browsers, and supports keyboard and mouse input.

Before connecting, make sure you have completed the [prerequisites \(p. 2172\)](#).

To connect to your instance's serial port using the browser-based client (Amazon EC2 console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Monitor and troubleshoot, EC2 Serial Console, Connect**.

Alternatively, select the instance and choose **Connect, EC2 Serial Console, Connect**.

An in-browser terminal window opens.

4. Press **Enter**. If a login prompt returns, you are connected to the serial console.

If the screen remains black, you can use the following information to help resolve issues with connecting to the serial console:

- **Check that you have configured access to the serial console.** For more information, see [Configure access to the EC2 Serial Console \(p. 2175\)](#).
- **Reboot your instance.** You can reboot your instance by using the EC2 console or the AWS CLI. For more information, see [Reboot your instance \(p. 612\)](#).

Connect using your own key and SSH client

You can use your own SSH key and connect to your instance from the SSH client of your choice while using the serial console API. This enables you to benefit from the serial console capability to push a public key to the instance.

Before connecting, make sure you have completed the [prerequisites \(p. 2172\)](#).

To connect to an instance's serial console using SSH

1. **Push your SSH public key to the instance to start a serial console session**

Use the [send-serial-console-ssh-public-key](#) command to push your SSH public key to the instance. This starts a serial console session.

If a serial console session has already been started for this instance, the command fails because you can only have one session open at a time. It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.

```
C:\> aws ec2-instance-connect send-serial-console-ssh-public-key \
    --instance-id i-001234a4bf70dec41EXAMPLE \
    --serial-port 0 \
    --ssh-public-key file:///my_key.pub \
    --region us-east-1
```

2. **Connect to the serial console using your private key**

Use the **ssh** command to connect to the serial console before the public key is removed from the serial console service. You have 60 seconds before it is removed.

Use the private key that corresponds to the public key.

The user name format is `instance-id.port0`, which comprises the instance ID and port 0. In the following example, the user name is `i-001234a4bf70dec41EXAMPLE.port0`.

For all supported AWS Regions, except AWS GovCloud (US) Regions:

The format of the public DNS name of the serial console service is `serial-console.ec2-instance-connect.region.aws`. In the following example, the serial console service is in the `us-east-1` Region.

```
C:\> ssh -i my_key i-001234a4bf70dec41EXAMPLE.port0@serial-console.ec2-instance-connect.us-east-1.aws
```

For AWS GovCloud (US) Regions only:

The format of the public DNS name of the serial console service in the AWS GovCloud (US) Regions is `serial-console.ec2-instance-connect.GovCloud-region.amazonaws.com`. In the following example, the serial console service is in the `us-gov-east-1` Region.

```
C:\> ssh -i my_key i-001234a4bf70dec41EXAMPLE.port0@serial-console.ec2-instance-connect.us-gov-east-1.amazonaws.com
```

3. (Optional) Verify the fingerprint

When you connect for the first time to the serial console, you are prompted to verify the fingerprint. You can compare the serial console fingerprint with the fingerprint that's displayed for verification. If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, you can confidently connect to the serial console.

The following fingerprint is for the serial console service in the us-east-1 Region. For the fingerprints for each Region, see [EC2 Serial Console fingerprints \(p. 2182\)](#).

```
SHA256:dXwn5ma/xadVMeBZGEru5l2gx+yI5LDiJaLUCz0FMmw
```

Note

The fingerprint only appears the first time you connect to the serial console.

4. Press Enter. If a prompt returns, you are connected to the serial console.

If the screen remains black, you can use the following information to help resolve issues with connecting to the serial console:

- **Check that you have configured access to the serial console.** For more information, see [Configure access to the EC2 Serial Console \(p. 2175\)](#).
- **Reboot your instance.** You can reboot your instance by using the EC2 console or the AWS CLI. For more information, see [Reboot your instance \(p. 612\)](#).

EC2 Serial Console fingerprints

The EC2 Serial Console fingerprint is unique for each AWS Region.

- us-east-1 – US East (N. Virginia)

```
SHA256:dXwn5ma/xadVMeBZGEru5l2gx+yI5LDiJaLUCz0FMmw
```

Disconnect from the EC2 Serial Console

If you no longer need to be connected to your instance's EC2 Serial Console, you can disconnect from it. When you disconnect from the serial console, any shell session running on the instance will continue to run. If you want to end the shell session, you'll need to end it before disconnecting from the serial console.

Considerations

- The serial console connection typically lasts for 1 hour unless you disconnect from it. However, during system maintenance, Amazon EC2 will disconnect the serial console session.
- It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.

The way to disconnect from the serial console depends on the client.

Browser-based client

To disconnect from the serial console, close the serial console in-browser terminal window.

Standard OpenSSH client

To disconnect from the serial console, use the following command to close the SSH connection. This command must be run immediately following a new line.

```
C:\> ~.
```

The command that you use for closing an SSH connection might be different depending on the SSH client that you're using.

Troubleshoot your Windows instance using the EC2 Serial Console

By using EC2 Serial Console, you can troubleshoot boot, network configuration, and other issues by connecting to your instance's serial port.

Topics

- [Use SAC to troubleshoot your Windows instance \(p. 2185\)](#)

For information about troubleshooting your Linux instance, see [Troubleshoot your Linux instance using the EC2 Serial Console](#) in the *Amazon EC2 User Guide for Linux Instances*.

Use SAC to troubleshoot your Windows instance

The Special Admin Console (SAC) capability of Windows provides a way to troubleshoot a Windows instance. By connecting to the instance's serial console and using SAC, you can interrupt the boot process and boot Windows in safe mode.

Before you can use SAC, make sure you have completed the [prerequisites \(p. 2172\)](#), which include granting access to the serial console and enabling SAC and the boot menu.

Note

If you enable SAC on an instance, the EC2 services that rely on password retrieval will not work from the Amazon EC2 console. Windows on Amazon EC2 launch agents (EC2Config, EC2Launch v1, and EC2Launch v2) rely on the serial console to execute various tasks. These tasks do not perform successfully when you enable SAC on an instance. For more information about Windows on Amazon EC2 launch agents, see [Configure your Windows instance](#). If you enable SAC, you can disable it later. For more information, see [Disable SAC and the boot menu \(p. 2188\)](#).

Topics

- [Use SAC \(p. 2185\)](#)
- [Use the boot menu \(p. 2186\)](#)
- [Disable SAC and the boot menu \(p. 2188\)](#)

Use SAC

To use SAC

1. [Connect to the serial console. \(p. 2180\)](#)

If SAC is enabled on the instance, the serial console displays the SAC> prompt.

```
Computer is booting, SAC started and initialized.  
Use the "ch -?" command for information about using channels.  
Use the "?" command for general help.  
  
SAC>?  
EVENT: The CMD command is now available.  
SAC->
```

2. To display the SAC commands, enter ?, and then press **Enter**.

Expected output

```
SAC>?  
ch          Channel management commands. Use ch -? for more help.  
cmd         Create a Command Prompt channel.  
d           Dump the current kernel log.  
f           Toggle detailed or abbreviated tlist info.  
? or help   Display this list.  
i           List all IP network numbers and their IP addresses.  
i <#> <ip> <subnet> <gateway> Set IPv4 addr., subnet and gateway.  
id          Display the computer identification information.  
k <pid>    Kill the given process.  
l <pid>    Lower the priority of a process to the lowest possible.  
lock        Lock access to Command Prompt channels.  
m <pid> <MB-allow> Limit the memory usage of a process to <MB-allow>.  
p           Toggle paging the display.  
r <pid>    Raise the priority of a process by one.  
s           Display the current time and date (24 hour clock used).  
s mm/dd/yyyy hh:mm  Set the current time and date (24 hour clock used).  
t           Tlist.  
restart    Restart the system immediately.  
shutdown   Shutdown the system immediately.  
crashdump Crash the system. You must have crash dump enabled.
```

3. To create a command prompt channel (such as cmd0001 or cmd0002), enter **cmd**, and then press **Enter**.
4. To view the command prompt channel, press **ESC**, and then press **TAB**.

Expected output

```
Name: Cmd0001
Description: Command
Type: VT-UTF8
Channel GUID: ef9f20a0-1287-11eb-82b0-0e4ba51872e5
Application Type GUID: 63d02271-8aa4-11d5-bccf-00b0d014a2d0

Press <esc><tab> for next channel.
Press <esc><tab>0 to return to the SAC channel.
Use any other key to view this channel.
```

5. To switch channels, press **ESC+TAB+channel number** together. For example, to switch to the cmd0002 channel (if it has been created), press **ESC+TAB+2**.
6. Enter the credentials required by the command prompt channel.

```
Please enter login credentials.
Username: Administrator
Domain : .
Password: *****
```

The command prompt is the same full-featured command shell that you get on a desktop, but with the exception that it does not allow the reading of characters that were already output.

```

PS C:\Windows\system32> $computerInfo.Csprocessors[0].Description
Intel64 Family 6 Model 85 Stepping 4
PS C:\Windows\system32> -
```

Use the boot menu

If the instance has the boot menu enabled and is restarted after connecting via SSH, you should see the boot menu, as follows.

Boot menu commands

ENTER

Starts the selected entry of the operating system.

TAB

Switches to the Tools menu.

ESC

Cancels and restarts the instance.

ESC followed by 8

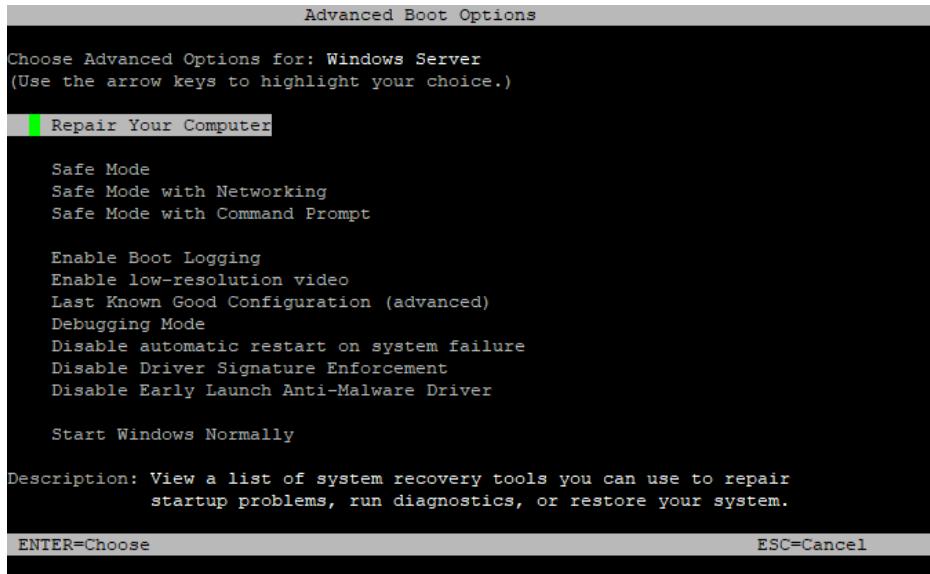

Equivalent to pressing **F8**. Shows advanced options for the selected item.

ESC key + left arrow

Goes back to the initial boot menu.

Note

The ESC key alone does not take you back to the main menu because Windows is waiting to see if an escape sequence is in progress.

Disable SAC and the boot menu

If you enable SAC and the boot menu, you can disable these features later.

Use one of the following methods to disable SAC and the boot menu on an instance.

PowerShell

To disable SAC and the boot menu on a Windows instance

1. [Connect \(p. 626\)](#) to your instance and perform the following steps from an elevated PowerShell command line.
2. First disable the boot menu by changing the value to no.

```
bcdedit /set '{bootmgr}' displaybootmenu no
```

3. Then disable SAC by changing the value to off.

```
bcdedit /ems '{current}' off
```

4. Apply the updated configuration by rebooting the instance.

```
shutdown -r -t 0
```

Command prompt

To disable SAC and the boot menu on a Windows instance

1. [Connect \(p. 626\)](#) to your instance and perform the following steps from the command prompt.
2. First disable the boot menu by changing the value to no.

```
bcdedit /set {bootmgr} displaybootmenu no
```

3. Then disable SAC by changing the value to off.

```
bcdedit /ems {current} off
```

4. Apply the updated configuration by rebooting the instance.

```
shutdown -r -t 0
```

Send a diagnostic interrupt (for advanced users)

Warning

Diagnostic interrupts are intended for use by advanced users. Incorrect usage could negatively impact your instance. Sending a diagnostic interrupt to an instance could trigger an instance to crash and reboot, which could lead to the loss of data.

You can send a diagnostic interrupt to an unreachable or unresponsive Windows instance to manually trigger a *stop error*. Stop errors are commonly referred to as *blue screen errors*.

In general, Windows operating systems crash and reboot when a stop error occurs, but the specific behavior depends on its configuration. A stop error can also cause the operating system to write debugging information, such as a kernel memory dump, to a file. You can then use this information to conduct root cause analysis to debug the instance.

The memory dump data is generated locally by the operating system on the instance itself.

Before sending a diagnostic interrupt to your instance, we recommend that you consult the documentation for your operating system and then make the necessary configuration changes.

Contents

- [Supported instance types \(p. 2189\)](#)
- [Prerequisites \(p. 2189\)](#)
- [Send a diagnostic interrupt \(p. 2190\)](#)

Supported instance types

Diagnostic interrupt is supported on all Nitro-based instance types, except those powered by AWS Graviton processors. For more information, see [Instances built on the Nitro System \(p. 218\)](#) and [AWS Graviton](#).

Prerequisites

Before using a diagnostic interrupt, you should configure your instance's operating system to perform the actions you need when a stop error occurs.

To configure Windows to generate a memory dump when a stop error occurs

1. Connect to your instance.
2. Open the **Control Panel** and choose **System, Advanced system settings**.
3. In the **System Properties** dialog box, choose the **Advanced** tab.
4. In the **Startup and Recovery** section, choose **Settings....**
5. In the **System failure** section, configure the settings as needed, and then choose **OK**.

For more information about configuring Windows stop errors, see [Overview of memory dump file options for Windows](#).

Send a diagnostic interrupt

After you have completed the necessary configuration changes, you can send a diagnostic interrupt to your instance using the AWS CLI or Amazon EC2 API.

To send a diagnostic interrupt to your instance (AWS CLI)

Use the [send-diagnostic-interrupt](#) command and specify the instance ID.

```
aws ec2 send-diagnostic-interrupt --instance-id i-1234567890abcdef0
```

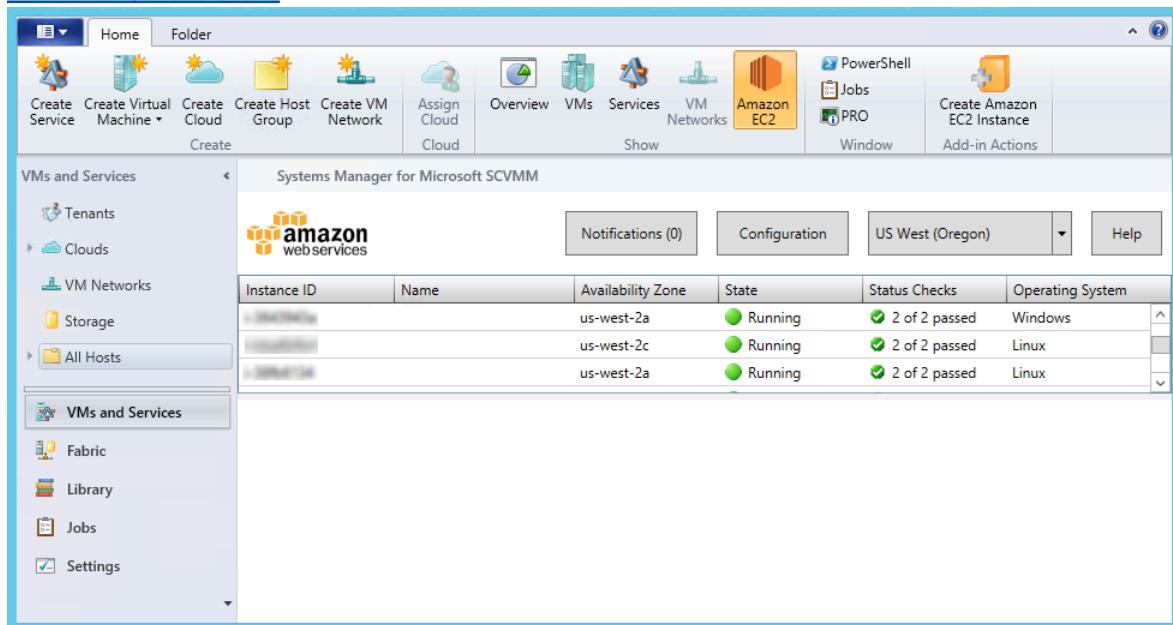

To send a diagnostic interrupt to your instance (AWS Tools for Windows PowerShell)

Use the [Send-EC2DiagnosticInterrupt](#) cmdlet and specify the instance ID.

```
PS C:\> Send-EC2DiagnosticInterrupt -InstanceId i-1234567890abcdef0
```

AWS Systems Manager for Microsoft System Center VMM

AWS Systems Manager for Microsoft System Center Virtual Machine Manager (SCVMM) provides a simple, easy-to-use interface for managing AWS resources, such as EC2 instances, from Microsoft SCVMM. It is implemented as an add-in for the VMM console. For more information, see [AWS Add-ins for Microsoft System Center](#).

Features

- Administrators can grant permissions to users so that they can manage EC2 instances from SCVMM.
- Users can launch, view, reboot, stop, start, and terminate instances, if they have the required permissions.
- Users can get the passwords for their Windows instances and connect to them using RDP.
- Users can get the public DNS names for their Linux instances and connect to them using SSH.
- Users can import their Hyper-V Windows virtual machines from SCVMM to Amazon EC2.

Limitations

- Users must have an account that they can use to log in to SCVMM.
- You can't import Linux virtual machines from SCVMM to Amazon EC2.

- This is not a comprehensive tool for creating and managing AWS resources. The add-in enables SCVMM users to get started quickly with the basic tasks for managing their EC2 instances. Future releases might support managing additional AWS resources.

Requirements

- An AWS account
- Microsoft System Center VMM 2012 R2 or System Center VMM 2012 SP1 with the latest update roll-up

Get started

To get started, see the following documentation:

- [Setting Up \(p. 2192\)](#)
- [Managing EC2 Instances \(p. 2196\)](#)
- [Troubleshooting \(p. 2203\)](#)

Set up AWS Systems Manager for Microsoft SCVMM

When you set up AWS Systems Manager, users in your organization can access your AWS resources. The process involves creating accounts, deploying the add-in, and providing your credentials.

Tasks

- [Sign up for AWS \(p. 2192\)](#)
- [Set up access for users \(p. 2192\)](#)
- [Deploy the add-in \(p. 2195\)](#)
- [Provide your AWS credentials \(p. 2195\)](#)

Sign up for AWS

When you sign up for Amazon Web Services, your AWS account is automatically signed up for all services in AWS. You are charged only for the services that you use.

If you have an AWS account already, skip to the next task. If you don't have an AWS account, see [Sign up for an AWS account \(p. 7\)](#) for instructions on how to create one.

Set up access for users

The first time that you use Systems Manager, you must provide AWS credentials. To enable multiple users to access the same AWS account using unique credentials and permissions, create a user for each user. You can create one or more groups with policies that grant permissions to perform limited tasks. Then you can create one or more users, and add each user to the appropriate group.

To create an Administrators group

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.

2. In the navigation pane, choose **Groups** and then choose **Create New Group**.
3. In the **Group Name** box, specify **Administrators** and then choose **Next Step**.
4. On the **Attach Policy** page, select the **AdministratorAccess** AWS managed policy.
5. Choose **Next Step** and then choose **Create Group**.

To create a group with limited access to Amazon EC2

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Groups** and then choose **Create New Group**.
3. In the **Group Name** box, specify a meaningful name for the group and then choose **Next Step**.
4. On the **Attach Policy** page, do not select an AWS managed policy — choose **Next Step**, and then choose **Create Group**.
5. Choose the name of the group you've just created. On the **Permissions** tab, choose **Inline Policies**, and then click **here**.
6. Select the **Custom Policy** radio button and then choose **Select**.
7. Enter a name for the policy and a policy document that grants limited access to Amazon EC2, and then choose **Apply Policy**. For example, you can specify one of the following custom policies.

Grant users in this group permission to view information about EC2 instances only

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ec2:Describe*",  
                "iam>ListInstanceProfiles"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

Grant users in this group permission to perform all operations on EC2 instances that are supported by the add-in

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "iam>ListInstanceProfiles",  
                "ec2:Describe*", "ec2>CreateKeyPair",  
                "ec2>CreateTags", "ec2>DeleteTags",  
                "ec2:RunInstances", "ec2:GetPasswordData",  
                "ec2:RebootInstances", "ec2:StartInstances",  
                "ec2:StopInstances", "ec2:TerminateInstances"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

Grant users in this group permission to import a VM to Amazon EC2

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3>ListAllMyBuckets", "s3>CreateBucket",  
                "s3>DeleteBucket", "s3>DeleteObject",  
                "s3>GetBucketLocation", "s3>GetObject",  
                "s3>ListBucket", "s3>PutObject",  
                "ec2>DescribeTags", "ec2>CancelConversionTask",  
                "ec2>DescribeConversionTasks", "ec2>DescribeInstanceAttribute",  
                "ec2>CreateImage", "ec2>AttachVolume",  
                "ec2>ImportInstance", "ec2>ImportVolume",  
                "dynamodb>DescribeTable", "dynamodb>CreateTable",  
                "dynamodb>Scan", "dynamodb>PutItem", "dynamodb>UpdateItem"  
            ],  
            "Resource": "*"  
        }  
    ]  
}
```

To create a user, get the user's AWS credentials, and grant the user permissions

Users need programmatic access if they want to interact with AWS outside of the AWS Management Console. The way to grant programmatic access depends on the type of user that's accessing AWS.

To grant users programmatic access, choose one of the following options.

Which user needs programmatic access?	To	By
Workforce identity (Users managed in IAM Identity Center)	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	<p>Following the instructions for the interface that you want to use.</p> <ul style="list-style-type: none">For the AWS CLI, see Configuring the AWS CLI to use AWS IAM Identity Center (successor to AWS Single Sign-On) in the <i>AWS Command Line Interface User Guide</i>.For AWS SDKs, tools, and AWS APIs, see IAM Identity Center authentication in the <i>AWS SDKs and Tools Reference Guide</i>.
IAM	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	<p>Following the instructions in Using temporary credentials with AWS resources in the <i>IAM User Guide</i>.</p>
IAM	(Not recommended) Use long-term credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	Following the instructions for the interface that you want to use.

Which user needs programmatic access?	To	By
		<ul style="list-style-type: none">For the AWS CLI, see Authenticating using IAM user credentials in the <i>AWS Command Line Interface User Guide</i>.For AWS SDKs and tools, see Authenticate using long-term credentials in the <i>AWS SDKs and Tools Reference Guide</i>.For AWS APIs, see Managing access keys for IAM users in the <i>IAM User Guide</i>.

Deploy the add-in

Add-ins for System Center VMM are distributed as .zip files. To deploy the add-in, use the following procedure.

To deploy the add-in

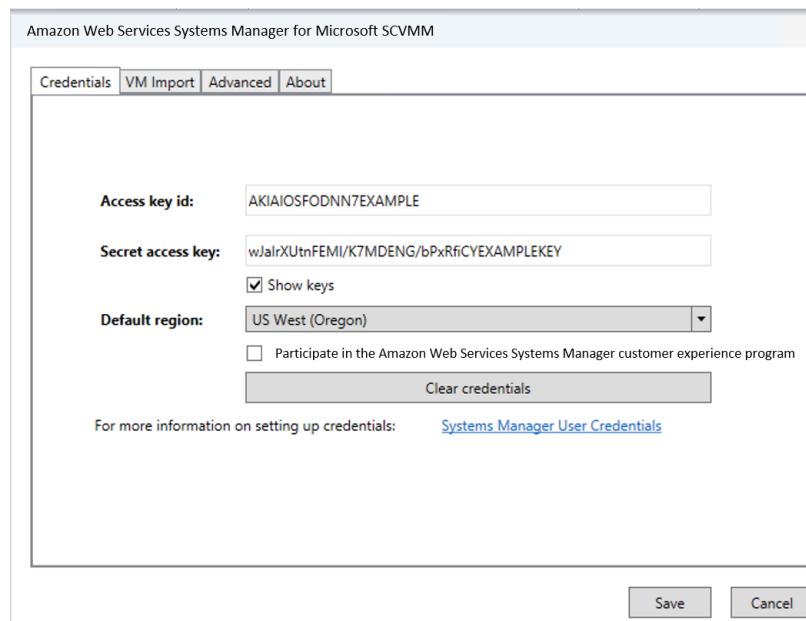

- From your instance, go to [AWS Systems Manager for Microsoft System Center Virtual Machine Manager](#) and click **SCVMM**. Save the aws-systems-manager-1.5.zip file to your instance.
- Open the VMM console.
- In the navigation pane, click **Settings** and then click **Console Add-Ins**.
- On the ribbon, click **Import Console Add-in**.
- On the **Select an Add-in** page, click **Browse** and select the aws-systems-manager-1.5.zip file for the add-in that you downloaded.
- Ignore any warnings that there are assemblies in the add-in that are not signed by a trusted authority. Select **Continue installing this add-in anyway** and then click **Next**.
- On the **Summary** page, click **Finish**.
- When the add-in is imported, the status of the job is **Completed**. You can close the **Jobs** window.

Provide your AWS credentials

When you use the Systems Manager for the first time, you must provide your AWS credentials. Your access keys identify you to AWS. There are two types of access keys: access key IDs (for example, AKIAIOSFODNN7EXAMPLE) and secret access keys (for example, wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY). You should have stored your access keys in a safe place when you received them.

To provide your AWS credentials

- Open the VMM console.
- In the navigation pane, click **VMs and Services**.
- On the ribbon, click **Amazon EC2**.
- On the **Credentials** tab, specify your AWS credentials, select a default region, and then click **Save**.

To change these credentials at any time, click **Configuration**.

Manage EC2 instances using AWS Systems Manager for Microsoft SCVMM

After you log in to the Systems Manager console using your AWS credentials, you can manage your EC2 instances.

Tasks

- [Create an EC2 Instance \(p. 2196\)](#)
- [View your instances \(p. 2199\)](#)
- [Connect to your instance \(p. 2199\)](#)
- [Reboot your instance \(p. 2200\)](#)
- [Stop your instance \(p. 2200\)](#)
- [Start your instance \(p. 2200\)](#)
- [Terminate your instance \(p. 2200\)](#)

Create an EC2 Instance

The permissions that you've been granted by your administrator determine whether you can create instances.

Prerequisites

- A virtual private cloud (VPC) with a subnet in the Availability Zone where you'll launch the instance. For more information about creating a VPC, see the [Amazon VPC Getting Started Guide](#).

To create an EC2 instance

1. Open SCVMM.
2. On the ribbon, click **Create Amazon EC2 Instance**.
3. Complete the **Create Amazon EC2 Instance** dialog box as follows:
 - a. Select a Region for your instance. By default, we select the Region that you configured as your default Region.
 - b. Select a template (known as an AMI) for your instance. To use an AMI provided by Amazon, select **Windows** or **Linux** and then select an AMI from **Image**. To use an AMI that you created, select **My images** and then select the AMI from **Image**.
 - c. Select an instance type for the instance. First, select one of the latest instance families from **Family**, and then select an instance type from **Instance type**. To include previous generation instance families in the list, select **Show previous generations**. For more information, see [Amazon EC2 Instances](#) and [Previous Generation Instances](#).
 - d. Create or select a key pair. To create a key pair, select **Create a new key pair** from **Key pair name** and enter a name for the key pair in the highlighted field (for example, `my-key-pair`).
 - e. (Optional) Under **Advanced settings**, specify a display name for the instance.
 - f. (Optional) Under **Advanced settings**, select a VPC from **Network (VPC)**. Note that this list includes all VPCs for the region, including VPCs created using the Amazon VPC console and the default VPC (if it exists). If you have a default VPC in this region, we select it by default. If the text is "There is no VPC available for launch or import operations in this region", then you must create a VPC in this Region using the Amazon VPC console.
 - g. (Optional) Under **Advanced settings**, select a subnet from **Subnet**. Note that this list includes all subnets for the selected VPC, including any default subnets. If this list is empty, you must add a subnet to the VPC using the Amazon VPC console, or select a different VPC. Otherwise, we select a subnet for you.
 - h. (Optional) Under **Advanced settings**, create a security group or select one or more security groups. If you select **Create default security group**, we create a security group that grants RDP and SSH access to everyone, which you can modify using the Amazon EC2 or Amazon VPC console. You can enter a name for this security group in the **Group name** box.
 - i. (Optional) Under **Advanced settings**, select an IAM role. If this list is empty, you can create a role using the IAM console.

Create Amazon EC2 Instance

To launch one new instance, complete the fields, and then click Create.

Region: US West (Oregon)

Operating system: Windows Linux My images

Image: Microsoft Windows Server 2012 R2 Base (ami-29d18719)

Family: General purpose Show previous generations

Instance type: m3.medium vCPUs: 1 Memory: 3.75 GB

Key pair name: Create a new key pair my-key-pair

Advanced settings

Name: my-instance

Root volume: General Purpose (SSD) Size (GiB): 30

Network (VPC): vpc-98eb5ef5 (10.0.0.0/16)

Subnet: subnet-6bea5f06 (10.0.0.0/24) (us-west-2c)

Security groups: Create default security group
sg-8422d1eb (default)
sg-7b845f14 (my-security-group)

Group name:

IAM role: my-iam-role

Create **Cancel**

- Click **Create**. If you are creating a key pair, you are prompted to save the .pem file. Save this file in a secure place; you'll need it to log in to your instance. You'll receive confirmation that the instance has launched. Click **Close**.

After you've created your instance, it appears in the list of instances for the Region in which you launched it. Initially, the status of the instance is pending. After the status changes to running, your instance is ready for use.

You can manage the lifecycle of your instance using Systems Manager, as described on this page. To perform other tasks, such as the following, you must use the AWS Management Console:

- [Attach an Amazon EBS volume to your instance \(p. 1729\)](#)
- [Associate an Elastic IP address with your instance \(p. 1272\)](#)
- [Enable termination protection \(p. 618\)](#)

View your instances

The permissions that your administrator grants you determine whether you can view instances and get detailed information about them.

To view your instances and get detailed information

1. Open the [AWS Systems Manager console](#).
2. From the list of Regions, select a Region.
3. From the list of instances, select one or more instances.
4. In the lower pane, click the down arrow next to each instance to view detailed information about the instance.

Instance type:	m3.medium	Vpc ID:	vpc-f1663d98
Tenancy:	default	Subnet ID:	subnet-c9663da0
Image ID:	ami-29d18719	Network interfaces:	eni-89b0bed0
Operating system:	Windows		

Connect to your instance

You can log in to an EC2 instance if you have the private key (.pem file) for the key pair that was specified when launching the instance. The tool that you'll use to connect to your instance depends on whether the instance is a Windows instance or a Linux instance.

To connect to a Windows EC2 instance

1. Open AWS Systems Manager.
2. From the list of instances, select the instance, right-click, and then click **Retrieve Windows Password**.
3. In the **Retrieve Default Windows Administrator Password** dialog box, click **Browse**. Select the private key file for the key pair and then click **Open**.
4. Click **Decrypt Password**. Save the password or copy it to the clipboard.
5. Select the instance, right-click, and then click **Connect via RDP**. When prompted for credentials, use the name of the administrator account and the password that you saved in the previous step.
6. Because the certificate is self-signed, you might get a warning that the security certificate is not from a trusted certifying authority. Click **Yes** to continue.

If the connection fails, see [Troubleshoot Windows instances](#) in the *Amazon EC2 User Guide for Windows Instances*.

To connect to a Linux EC2 instance

1. Open AWS Systems Manager.
2. From the list of instances, select the instance.

3. In the lower pane, click the down arrow next to the instance ID to view detailed information about the instance.
4. Locate the public DNS name. You'll need this information to connect to your instance.
5. Connect to the instance using PuTTY. For step-by-step instructions, see [Connect to your Linux instance from Windows using PuTTY](#) in the *Amazon EC2 User Guide for Linux Instances*.

Reboot your instance

The permissions that you've been granted by your administrator determine whether you can reboot instances.

To reboot your instance

1. Open AWS Systems Manager.
2. From the list of instances, select the instance.
3. Right-click the instance, and then click **Reset (Reboot)**.
4. When prompted for confirmation, click **Yes**.

Stop your instance

The permissions that you've been granted by your administrator determine whether you can stop instances.

To stop your instance

1. Open AWS Systems Manager.
2. From the list of instances, select the instance.
3. Right-click the instance, and then click **Shut Down (Stop)**.
4. When prompted for confirmation, click **Yes**.

Start your instance

The permissions that you've been granted by your administrator determine whether you can start instances.

To start your instance

1. Open AWS Systems Manager.
2. From the list of instances, select the instance.
3. Right-click the instance, and then click **Power On (Start)**.
4. When prompted for confirmation, click **Yes**.

If you get a quota error when you try to start an instance, you have reached your concurrent running instance limit. The default limit for your AWS account is 20. If you need additional running instances, complete the form at [Request to Increase Amazon EC2 Instance Limit](#).

Terminate your instance

The permissions that you've been granted by your administrator determine whether you can terminate instances.

To terminate your instance

1. Open AWS Systems Manager.
2. From the list of instances, select the instance.
3. Right-click the instance, and then click **Delete (Terminate)**.
4. When prompted for confirmation, click **Yes**.

Import your virtual machine using AWS Systems Manager for Microsoft SCVMM

You can launch an EC2 instance from a virtual machine that you import from SCVMM to Amazon EC2.

Important

You can't import Linux virtual machines from SCVMM to Amazon EC2.

Contents

- [Prerequisites \(p. 2201\)](#)
- [Import your virtual machine \(p. 2201\)](#)
- [Check the import task status \(p. 2202\)](#)
- [Back up your imported instance \(p. 2203\)](#)

Prerequisites

- Ensure that your VM is ready. For more information, see [Prepare Your VM](#) in the *VM Import/Export User Guide*.
- In AWS Systems Manager, click **Configuration**, select the **VM Import** tab, and review the following settings:
 - **S3 bucket prefix:** We create a bucket for disk images to be uploaded before they are imported. The name of the bucket starts with the prefix listed here and includes the Region (for example, us-east-2). To delete the disk images after they are imported, select **Clean up S3 bucket after import**.
 - **VM image export path:** A location for the disk images exported from the VM. To delete the disk images after they are imported, select **Clean up export path after import**.
 - **Alternate Hyper-V PowerShell module path:** The location of the Hyper-V PowerShell module, if it's not installed in the standard location. For more information, see [Installing the Hyper-V Management Tools](#).

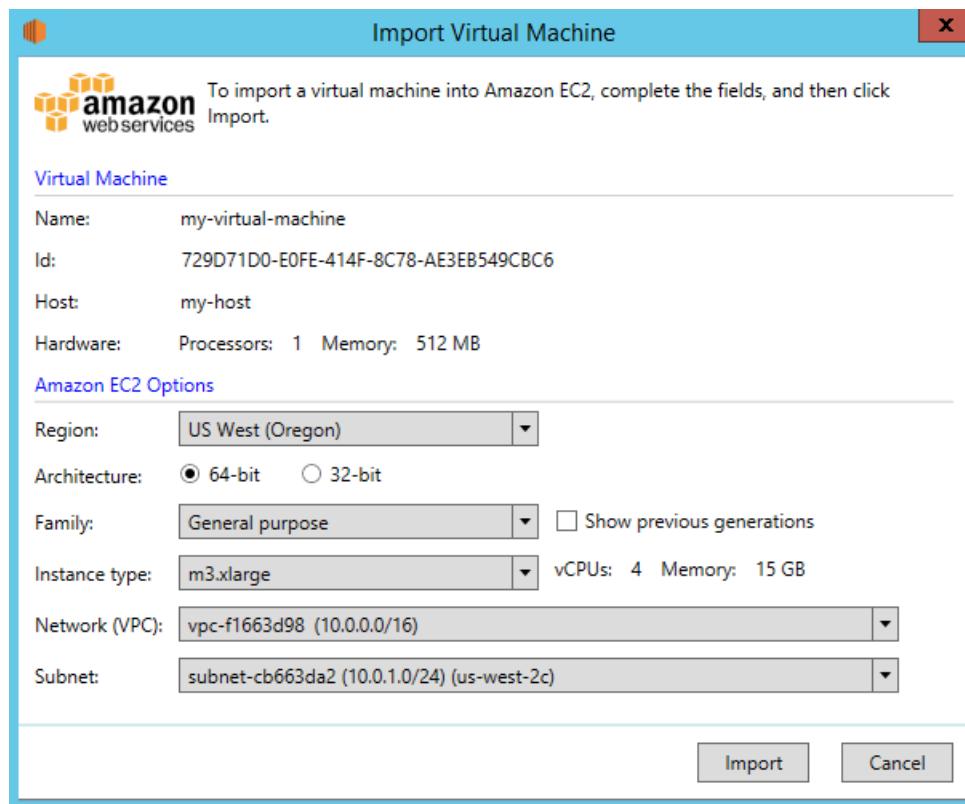

Import your virtual machine

The permissions that you've been granted by your administrator determine whether you can import HyperV Windows virtual machines from SCVMM to AWS.

To import your virtual machine

1. Open SCVMM.
2. On the ribbon, click **VMs**. Select your virtual machine from the list.
3. On the ribbon, click **Import VM to Amazon EC2**.
4. Complete the **Import Virtual Machine** dialog box as follows:

- a. Select a Region for the instance. By default, we select the Region that you configured as your default Region.
- b. Select an instance type for the instance. First, select one of the latest instance families from **Family**, and then select an instance type from **Instance type**. To include previous generation instance families in the list, select **Show previous generations**. For more information, see [Amazon EC2 Instances](#) and [Previous Generation Instances](#).
- c. Select a VPC from **Network (VPC)**. Note that this list includes all VPCs for the region, including VPCs created using the Amazon VPC console and the default VPC (if it exists). If you have a default VPC in this region, we select it by default. If the text is "There is no VPC available for launch or import operations in this region", then you must create a VPC in this region using the Amazon VPC console.
- d. Select a subnet from **Subnet**. Note that this list includes all subnets for the selected VPC, including any default subnets. If this list is empty, you must add a subnet to the VPC using the Amazon VPC console, or select a different VPC. Otherwise, we select a subnet for you.

5. Click **Import**. If you haven't specified the required information in the **VM Import** tab, you'll receive an error asking you to provide the required information. Otherwise, you'll receive confirmation that the import task has started. Click **Close**.

Check the import task status

The import task can take several hours to complete. To view the current status, open AWS Systems Manager and click **Notifications**.

You'll receive the following notifications as the import task progresses:

- Import VM: Created Import VM Task
- Import VM: Export VM Disk Image Done
- Import VM: Upload to S3
- Import VM: Image Conversion Starting
- Import VM: Image Conversion Done
- Import VM: Import Complete

Note that you'll receive the Import VM: Upload to S3, Import VM: Image Conversion Starting, and Import VM: Image Conversion Done notifications for each disk image converted.

If the import task fails, you'll receive the notification Import VM: Import Failed. For more information about troubleshooting issues with import tasks, see [Errors importing a virtual machine \(p. 2204\)](#).

Back up your imported instance

After the import operation completes, the instance runs until it is terminated. If your instance is terminated, you can't connect to or recover the instance. To ensure that you can start a new instance with the same software as an imported instance if needed, create an Amazon Machine Image (AMI) from the imported instance. For more information, see [Create a custom Windows AMI \(p. 151\)](#).

Troubleshoot AWS Systems Manager for Microsoft SCVMM

The following are common errors and troubleshooting steps.

Contents

- [Error: Add-in cannot be installed \(p. 2203\)](#)
- [Installation errors \(p. 2204\)](#)
- [Check the log file \(p. 2204\)](#)
- [Errors importing a virtual machine \(p. 2204\)](#)
- [Uninstall the add-in \(p. 2205\)](#)

Error: Add-in cannot be installed

If you receive the following error, try installing [KB2918659](#) on the computer running the VMM console. For more information, see [Description of System Center 2012 SP1 Update Rollup 5](#). Note that you don't need to install all the updates listed in this article to address this issue, just KB2918659.

```
Add-in cannot be installed
The assembly "Amazon.Scvmm.Addin" referenced to by add-in component "AWS Systems Manager
for
Microsoft SCVMM" could not be found in the add-in package. This could be due to the
following
reasons:
1. The assembly was not included with the add-in package.
2. The AssemblyName attribute for the add-in does not match the name of the add-in
assembly.
3. The assembly file is corrupt and cannot be loaded.
```

Installation errors

If you receive one of the following errors during installation, it is likely due to an issue with SCVMM:

Could not update managed code add-in pipeline due to the following error:
Access to the path 'C:\Program Files\Microsoft System Center 2012\Virtual Machine Manager\Bin\AddInPipeline\PipelineSegments.store' is denied.

Could not update managed code add-in pipeline due to the following error:
The required folder 'C:\Program Files\Microsoft System Center 2012\Virtual Machine Manager\Bin\AddInPipeline\HostSideAdapters' does not exist.

Add-in cannot be installed
The assembly "Microsoft.SystemCenter.VirtualMachineManager.UIAddIns.dll" referenced by the add-in assembly "Amazon.Scvmm.AddIn" could not be found in the add-in package. Make sure that this assembly was included with the add-in package.

Try one of the following steps to work around this issue:

- Grant authenticated users permission to read and run the C:\Program Files\Microsoft System Center 2012\Virtual Machine Manager\Bin\AddInPipeline folder. In Windows Explorer, right-click the folder, select **Properties**, and then select the **Security** tab.
- Close the SCVMM console and start it one time as an administrator. From the **Start** menu, locate SCVMM, right-click, and then select **Run as administrator**.

Check the log file

If you have a problem using the add-in, check the generated log file, %APPDATA%\Amazon\SCVMM\ec2addin.log, for useful information.

Errors importing a virtual machine

The log file, %APPDATA%\Amazon\SCVMM\ec2addin.log, contains detailed information about the status of an import task. The following are common errors that you might see in the log file when you import your VM from SCVMM to Amazon EC2.

Error: Unable to extract Hyper-V VirtualMachine object

Solution: Configure the path to the Hyper-V PowerShell module.

Error: You do not have permission to perform the operation

This error usually occurs when Hyper-V can't save the VM image into the configured path. To resolve this issue, do the following.

- Create a directory on the Hyper-V server. For example: C:\vmimages.
- Share the directory you just created in Hyper-V. Any user running SCVMM should be given access to the directory.
- In the plugin, set the export path to \\hyperv\vmimages.
- Perform the export.

The image will be exported to a local directory on the Hyper-V server. The SCVMM plugin will pull it from Hyper-V, and upload into Amazon S3.

Uninstall the add-in

If you need to uninstall the add-in, use the following procedure.

To uninstall the add-in

1. Open the VMM console.
2. Select the **Settings** workspace, and then click **Console Add-Ins**.
3. Select **AWS Systems Manager for Microsoft SCVMM**.
4. On the ribbon, click **Remove**.
5. When prompted for confirmation, click **Yes**.

If you reinstall the add-in after uninstalling it and receive the following error, delete the path as suggested by the error message.

```
Error (27301)
There was an error while installing the add-in. Please ensure that the following path does
not
exist and then try the installation again.

C:\Program Files\Microsoft System Center 2012\Virtual Machine Manager\Bin\AddInPipeline\
AddIns\EC2WINDOWS...
```

AWS Management Pack for Microsoft System Center

AWS offers a complete set of infrastructure and application services for running almost anything in the cloud—from enterprise applications and big data projects to social games and mobile apps. The AWS Management Pack for Microsoft System Center provides availability and performance monitoring capabilities for your applications running in AWS.

The AWS Management Pack allows Microsoft System Center Operations Manager to access your AWS resources (such as instances and volumes), so that it can collect performance data and monitor your AWS resources. The AWS Management Pack is an extension to System Center Operations Manager. There are two versions of the AWS Management Pack: one for System Center 2012 — Operations Manager and another for System Center Operations Manager 2007 R2.

The AWS Management Pack uses Amazon CloudWatch metrics and alarms to monitor your AWS resources. Amazon CloudWatch metrics appear in Microsoft System Center as performance counters and Amazon CloudWatch alarms appear as alerts.

You can monitor the following resources:

- EC2 instances
- EBS volumes
- Classic Load Balancers
- Amazon EC2 Auto Scaling groups and Availability Zones
- Elastic Beanstalk applications
- CloudFormation stacks
- CloudWatch Alarms
- CloudWatch Custom Metrics

- [Uninstall the AWS Management Pack \(p. 2236\)](#)
- [Troubleshoot the AWS Management Pack \(p. 2236\)](#)

Overview of AWS Management Pack for System Center 2012

The AWS Management Pack for System Center 2012 — Operations Manager uses a resource pool that contains one or more management servers to discover and monitor your AWS resources. You can add management servers to the pool as you increase the number of AWS resources that you use.

The following diagram shows the main components of AWS Management Pack.

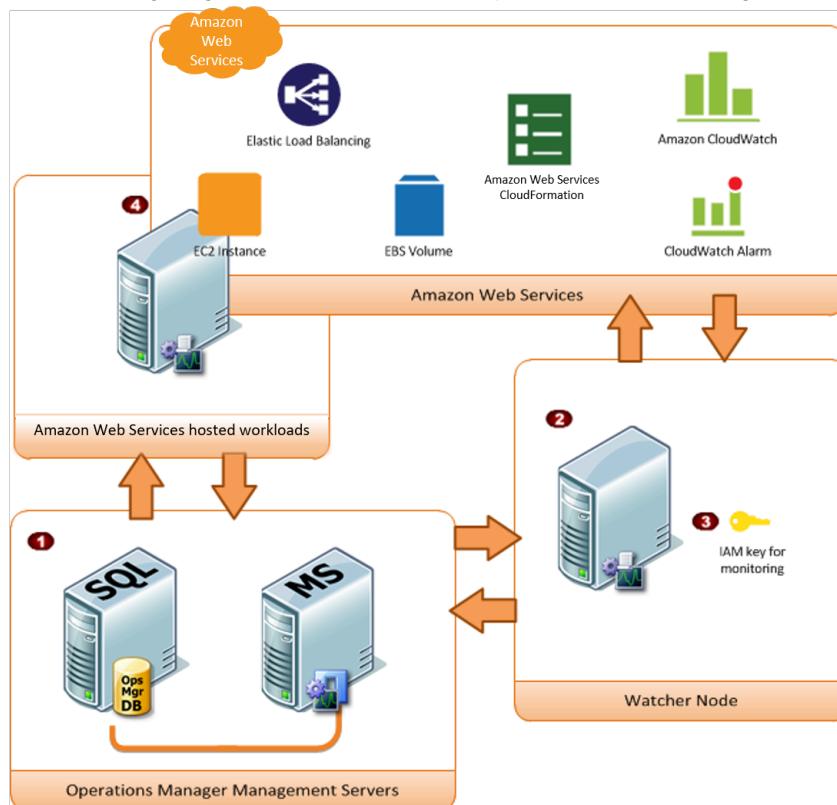

Item	Component	Description
①	Operations Manager infrastructure	One or more management servers and their dependencies, such as Microsoft SQL Server and a Microsoft Active Directory domain. These servers can either be deployed on-premises or in the AWS cloud; both scenarios are supported.
②	Resource pool	One or more management servers used for communicating with AWS using the AWS SDK for .NET. These servers must have Internet connectivity.
③	AWS credentials.	An access key ID and a secret access key used by the management servers to make AWS API calls. You must specify these credentials while you configure the AWS Management Pack. You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the <i>IAM User Guide</i> .

Item	Component	Description
④	EC2 instances	Virtual computers running in the AWS Cloud. Some instances might have the Operations Manager Agent installed, others might not. When you install Operations Manager Agent you can see the operating system and application health apart from the instance health.

Overview of AWS Management Pack for System Center 2007 R2

The AWS Management Pack for System Center Operations Manager 2007 R2 uses a designated computer that connects to your System Center environment and has Internet access, called a *watcher node*, to call AWS APIs to remotely discover and collect information about your AWS resources.

The following diagram shows the main components of AWS Management Pack.

Item	Component	Description
①	Operations Manager infrastructure	One or more management servers and their dependencies, such as Microsoft SQL Server and a Microsoft Active Directory domain. These servers can either be deployed on-premises or in the AWS Cloud; both scenarios are supported.
②	Watcher node	A designated agent-managed computer used for communicating with AWS using the AWS SDK for .NET. It can

Item	Component	Description
		either be deployed on-premises or in the AWS Cloud, but it must be an agent-managed computer, and it must have Internet connectivity. You can use exactly one watcher node to monitor an AWS account. However, one watcher node can monitor multiple AWS accounts. For more information about setting up a watcher node, see Deploying Windows Agents in the Microsoft System Center documentation.
3	AWS credentials	An access key ID and a secret access key used by the watcher node to make AWS API calls. You must specify these credentials while you configure the AWS Management Pack. You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the <i>IAM User Guide</i> .
4	EC2 instances	Virtual computers running in the AWS Cloud. Some instances might have the Operations Manager Agent installed, others might not. When you install the Operations Manager Agent you can see the operating system and application health apart from the instance health.

Download the AWS Management Pack

To get started, download the AWS Management Pack. The AWS Management Pack is free. You might incur charges for Amazon CloudWatch, depending on how you configure monitoring or how many AWS resources you monitor.

System Center 2012

Before you download the AWS Management Pack, ensure that your systems meet the following system requirements and prerequisites.

System Requirements

- System Center Operations Manager 2012 R2 or System Center Operations Manager 2012 SP1
- Cumulative Update 1 or later. You must deploy the update to the management servers monitoring AWS resources, as well as agents running the watcher nodes and agents to be monitored by the AWS Management Pack. We recommend that you deploy the latest available Operations Manager updates on all computers monitoring AWS resources.
- Microsoft.Unix.Library MP version 7.3.2026.0 or later

Prerequisites

- Your data center must have at least one management server configured with Internet connectivity. The management servers must have the Microsoft .NET Framework version 4.5 or later and PowerShell 2.0 or later installed.
- The action account for the management server must have local administrator privileges on the management server.

To download the AWS Management Pack

1. On the [AWS Add-Ins for Microsoft System Center](#) website, click **SCOM 2012**.
2. Save AWS-SCOM-MP-2.5.zip to your computer and unzip it.

Continue with [Deploy the AWS Management Pack \(p. 2210\)](#).

System Center 2007 R2

Before you download the AWS Management Pack, ensure that your systems meet the following system requirements and prerequisites.

System Requirements

- System Center Operations Manager 2007 R2
- Microsoft.Unix.Library MP version 6.1.7000.256 or later

Prerequisites

- Your data center must have an agent-managed computer with Internet connectivity that you designate as the watcher node. The watcher node must have the following Agent Proxy option enabled: **Allow this agent to act as a proxy and discover managed objects on other computers**. The watcher node must have the Microsoft .NET Framework version 3.5.1 or later and PowerShell 2.0 or later installed.
- The action account for the watcher node must have local administrator privileges on the watcher node.
- You must ensure that your watcher node has the agent installed, has Internet access, and can communicate with the management servers in your data center. For more information, see [Deploying Windows Agents](#) in the Microsoft System Center documentation.

To download the AWS Management Pack

1. On the [AWS Add-Ins for Microsoft System Center](#) website, click **SCOM 2007**.
2. Save AWS-MP-Setup-2.5.msi to your computer.

Continue with [Deploy the AWS Management Pack \(p. 2210\)](#).

Deploy the AWS Management Pack

Before you can deploy the AWS Management Pack, you must download it. For more information, see [Download the AWS Management Pack \(p. 2209\)](#).

Tasks

- [Step 1: Install the AWS Management Pack \(p. 2211\)](#)

- [Step 2: Configure the watcher node \(p. 2212\)](#)
- [Step 3: Create an AWS Run As account \(p. 2213\)](#)
- [Step 4: Run the Add Monitoring wizard \(p. 2216\)](#)
- [Step 5: Configure ports and endpoints \(p. 2220\)](#)

Step 1: Install the AWS Management Pack

After you download the AWS Management Pack, you must configure it to monitor one or more AWS accounts.

System Center 2012

To install the AWS Management Pack

1. In the Operations console, on the **Go** menu, click **Administration**, and then click **Management Packs**.
2. In the **Actions** pane, click **Import Management Packs**.
3. On the **Select Management Packs** page, click **Add**, and then click **Add from disk**.
4. In the **Select Management Packs to import** dialog box, select the `Amazon.AmazonWebServices.mpb` file from the location where you downloaded it, and then click **Open**.
5. On the **Select Management Packs** page, under **Import list**, select the **Amazon Web Services** management pack, and then click **Install**.

Note

System Center Operations Manager doesn't import any management packs in the **Import** list that display an **Error** icon.

6. The **Import Management Packs** page shows the progress for the import process. If a problem occurs, select the management pack in the list to view the status details. Click **Close**.

System Center 2007 R2

To install the AWS Management Pack

The management pack is distributed as a Microsoft System Installer file, `AWS-MP-Setup.msi`. It contains the required DLLs for the watcher node, root management server, and Operations console, as well as the `Amazon.AmazonWebServices.mp` file.

1. Run `AWS-MP-Setup.msi`.

Note

If your root management server, Operations console, and watcher node are on different computers, you must run the installer on each computer.

2. On the **Welcome to the Amazon Web Services Management Pack Setup Wizard** screen, click **Next**.
3. On the **End-User License Agreement** screen, read the license agreement, and, if you accept the terms, select the **I accept the terms in the License Agreement** check box, and then click **Next**.
4. On the **Custom Setup** screen, select the features you want to install, and then click **Next**.

Operations Console

Installs `Amazon.AmazonWebServices.UI.Pages.dll` and registers it in the Global Assembly Cache (GAC), and then installs `Amazon.AmazonWebServices.mp`.

Root Management Server

Installs Amazon.AmazonWebServices.Modules.dll, Amazon.AmazonWebServices.SCOM.SDK.dll and the AWS SDK for .NET (AWSSDK.dll), and then registers them in the GAC.

AWS Watcher Node

Installs Amazon.AmazonWebServices.Modules.dll and Amazon.AmazonWebServices.SCOM.SDK.dll, and then installs the AWS SDK for .NET (AWSSDK.dll) and registers it in the GAC.

5. On the **Ready to install Amazon Web Services Management Pack** screen, click **Install**.
6. On the **Completed the Amazon Web Services Management Pack Setup Wizard** screen, click **Finish**.

Note

The required DLLs are copied and registered in the GAC, and the management pack file (*.mp) is copied to the Program Files (x86)/Amazon Web Services Management Pack folder on the computer running the Operations console. Next, you must import the management pack into System Center.

7. In the Operations console, on the **Go** menu, click **Administration**, and then click **Management Packs**.
8. In the **Actions** pane, click **Import Management Packs**.
9. On the **Select Management Packs** page, click **Add**, and then click **Add from disk**.
10. In the **Select Management Packs to import** dialog box, change the directory to C:\Program Files (x86)\Amazon Web Services Management Pack, select the Amazon.AmazonWebServices.mp file, and then click **Open**.
11. On the **Select Management Packs** page, under **Import list**, select the **Amazon Web Services** management pack, and then click **Install**.

Note

System Center Operations Manager doesn't import any management packs in the **Import** list that display an **Error** icon.

12. The **Import Management Packs** page shows the progress for the import process. If a problem occurs, select the management pack in the list to view the status details. Click **Close**.

Step 2: Configure the watcher node

On System Center Operations Manager 2007 R2, the watcher node runs discoveries that go beyond the watcher node computer, so you must enable the proxy agent option on the watcher node. The proxy agent allows those discoveries to access the objects on other computers.

Note

If your system is configured with a large number of resources, we recommend that you configure one management server as a Watcher Node. Having a separate Watcher Node management server can improve performance.

If you're using System Center 2012 — Operations Manager, you can skip this step.

To enable the proxy agent on System Center Operations Manager 2007 R2

1. In the Operations console, on the **Go** menu, click **Administration**.
2. In the **Administration** workspace, under **Device Management**, click **Agent Managed**.
3. In the **Agent Managed** list, right-click the watcher node, and then click **Properties**.
4. In the **Agent Properties** dialog box, click the **Security** tab, select **Allow this agent to act as proxy and discover managed objects on other computers**, and then click **OK**.

Step 3: Create an AWS Run As account

You must set up credentials that grant AWS Management Pack access to your AWS resources.

To create an AWS Run As account

1. We recommend that you create an IAM user with the minimum access rights required (for example, the **ReadOnlyAccess** AWS managed policy works in most cases). You'll need the access keys (access key ID and secret access key) for this user to complete this procedure. For more information, see [Administering Access Keys for IAM Users](#) in the *IAM User Guide*.

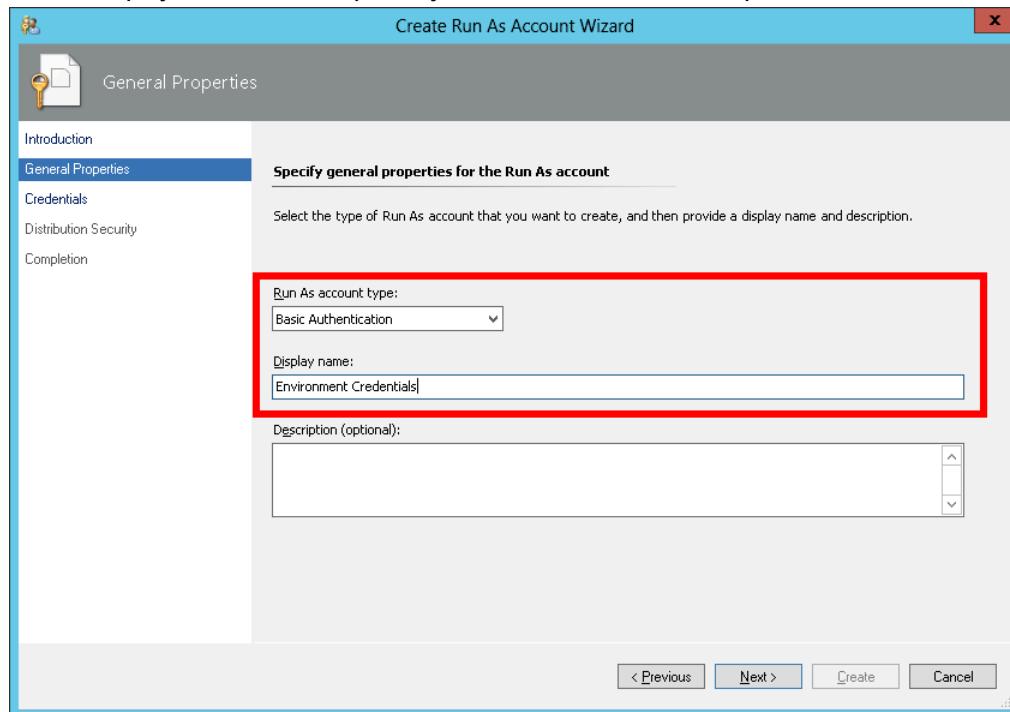

Users need programmatic access if they want to interact with AWS outside of the AWS Management Console. The way to grant programmatic access depends on the type of user that's accessing AWS.

To grant users programmatic access, choose one of the following options.

Which user needs programmatic access?	To	By
Workforce identity (Users managed in IAM Identity Center)	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	<p>Following the instructions for the interface that you want to use.</p> <ul style="list-style-type: none">• For the AWS CLI, see Configuring the AWS CLI to use AWS IAM Identity Center (successor to AWS Single Sign-On) in the <i>AWS Command Line Interface User Guide</i>.• For AWS SDKs, tools, and AWS APIs, see IAM Identity Center authentication in the <i>AWS SDKs and Tools Reference Guide</i>.
IAM	Use temporary credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	<p>Following the instructions in Using temporary credentials with AWS resources in the <i>IAM User Guide</i>.</p>
IAM	(Not recommended) Use long-term credentials to sign programmatic requests to the AWS CLI, AWS SDKs, or AWS APIs.	<p>Following the instructions for the interface that you want to use.</p> <ul style="list-style-type: none">• For the AWS CLI, see Authenticating using IAM user credentials in the <i>AWS Command Line Interface User Guide</i>.• For AWS SDKs and tools, see Authenticate using long-term credentials in the <i>AWS SDKs and Tools Reference Guide</i>.

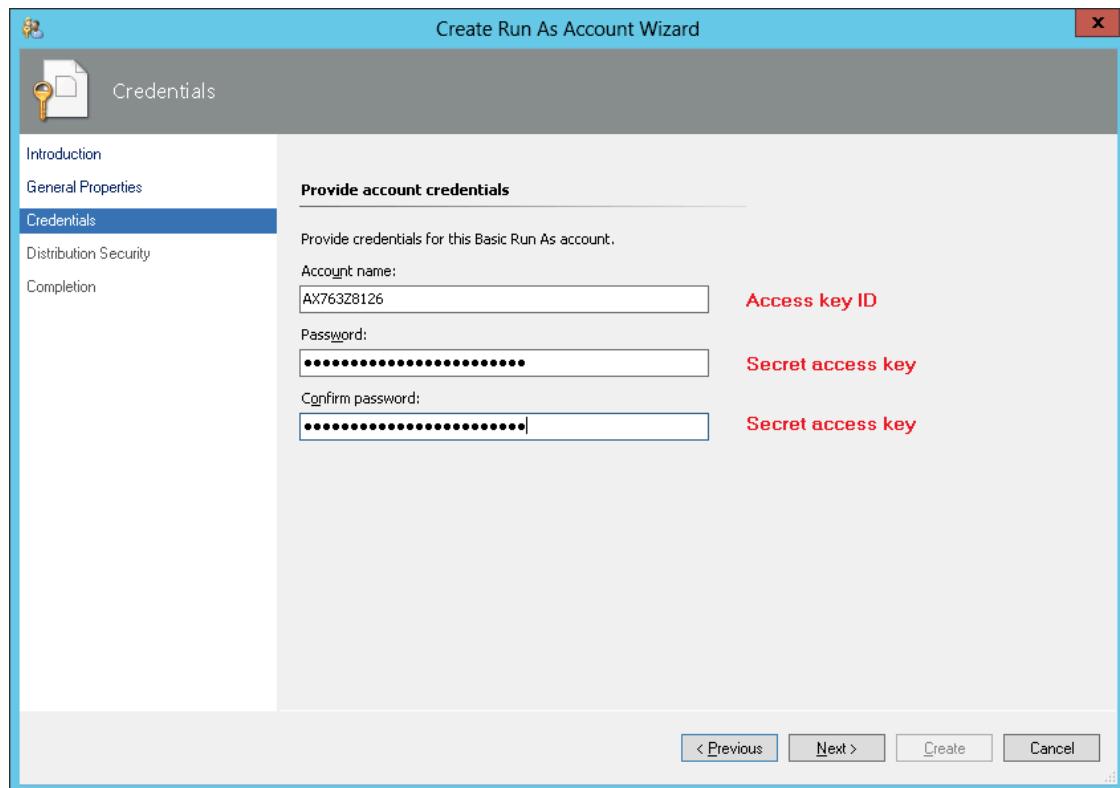

Which user needs programmatic access?	To	By
		<ul style="list-style-type: none">For AWS APIs, see Managing access keys for IAM users in the <i>IAM User Guide</i>.

2. In the Operations console, on the **Go** menu, click **Administration**.
3. In the **Administration** workspace, expand the **Run As Configuration** node, and then select **Accounts**.
4. Right-click the **Accounts** pane, and then click **Create Run As Account**.
5. In the **Create Run As Account Wizard**, on the **General Properties** page, in the **Run As account type** list, select **Basic Authentication**.
6. Enter a display name (for example, "My IAM Account") and a description, and then click **Next**.

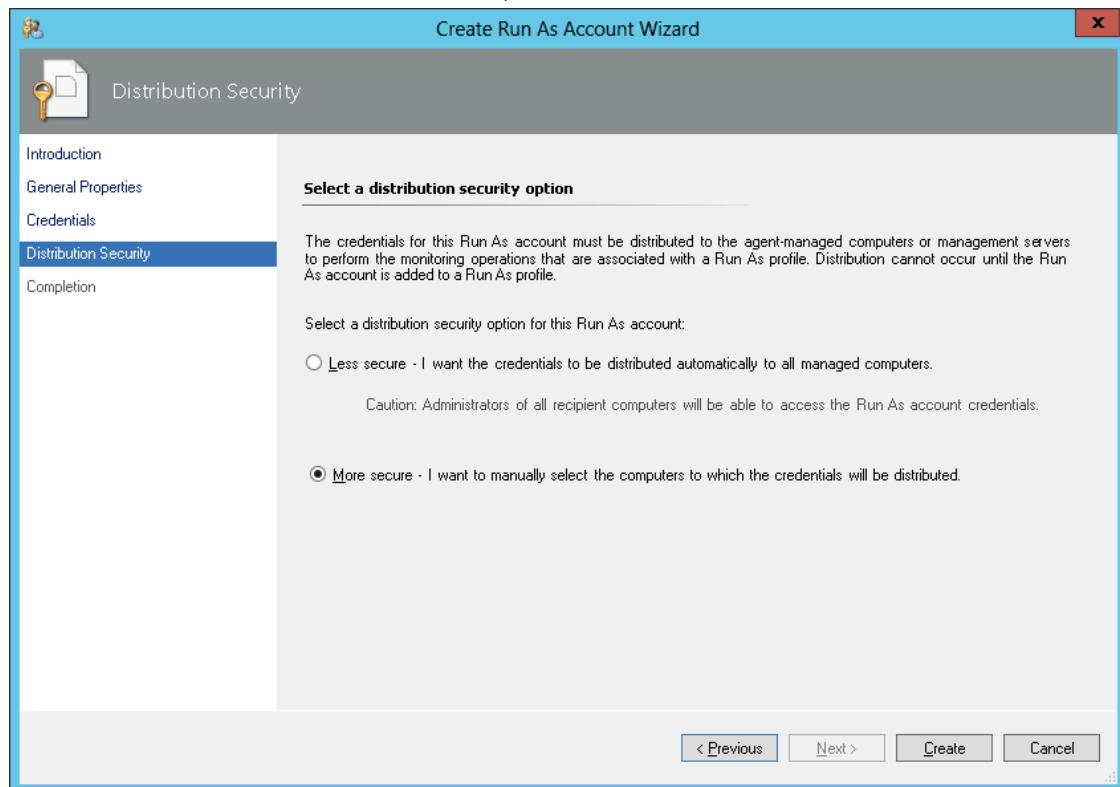

7. On the **Credentials** page, enter the access key ID in the **Account name** box and the secret access key in the **Password** box, and then click **Next**.

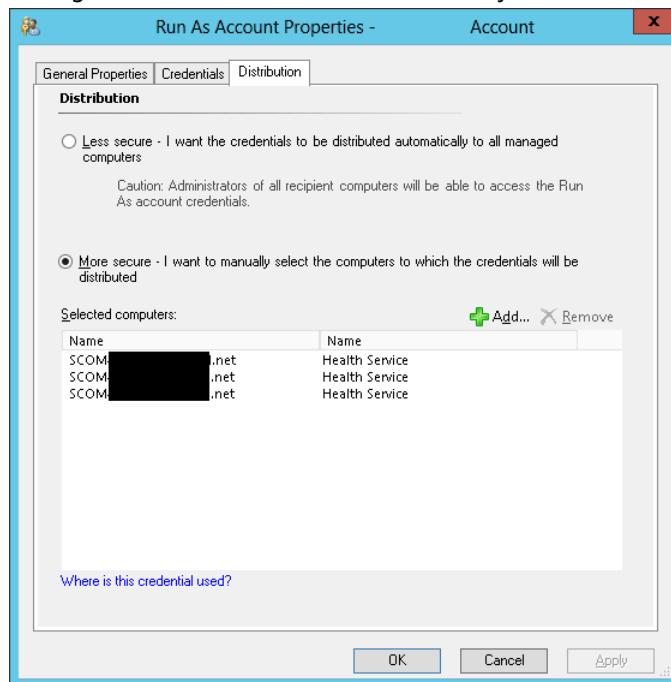

Amazon Elastic Compute Cloud
User Guide for Windows Instances
Step 3: Create an AWS Run As account

8. On the **Distribution Security** page, select **More secure - I want to manually select the computers to which the credentials will be distributed**, and then click **Create**.

9. Click **Close**.
10. In the list of accounts, select the account that you just created.
11. In the **Actions** pane, click **Properties**.
12. In the **Properties** dialog box, verify that the **More Secure** option is selected and that all management servers to be used to monitor your AWS resources are listed.

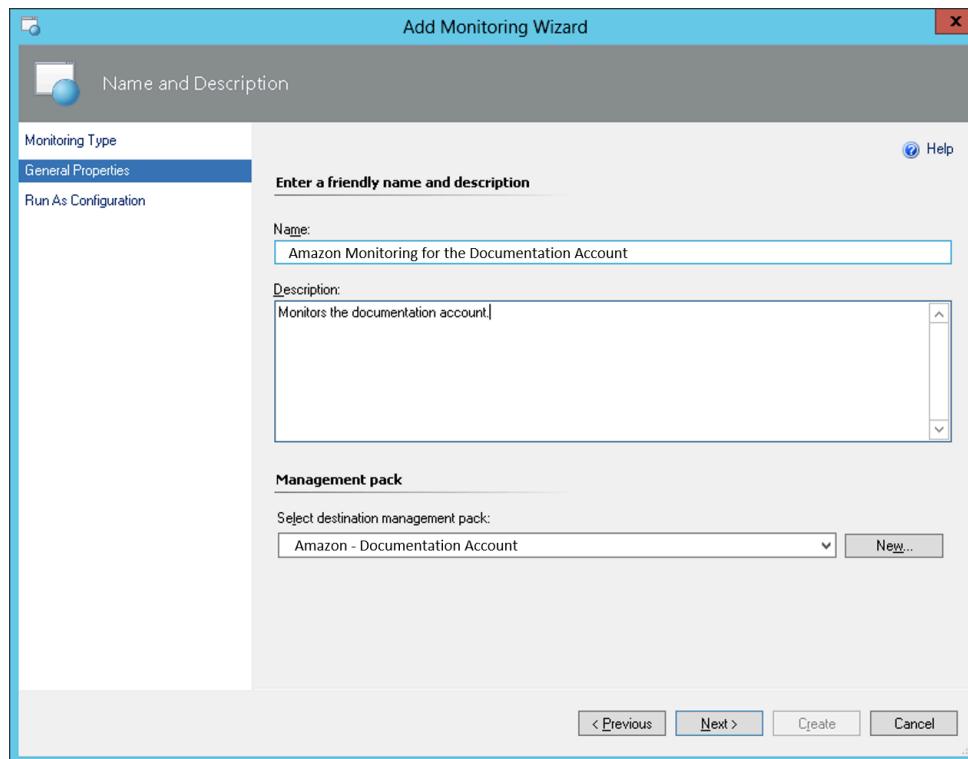

Step 4: Run the Add Monitoring wizard

You can configure the AWS Management Pack to monitor a particular AWS account by using the Add Monitoring Wizard, which is available in the **Authoring** workspace of the Operations console. This wizard creates a management pack that contains the settings for the AWS account to monitor. You must run this wizard to monitor each AWS account. For example, if you want to monitor two AWS accounts, you must run the wizard twice.

System Center 2012

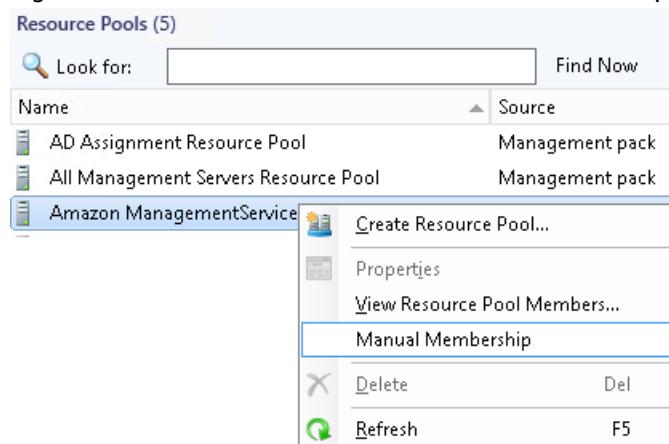

To run the Add Monitoring Wizard on System Center 2012 — Operations Manager

1. In the Operations console, on the **Go** menu, click **Authoring**.
2. In the **Authoring** workspace, expand the **Management Pack Templates** node, right-click **Amazon Web Services**, and then click **Add Monitoring Wizard**.
3. In the **Add Monitoring Wizard**, in the **Select the monitoring type** list, select **Amazon Web Services**, and then click **Next**.
4. On the **General Properties** page, in the **Name** box, enter a name (for example, "My AWS Resources"). In the **Description** box, enter a description.
5. In the **Select destination management pack** list, select an existing management pack (or click **New** to create one) where you want to save the settings. Click **Next**.

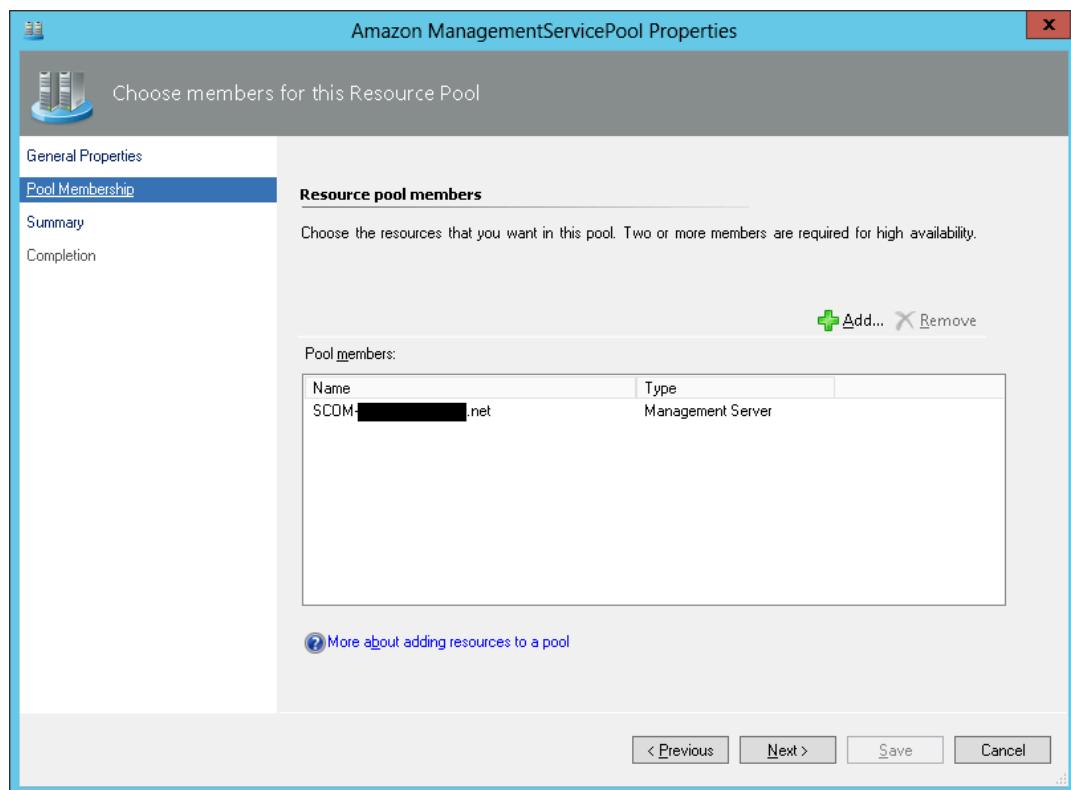

By default, when you create a management pack object, disable a rule or monitor, or create an override, Operations Manager saves the setting to the default management pack. As a best practice, you should create a separate management pack for each sealed management pack that you want to customize, instead of saving your customized settings to the default management pack.

6. The AWS Management Pack automatically creates a resource pool and adds the management servers to it. To control server membership, make the following changes:
 - a. Click **Administration** on the **Go** menu.
 - b. Click the **Resource Pools** node.
 - c. Right-click the **AWS Resource Pool** in the **Resource Pools** pane and select **Manual Membership**.

- d. Right-click the **AWS Resource Pool** in the **Resource Pools** pane and select **Properties**.
- e. On the **Pool Membership** page, remove the management servers that should not monitor AWS resources.

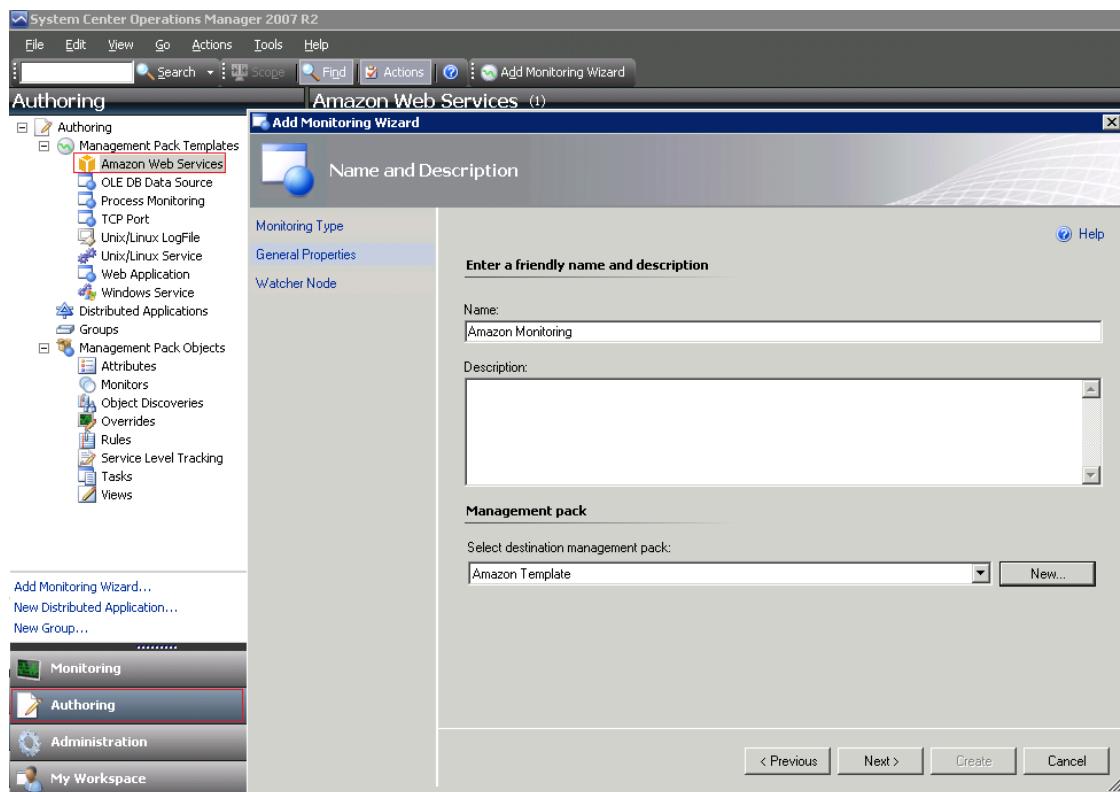

- After the AWS Management Pack is configured, it shows up as a sub-folder of the Amazon Web Services folder in the **Monitoring** workspace of the Operations console.

System Center 2007 R2

To run the Add Monitoring Wizard on System Center Operations Manager 2007

- In the Operations console, on the **Go** menu, click **Authoring**.
- In the **Authoring** workspace, expand the **Management Pack Templates** node, right-click **Amazon Web Services**, and then click **Add Monitoring Wizard**.
- In the **Add Monitoring Wizard**, in the **Select the monitoring type list**, select **Amazon Web Services**, and then click **Next**.
- On the **General Properties** page, in the **Name** box, enter a name (for example, "My AWS Resources"). In the **Description** box, enter a description.
- In the **Select destination management pack** drop-down list, select an existing management pack (or click **New** to create a new one) where you want to save the settings. Click **Next**.

Amazon Elastic Compute Cloud
User Guide for Windows Instances
Step 4: Run the Add Monitoring wizard

By default, when you create a management pack object, disable a rule or monitor, or create an override, Operations Manager saves the setting to the default management pack. As a best practice, you should create a separate management pack for each sealed management pack that you want to customize, instead of saving your customized settings to the default management pack.

6. On the **Watcher Node Configuration** page, in the **Watcher Node** list, select an agent-managed computer to act as the watcher node.
7. In the **Select AWS Run As account** drop-down list, select the Run As account that you created earlier, and then click **Create**.
8. After the AWS Management Pack is configured, it first discovers the watcher node. To verify that the watcher node was discovered successfully, navigate to the **Monitoring** workspace in the Operations console. You should see a new Amazon Web Services folder and an Amazon Watcher Nodes subfolder under it. This subfolder displays the watcher nodes. The AWS Management Pack automatically checks and monitors the watcher node connectivity to AWS. When the watcher node is discovered, it shows up in this list. When the watcher node is ready, its state changes to Healthy.

Note

To establish connectivity with AWS, the AWS Management Pack requires that you deploy the AWS SDK for .NET, modules, and scripts to the watcher node. This can take about ten minutes. If the watcher node doesn't appear, or if you see the state as Not Monitored, verify your Internet connectivity and IAM permissions. For more information, see [Troubleshoot the AWS Management Pack \(p. 2236\)](#).

9. After the watcher node is discovered, dependent discoveries are triggered, and the AWS resources are added to the **Monitoring** workspace of the Operations console.

The discovery of AWS resources should finish within twenty minutes. This process can take more time, based on your Operations Manager environment, your AWS environment, the load on the management server, and the load on the watcher node. For more information, see [Troubleshoot the AWS Management Pack \(p. 2236\)](#).

Step 5: Configure ports and endpoints

The AWS Management Pack for Microsoft System Center must be able to communicate with AWS services to monitor the performance of those services and provide alerts in System Center. For monitoring to succeed, you must configure outbound access on the Management Pack servers to allow access to the AWS endpoints for the following services. To configure outbound access from your instances, see [Amazon EC2 security groups for Windows instances](#).

This enables monitoring for the following AWS services:

- Amazon Elastic Compute Cloud (EC2)
- Elastic Load Balancing
- Amazon EC2 Auto Scaling
- AWS Elastic Beanstalk
- Amazon CloudWatch
- AWS CloudFormation

The AWS Management Pack uses the public APIs in the AWS SDK for .NET to retrieve information from these services. Log on to each server and enable outbound firewall rules to allow access to the AWS endpoints.

If your firewall application supports more detailed settings, you can configure specific endpoints for each service. An endpoint is a URL that is the entry point for a web service. For example, ec2.us-west-2.amazonaws.com is an entry point for the Amazon EC2 service. To configure endpoints on your firewall, [locate the specific endpoint URLs](#) for the AWS services you are running and specify those endpoints in your firewall application.

Use the AWS Management Pack

You can use the AWS Management Pack to monitor the health of your AWS resources.

Contents

- [Views \(p. 2220\)](#)
- [Discoveries \(p. 2229\)](#)
- [Monitors \(p. 2230\)](#)
- [Rules \(p. 2231\)](#)
- [Events \(p. 2231\)](#)
- [Health model \(p. 2232\)](#)
- [Customize the AWS Management Pack \(p. 2234\)](#)

Views

The AWS Management Pack provides the following views, which are displayed in the **Monitoring** workspace of the Operations console.

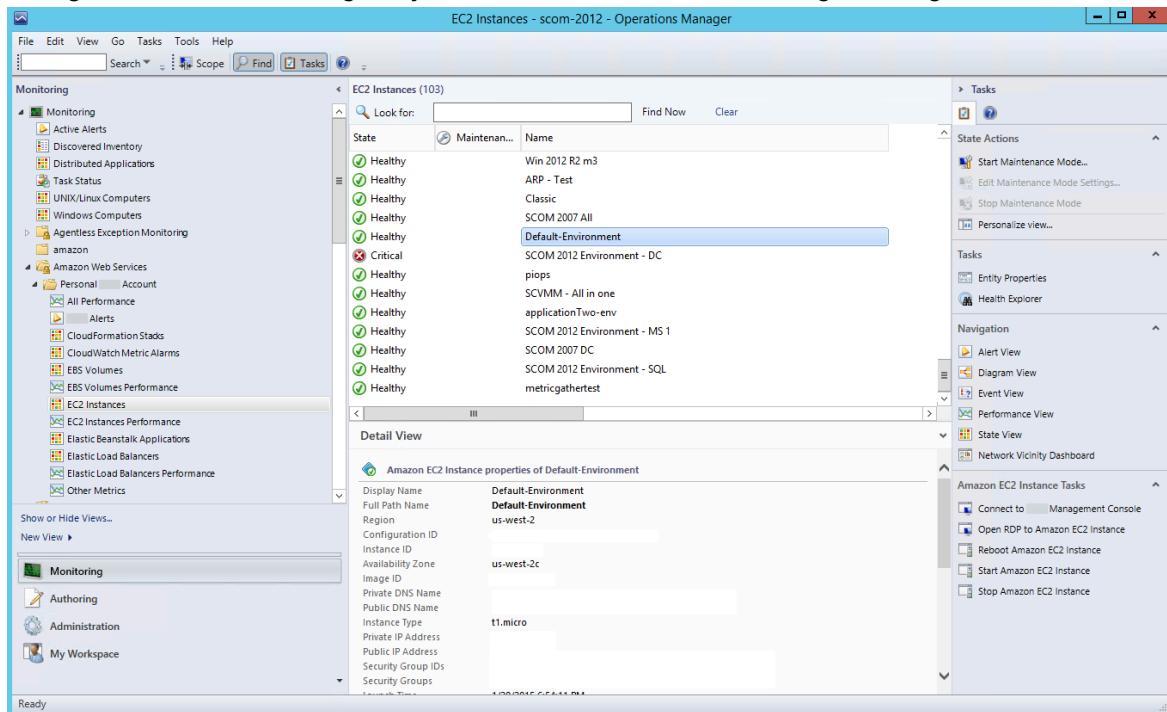

Views

- [EC2 Instances \(p. 2221\)](#)

- [Amazon EBS Volumes \(p. 2222\)](#)
- [Classic Load Balancers \(p. 2223\)](#)
- [AWS Elastic Beanstalk applications \(p. 2224\)](#)
- [AWS CloudFormation stacks \(p. 2225\)](#)
- [Amazon performance views \(p. 2227\)](#)
- [Amazon CloudWatch metric alarms \(p. 2227\)](#)
- [AWS alerts \(p. 2228\)](#)
- [Watcher nodes \(System Center Operations Manager 2007 R2\) \(p. 2229\)](#)

EC2 Instances

View the health state of the EC2 instances for a particular AWS account, from all Availability Zones and Regions. The view also includes EC2 instances running in a virtual private cloud (VPC). The AWS Management Pack retrieves tags, so you can search and filter the list using those tags.

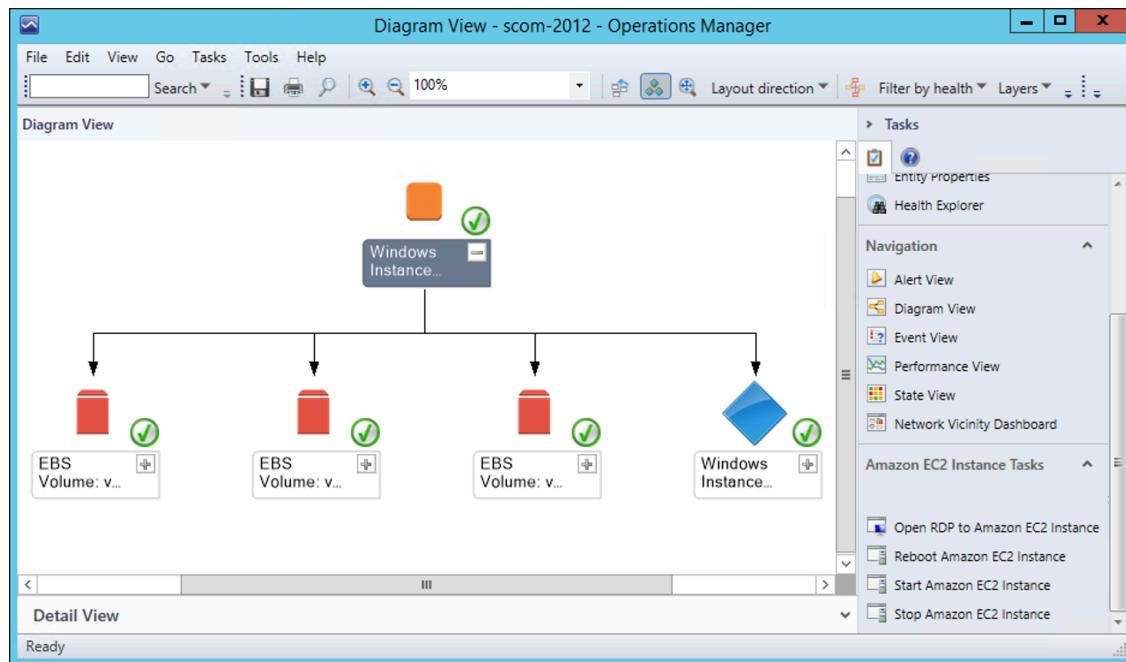

When you select an Amazon EC2 instance, you can perform instance health tasks:

- **Open Amazon Console:** Launches the AWS Management Console in a web browser.
- **Open RDP to Amazon EC2 Instance:** Opens an RDP connection to the selected Windows instance.
- **Reboot Amazon EC2 Instance:** Reboots the selected EC2 instance.
- **Start Amazon EC2 Instance:** Starts the selected EC2 instance.
- **Stop Amazon EC2 Instance:** Stops the selected EC2 instance.

EC2 Instances Diagram View

Shows the relationship of an instance with other components.

Amazon Elastic Compute Cloud User Guide for Windows Instances Views

Amazon EBS Volumes

Shows the health state of all the Amazon EBS volumes for a particular AWS account from all Availability Zones and Regions.

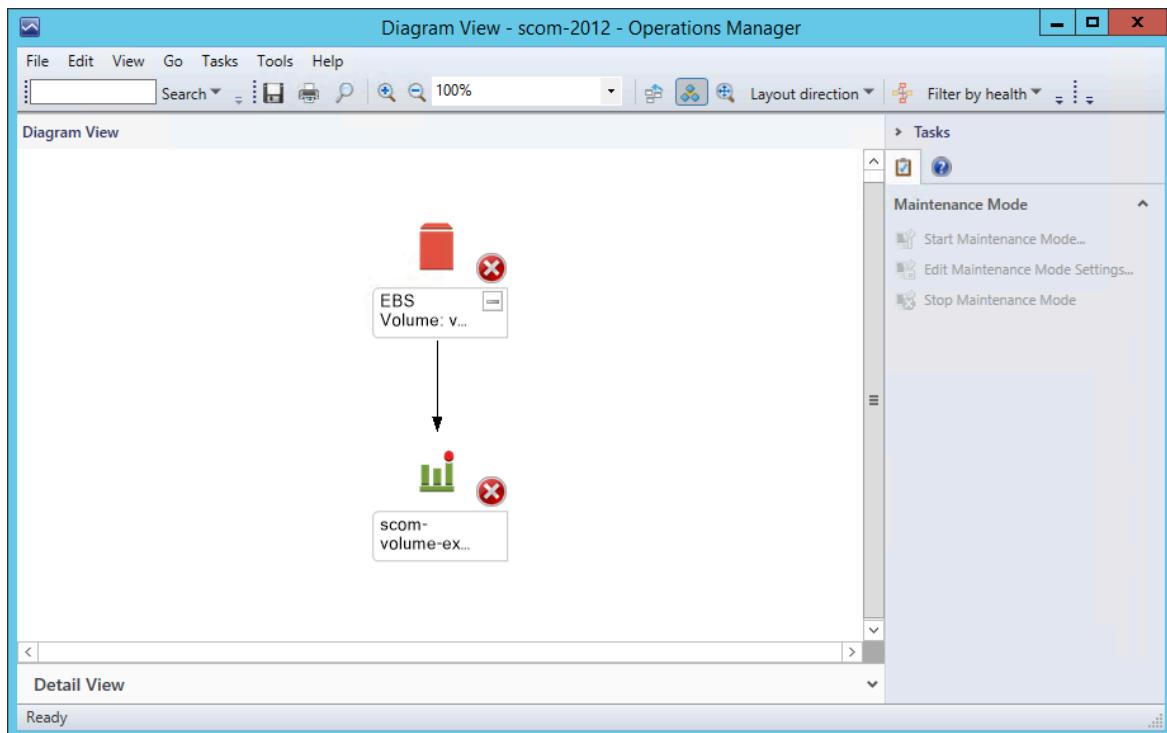

The screenshot shows the 'EBS Volumes' view in SCOM. On the left, the navigation pane is expanded to show categories like 'Monitoring', 'Active Alerts', 'Discovered Inventory', and 'Amazon Web Services'. In the center, a table lists 214 EBS volumes. The columns include State (with categories like 'Critical', 'Maintenance', 'Healthy'), Display Name, Volume ID, Availability Zone, Size, and Create Time. The 'State' column is currently sorted by 'Critical'. The 'Tasks' pane on the right provides options for managing the volumes, such as 'Start Maintenance Mode...', 'Edit Maintenance Mode Settings...', and 'Stop Maintenance Mode'. The 'Detail View' pane at the bottom shows the properties of a selected volume, including its display name, full path, region, volume ID, account guid, availability zone, size, IOPS, attachments, snapshot ID, volume type (gp2), and creation time.

State	Display Name	Volume ID	Availability Zone	Size	Create Time
Critical	EBS Volume v...		us-west-2b	200	1/19/2015 6:35...
Maintenance	regedit volume		us-east-1c	30	8/22/2014 7:16...
Healthy	EBS Volume v...		us-east-1c	100	8/22/2014 5:19...
Healthy	EBS Volume v...		eu-west-1a	30	8/29/2014 9:08...
Healthy	EBS Volume v...		ap-southeast-2a	150	8/22/2014 6:06...
Healthy	EBS Volume v...		us-west-2a	250	3/2/2015 8:07:5...
Healthy	EBS Volume v...		ap-southeast-2b	10	1/11/2015 12:5...
Healthy	EBS Volume v...		eu-west-1c	10	1/19/2015 11:2...
Healthy	reboot loop vol...		eu-west-1a	80	8/28/2014 10:0...
Healthy	EBS Volume v...		us-west-2c	75	8/23/2014 11:1...
Healthy	EBS Volume v...		ap-southeast-2a	30	8/29/2014 12:2...
Healthy	EBS Volume v...		us-east-1c	30	8/28/2014 11:1...
Healthy	EBS Volume v...		us-east-1b	100	8/23/2014 3:29...
Healthy	EBS Volume v...		eu-west-1a	100	8/29/2014 9:07...

Amazon EBS Volumes Diagram View

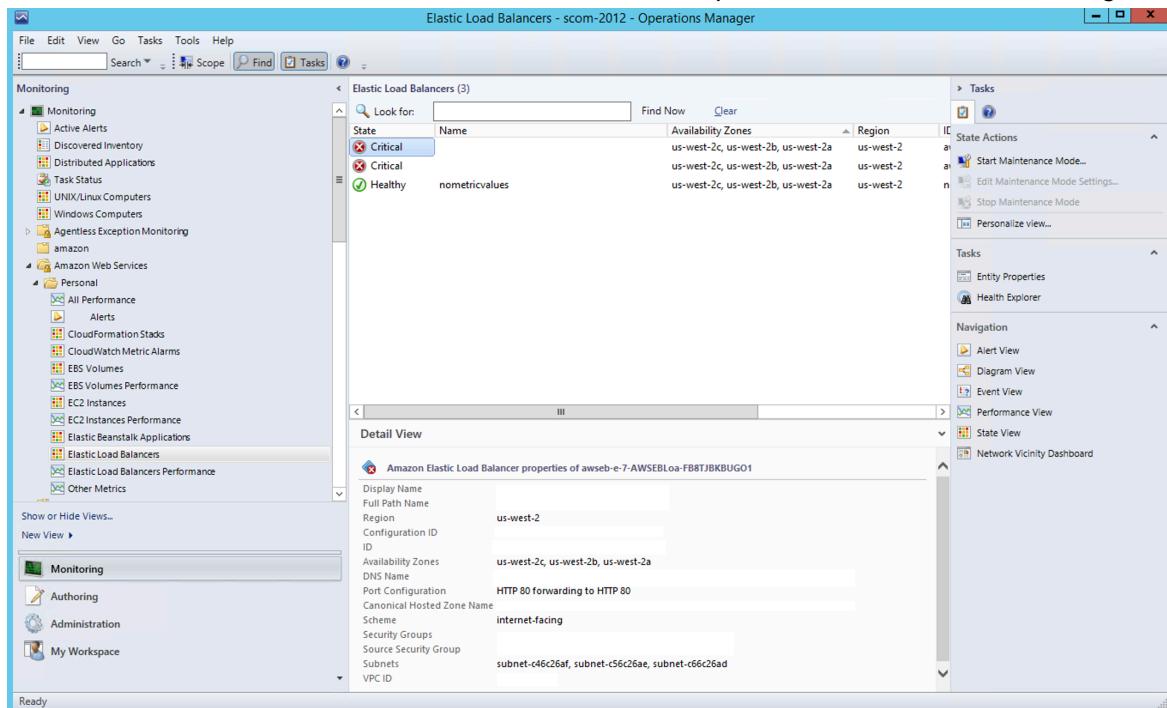

Shows an Amazon EBS volume and any associated alarms. The following illustration shows an example:

**Amazon Elastic Compute Cloud
User Guide for Windows Instances
Views**

Classic Load Balancers

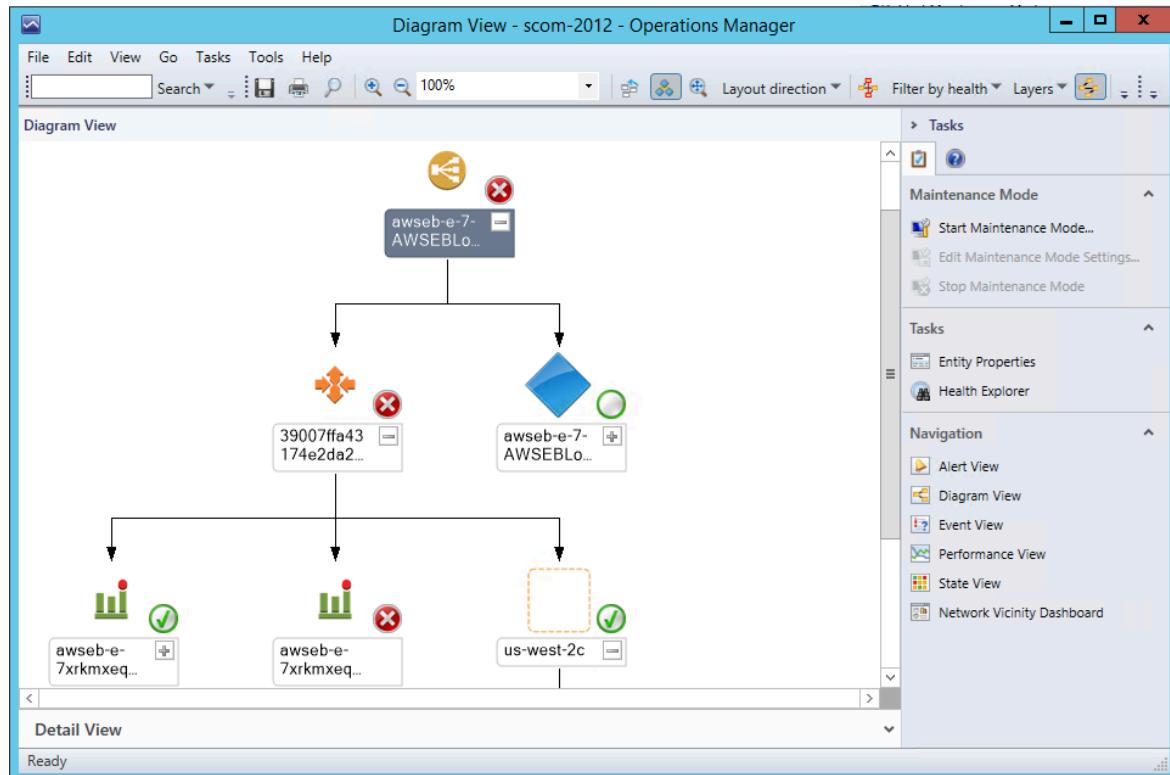

Shows the health state of all of the Classic Load Balancers for a particular AWS account from all Regions.

Elastic Load Balancing Diagram View

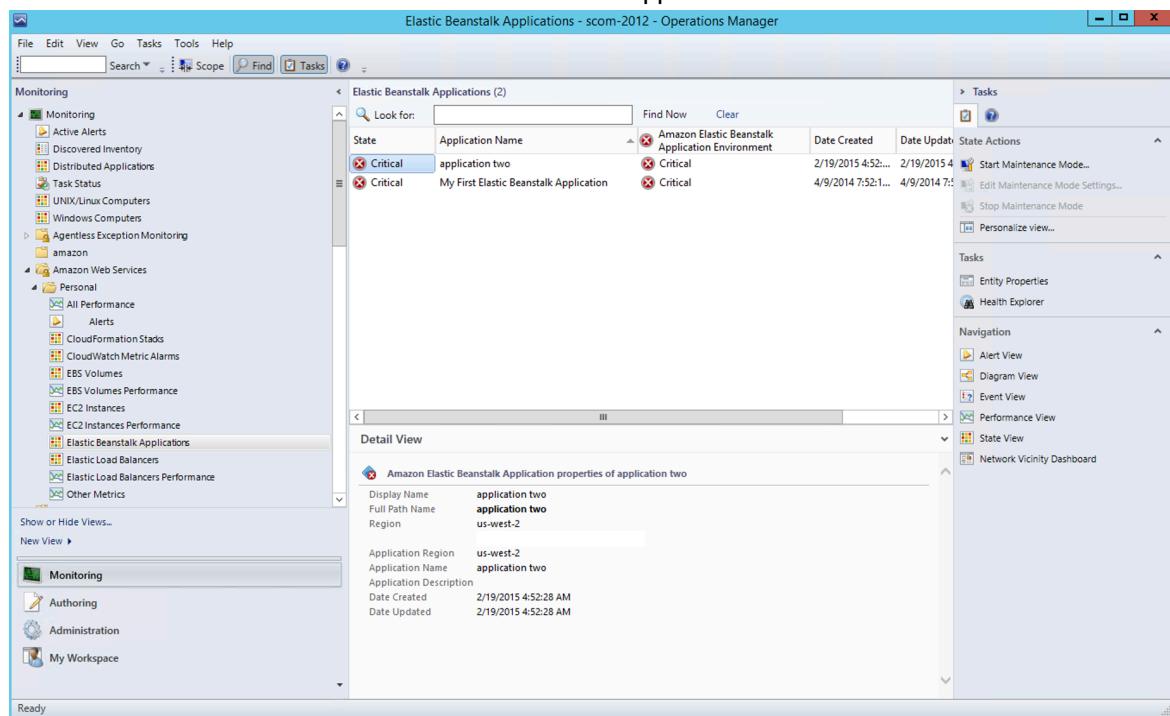

Amazon Elastic Compute Cloud User Guide for Windows Instances Views

Shows the Elastic Load Balancing relationship with other components. The following illustration shows an example:

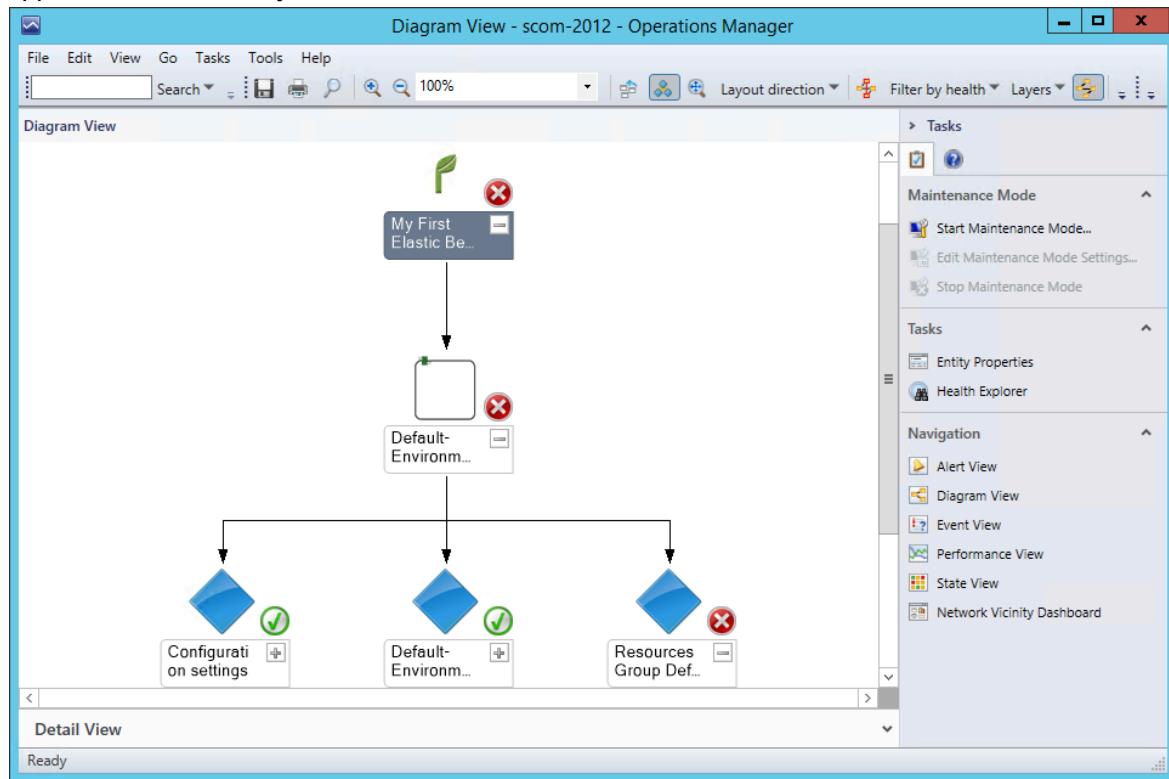

AWS Elastic Beanstalk applications

Shows the state of all discovered AWS Elastic Beanstalk applications.

AWS Elastic Beanstalk Applications Diagram View

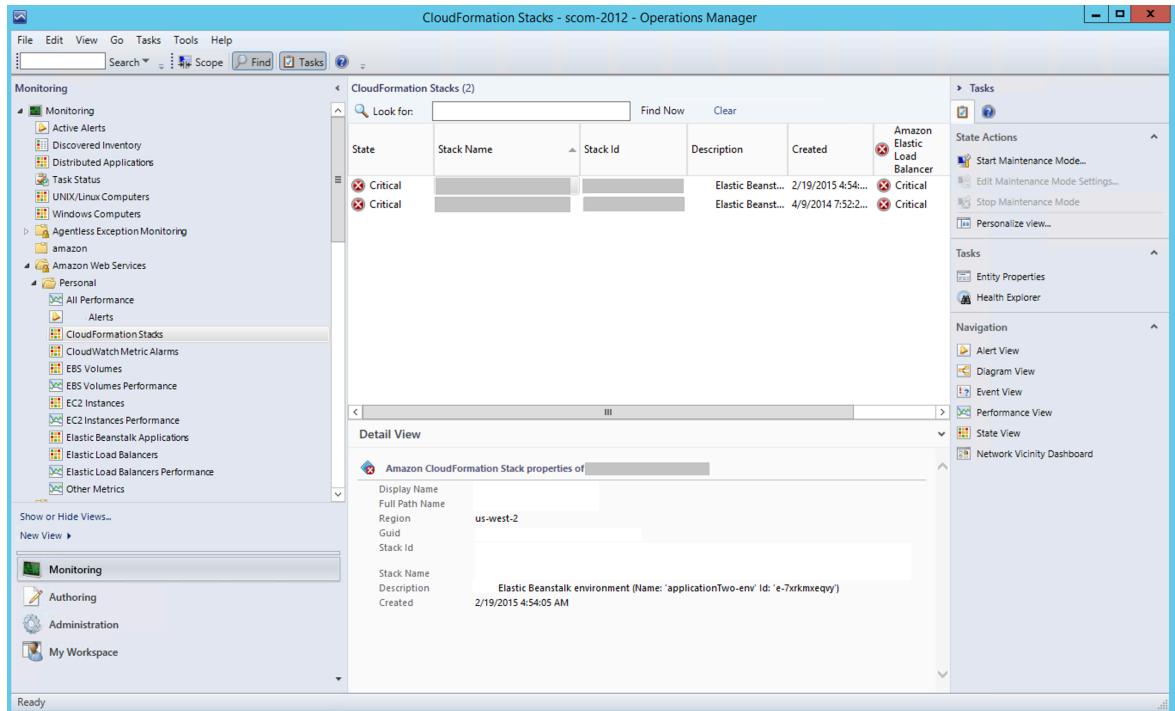

Shows the AWS Elastic Beanstalk application, application environment, application configuration, and application resources objects.

AWS CloudFormation stacks

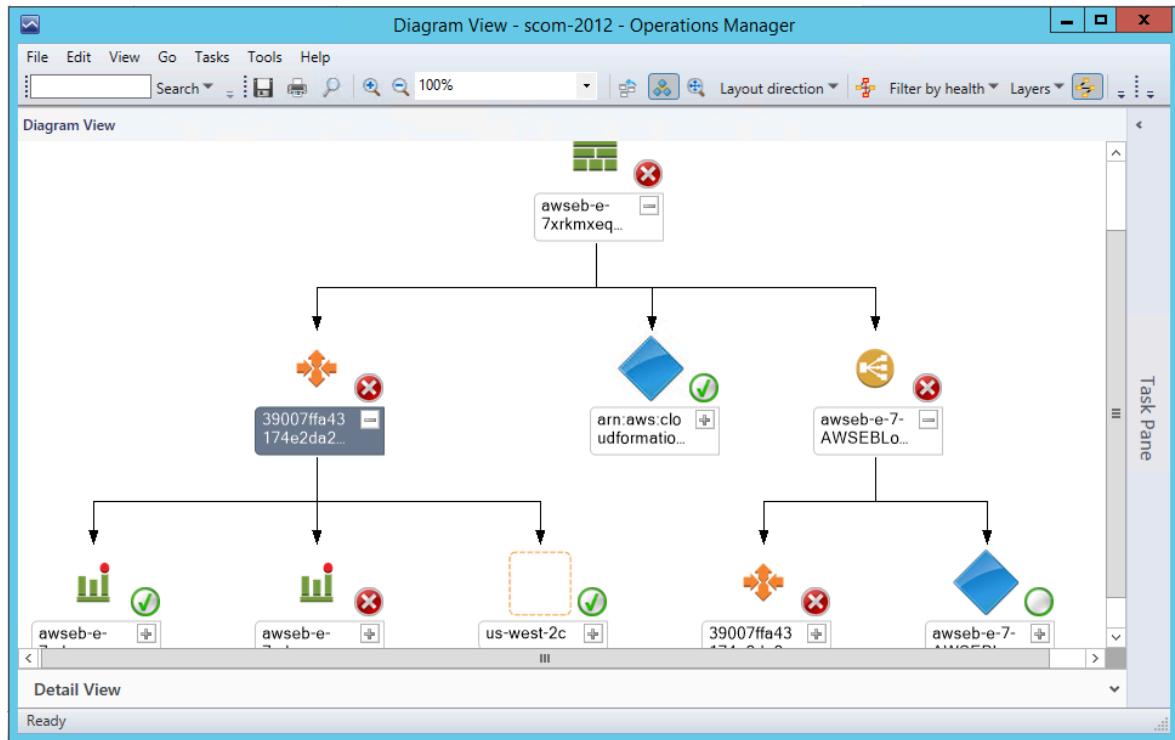

Shows the health state of all the AWS CloudFormation stacks for a particular AWS account from all Regions.

Amazon Elastic Compute Cloud User Guide for Windows Instances Views

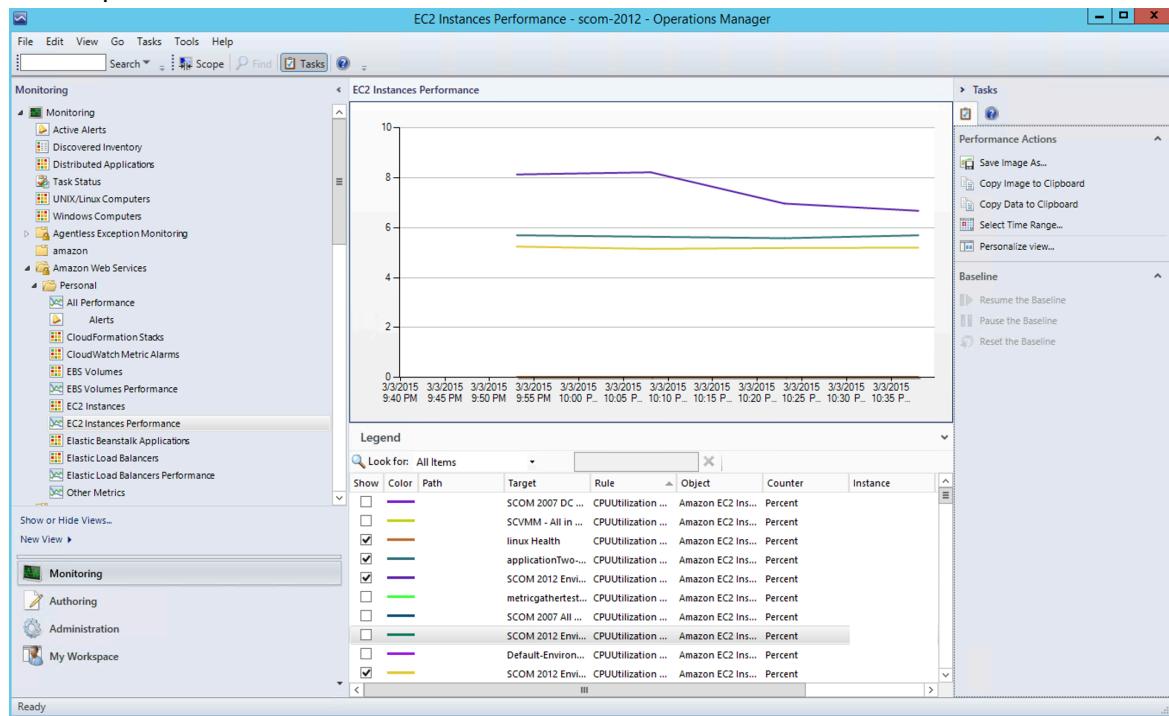

AWS CloudFormation stacks diagram view

Shows the AWS CloudFormation stack relationship with other components. An AWS CloudFormation stack might contain Amazon EC2 or Elastic Load Balancing resources. The following illustration shows an example:

Amazon performance views

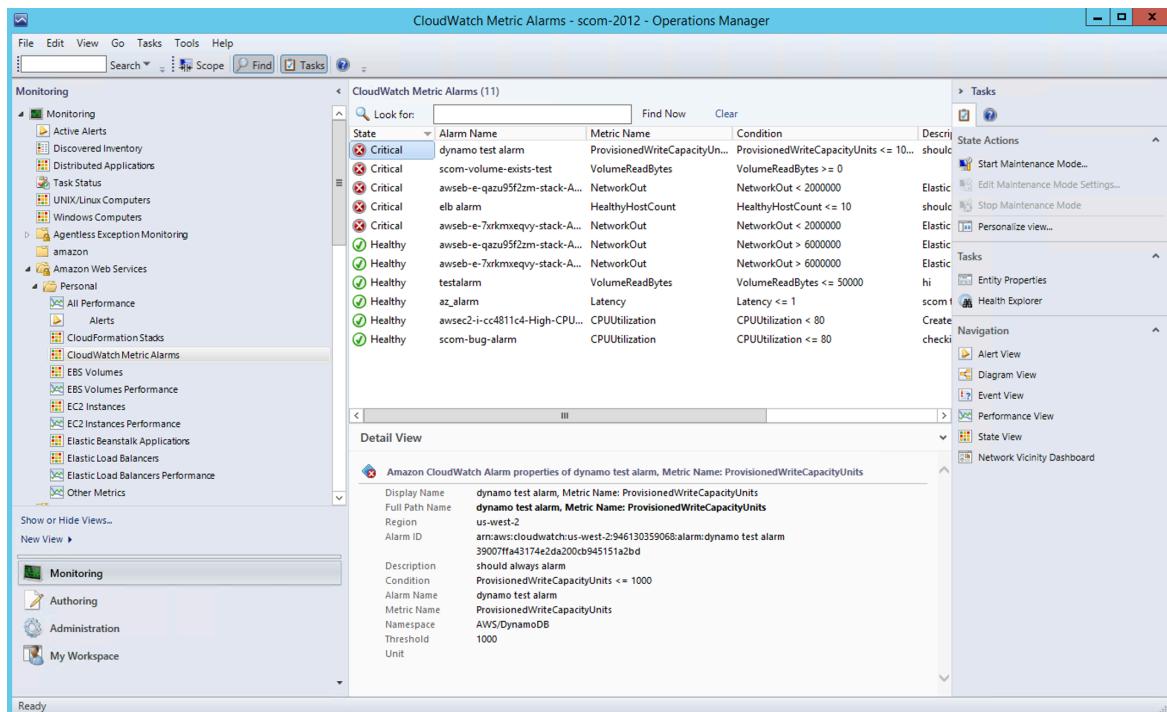

Shows the Amazon CloudWatch metrics for Amazon EC2, Amazon EBS, and Elastic Load Balancing, custom metrics, and metrics created from CloudWatch alarms. In addition, there are separate performance views for each resource. The **Other Metrics** performance view contains custom metrics, and metrics created from CloudWatch alarms. For more information about these metrics, see [AWS Services That Publish CloudWatch Metrics](#) in the *Amazon CloudWatch User Guide*. The following illustration shows an example.

Amazon CloudWatch metric alarms

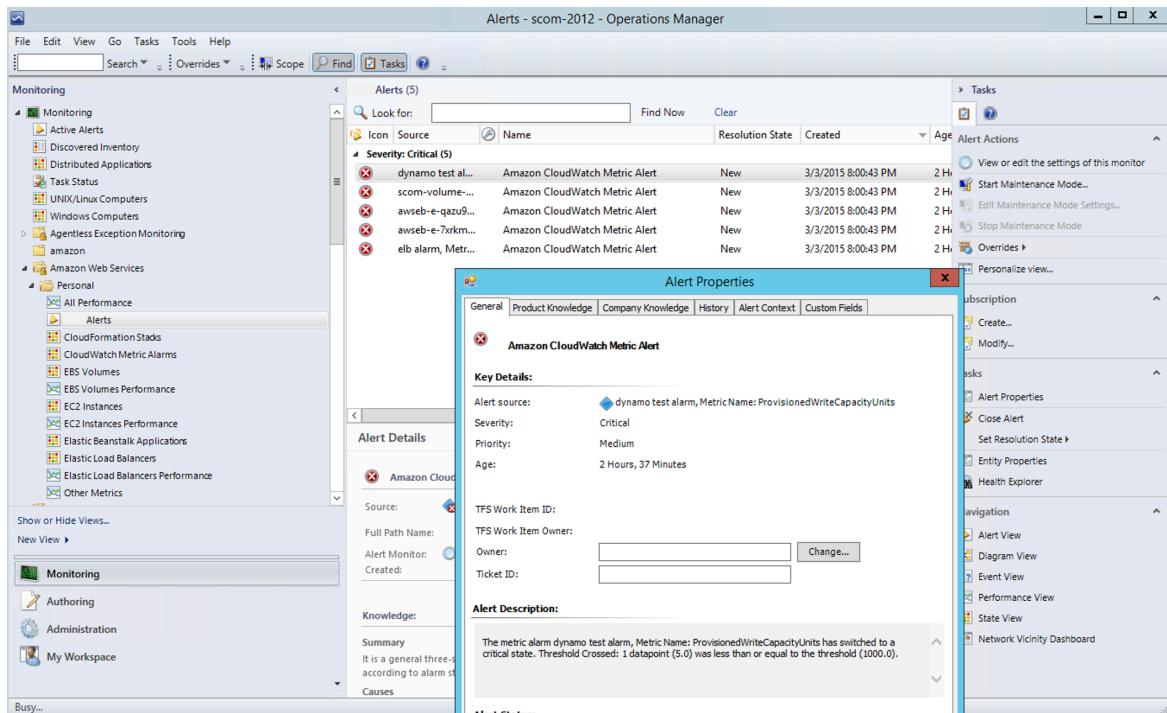

Shows Amazon CloudWatch alarms related to the discovered AWS resources.

Amazon Elastic Compute Cloud User Guide for Windows Instances Views

AWS alerts

Shows the alerts that the AWS management pack produces when the health of an object is in a critical state.

Watcher nodes (System Center Operations Manager 2007 R2)

View the health state of the watcher nodes across all of the AWS accounts that are being monitored. A **Healthy** state means that the watcher node is configured correctly and can communicate with AWS.

The screenshot shows the 'Administration' interface of System Center Operations Manager 2007 R2. The left pane is a tree view of management categories. Under 'Device Management', the 'Agent Managed' node is selected, which is further expanded to show 'Agentless Managed', 'Management Servers', 'Network Devices', 'Pending Management', 'Unix/Linux Servers', 'Management Packs', 'Notifications', 'Product Connectors', 'Run As Configuration', 'Security', and 'User Roles'. The right pane displays a list titled 'Agent Managed (1)'. It includes a search bar ('Look for:'), two columns ('Health State' and 'FQDN'), and a single item: 'Primary Management Server' with a status of 'Healthy' and FQDN 'WIN-EWGY9OC'.

Discoveries

Discoveries are the AWS resources that are monitored by the AWS Management Pack. The AWS Management Pack discovers the following objects:

- Amazon EC2 instances
- EBS volumes
- ELB load balancers
- AWS CloudFormation stacks
- Amazon CloudWatch alarms
- AWS Elastic Beanstalk applications
- Amazon EC2 Auto Scaling groups and Availability Zones

Amazon CloudWatch metrics are generated for the following resources:

- Amazon EC2 instance
- EBS volume
- Elastic Load Balancing
- Custom Amazon CloudWatch metrics
- Metrics from existing Amazon CloudWatch alarms

For Amazon CloudWatch metrics discovery, the following guidelines apply:

- AWS CloudFormation stacks do not have any default Amazon CloudWatch metrics.
- Stopped Amazon EC2 instances or unused Amazon EBS volumes do not generate data for their default Amazon CloudWatch metrics.

- After starting an Amazon EC2 instance, it can take up to 30 minutes for the Amazon CloudWatch metrics to appear in Operations Manager.
- Amazon CloudWatch retains the monitoring data for two weeks, even if your AWS resources have been terminated. This data appears in Operations Manager.
- An existing Amazon CloudWatch alarm for a resource that is not supported will create a metric and be associated with the Amazon CloudWatch alarm. These metric can be viewed in the Other Metrics performance view.

The AWS Management Pack also discovers the following relationships:

- AWS CloudFormation stack and its Elastic Load Balancing or Amazon EC2 resources
- Elastic Load Balancing load balancer and its EC2 instances
- Amazon EC2 instance and its EBS volumes
- Amazon EC2 instance and its operating system
- AWS Elastic Beanstalk application and its environment, configuration, and resources

The AWS Management Pack automatically discovers the relationship between an EC2 instance and the operating system running on it. To discover this relationship, the Operations Manager Agent must be installed and configured on the instance and the corresponding operating system management pack must be imported in Operations Manager.

Discoveries run on the management servers in the resource pool (System Center 2012) or the watcher node (System Center 2007 R2).

Discovery	Interval (seconds)
Amazon Resources Discovery (SCOM 2012) Discovers EC2 instances, Amazon EBS volumes, load balancers, and CloudFront stacks.	14400
AWS Elastic Beanstalk Discovery Discovers AWS Elastic Beanstalk and its relationship with environment, resources, and configuration.	14400
CloudWatch Alarms Discovery Discovers alarms generated using CloudWatch metrics.	900
Custom CloudWatch Metric Discovery Discovers custom CloudWatch metrics.	14400
Watcher Node Discovery (SCOM 2007 R2) Targets the root management server and creates the watcher node objects.	14400

Monitors

Monitors are used to measure the health of your AWS resources. Monitors run on the management servers in the resource pool (System Center 2012) or the watcher node (System Center 2007 R2).

Monitor	Interval (seconds)
AWS CloudFormation Stack Status	900
Amazon CloudWatch Metric Alarm	300
Amazon EBS Volume Status	900
Amazon EC2 Instance Status	900
Amazon EC2 Instance System Status	900
AWS Elastic Beanstalk Status	900
Watcher Node to Amazon Cloud Connectivity (SCOM 2007 R2)	900

Rules

Rules create alerts (based on Amazon CloudWatch metrics) and collect data for analysis and reporting.

Rule	Interval (seconds)
AWS Resource Discovery Rule (SCOM 2007 R2) Targets the watcher node and uses the AWS API to discover objects for the following AWS resources: EC2 instances, EBS volumes, load balancers, and AWS CloudFormation stacks. (CloudWatch metrics or alarms are not discovered). After discovery is complete, view the objects in the Not Monitored state.	14400
Amazon Elastic Block Store Volume Performance Metrics Data Collection Rule	900
Amazon EC2 Instance Performance Metrics Data Collection Rule	900
Elastic Load Balancing Balancing Performance Metrics Data Collection Rule	900
Custom CloudWatch Metric Data Collection Rule	900

Events

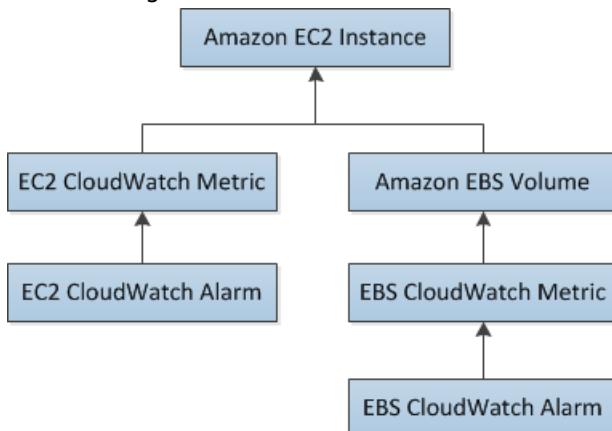

Events report on activities that involve the monitored resources. Events are written to the Operations Manager event log.

Event ID	Description
4101	Amazon EC2 Instance Discovery (General Discovery) finished
4102	Elastic Load Balancing Metrics Discovery, Amazon EBS Volume Metrics Discovery, Amazon EC2 Instance Metrics Discovery finished
4103	Amazon CloudWatch Metric Alarms Discovery finished

Event ID	Description
4104	Amazon Windows Computer Discovery finished
4105	Collecting Amazon Metrics Alarm finished
4106	EC2 Instance Computer Relation Discovery finished
4107	Collecting AWS CloudFormation Stack State finished
4108	Collecting Watcher Node Availability State finished
4109	Amazon Metrics Collection Rule finished
4110	Task to change Amazon Instance State finished
4111	EC2 Instance Status Monitor State finished
4112	Amazon EBS Volume Status Monitor State finished
4113	Amazon EC2 Instance Scheduled Events Monitor State calculated
4114	Amazon EBS Scheduled Events Monitor State calculated
4115	Elastic Beanstalk Discovery finished
4116	Elastic Beanstalk Environment Status State calculated
4117	Elastic Beanstalk Environment Operational State calculated
4118	Elastic Beanstalk Environment Configuration State calculated

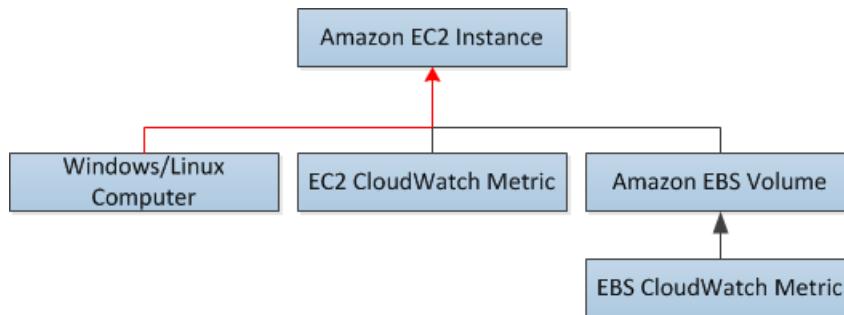

Health model

The following illustration shows the health model defined by the AWS Management Pack.

The health state for a CloudWatch alarm is rolled up to its corresponding CloudWatch metric. The health state for a CloudWatch metric for Amazon EC2 is rolled up to the EC2 instance. Similarly, the health state for the CloudWatch metrics for Amazon EBS is rolled up to the Amazon EBS volume. The health states for the Amazon EBS volumes used by an EC2 instance are rolled up to the EC2 instance.

When the relationship between an EC2 instance and its operating system has been discovered, the operating system health state is rolled up to the EC2 instance.

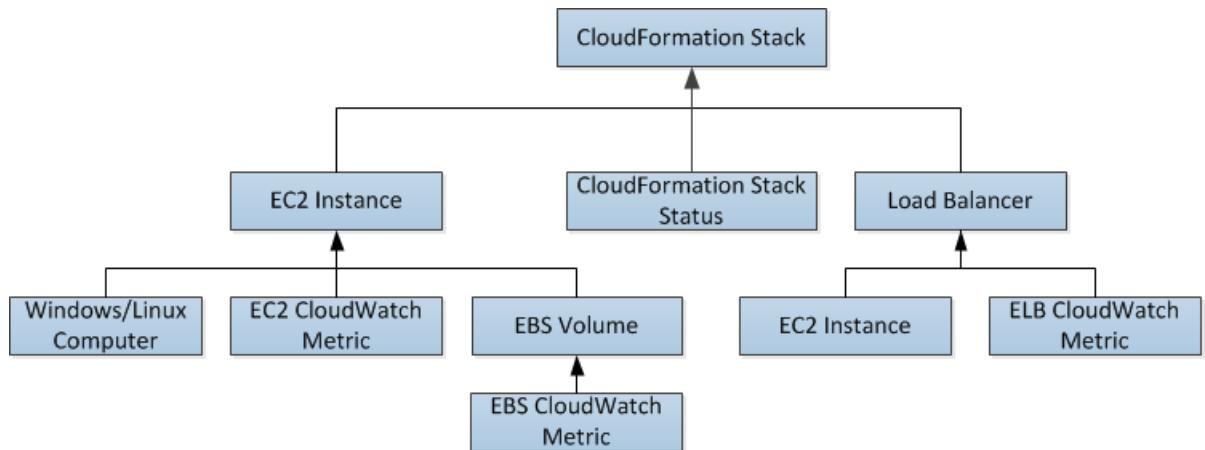

The health state of an AWS CloudFormation stack depends on the status of the AWS CloudFormation stack itself and the health states of its resources, namely the load balancers and EC2 instances.

The following table illustrates how the status of the AWS CloudFormation stack corresponds to its health state.

Health State	AWS CloudFormation Stack Status	Notes
Error	CREATE_FAILED DELETE_IN_PROGRESS DELETE_FAILED UPDATE_ROLLBACK_FAILED	Most likely usable
Warning	UPDATE_ROLLBACK_IN_PROGRESS UPDATE_ROLLBACK_COMPLETE_CLEANUP_IN_PROGRESS UPDATE_ROLLBACK_COMPLETE	Recovering after some problem
Healthy	CREATE_COMPLETE UPDATE_IN_PROGRESS UPDATE_COMPLETE_CLEANUP_IN_PROGRESS UPDATE_COMPLETE	Usable

The full health model for an AWS CloudFormation stack is as follows:

Customize the AWS Management Pack

To change the frequency of discoveries, rules, and monitors, you can override the interval time (in seconds).

To change frequency

1. In the **Operations Manager** toolbar, click **Go**, and then click **Authoring**.
2. In the **Authoring** pane, expand **Management Pack Objects** and then click the object to change (for example, **Object Discoveries**, **Rules**, or **Monitors**).
3. In the toolbar, click **Scope**.
4. In the **Scope Management Pack Objects** dialog box, click **View all targets**.
5. To limit the scope to Amazon objects, type Amazon in the **Look for** field.
6. Select the object want to configure and click **OK**.
7. In the **Operations Manager** center pane, right-click the object to configure, click **Overrides**, and then click the type of override you want to configure.
8. Use the **Override Properties** dialog box to configure different values and settings for objects.

Tip

To disable a discovery, rule, or monitoring object right-click the object to disable in the **Operations Manager** center pane, click **Overrides**, and then click **Disable the Rule**. You might disable rules if, for example, you do not run AWS Elastic Beanstalk applications or use custom Amazon CloudWatch metrics.

For information about creating overrides, see [Tuning Monitoring by Using Targeting and Overrides](#) on the *Microsoft TechNet* website.

For information about creating custom rules and monitors, see [Authoring for System Center 2012 - Operations Manager](#) or [System Center Operations Manager 2007 R2 Management Pack Authoring Guide](#) on the *Microsoft TechNet* website.

Upgrade the AWS Management Pack

The procedure that you'll use to update AWS Management Pack depends on the version of System Center.

System Center 2012

To upgrade the AWS Management Pack

1. On the [AWS Add-Ins for Microsoft System Center](#) website, click **SCOM 2012**. Download AWS-SCOM-MP-2.0-2.5.zip to your computer and unzip it. The .zip file includes Amazon.AmazonWebServices.mpb.
2. In the Operations console, on the **Go** menu, click **Administration**, and then click **Management Packs**.
3. In the **Tasks** pane, click **Import Management Packs**.
4. On the **Select Management Packs** page, click **Add**, and then click **Add from disk**.
5. In the **Select Management Packs to import** dialog box, select the Amazon.AmazonWebServices.mpb file from the location where you downloaded it, and then click **Open**.
6. On the **Select Management Packs** page, under **Import list**, select the **Amazon Web Services** management pack, and then click **Install**.

If the **Install** button is disabled, upgrading to the current version is not supported and you must uninstall the AWS Management Pack before you can install the current version. For more information, see [Uninstall the AWS Management Pack \(p. 2236\)](#).

System Center 2007 R2

To upgrade the AWS Management Pack

1. On the Management Server, go to the [AWS Add-Ins for Microsoft System Center](#) website and click **SCOM 2007**. Save AWS-MP-Setup-2.5.msi, and then run it.
2. Click **Next** and follow the directions to upgrade the components that you installed previously.
3. If your root management server, Operations console, and watcher node are on different computers, you must download and run the setup program on each computer.
4. On the watcher node, open a Command Prompt window as an administrator and run the following commands.

```
C:\> net stop HealthService
The System Center Management service is stopping.
The System Center Management service was stopped successfully.

C:\> net start HealthService
The System Center Management service is starting.
The System Center Management service was started successfully.
```

5. In the Operations console, on the **Go** menu, click **Administration**, and then click **Management Packs**.
6. In the **Actions** pane, click **Import Management Packs**.
7. On the **Select Management Packs** page, click **Add**, and then click **Add from disk**.
8. In the **Select Management Packs to import** dialog box, change the directory to C:\Program Files (x86)\Amazon Web Services Management Pack, select the Amazon.AmazonWebServices.mp file, and then click **Open**.
9. On the **Select Management Packs** page, under **Import list**, select the **Amazon Web Services** management pack, and then click **Install**.

If the **Install** button is disabled, upgrading to the current version is not supported and you must uninstall AWS Management Pack first. For more information, see [Uninstall the AWS Management Pack \(p. 2236\)](#).

Uninstall the AWS Management Pack

If you need to uninstall the AWS Management Pack, use the following procedure.

System Center 2012

To uninstall the AWS Management Pack

1. In the Operations console, on the **Go** menu, click **Administration**, and then click **Management Packs**.
2. Right-click **Amazon Web Services** and select **Delete**.
3. In the **Dependent Management Packs** dialog box, note the dependent management packs, and then click **Close**.
4. Right-click the dependent management pack and select **Delete**.
5. Right-click **Amazon Web Services** and select **Delete**.

System Center 2007 R2

To uninstall the AWS Management Pack

1. Complete steps 1 through 5 described for System Center 2012 in the previous section.
2. From Control Panel, open Programs and Features. Select **Amazon Web Services Management Pack** and then click **Uninstall**.
3. If your root management server, Operations console, and watcher node are on different computers, you must repeat this process on each computer.

Troubleshoot the AWS Management Pack

The following are common errors, events, and troubleshooting steps.

Contents

- [Errors 4101 and 4105 \(p. 2236\)](#)
- [Error 4513 \(p. 2237\)](#)
- [Event 623 \(p. 2237\)](#)
- [Events 2023 and 2120 \(p. 2237\)](#)
- [Event 6024 \(p. 2238\)](#)
- [General troubleshooting for System Center 2012 — Operations Manager \(p. 2238\)](#)
- [General troubleshooting for System Center 2007 R2 \(p. 2238\)](#)

Errors 4101 and 4105

If you receive one of the following errors, you must upgrade the AWS Management Pack. For more information, see [Upgrade the AWS Management Pack \(p. 2234\)](#).

```
Error 4101
Exception calling "DescribeVolumes" with "1" argument(s): "AWS was not able to validate
the
provided access credentials"
```

```
Error 4105
Exception calling "DescribeApplications" with "0" argument(s): "The security token
included
in the request is invalid"
```

Error 4513

If you receive one of the following error, you must upgrade the AWS Management Pack. For more information, see [Upgrade the AWS Management Pack \(p. 2234\)](#).

```
Error 4513
The callback method DeliverDataToModule failed with exception "Resolution of the
dependency
failed, type = "Amazon.SCOM.SDK.Interfaces.IMonitorSdk", name = "(none)".
Exception occurred while: Calling constructor Amazon.SCOM.SDK.CloudWatch.AwsMonitorSdk
(System.String awsAccessKey, System.String awsSecretKey).
Exception is: InvalidOperationException - Collection was modified; enumeration operation
may not run.
```

Event 623

If you find the following event in the Windows event log, follow the solution described in [KB975057](#).

```
Event ID: 623
HealthService (process_id) The version store for instance instance ("name") has reached
its maximum size of size MB. It is likely that a long-running transaction is preventing
cleanup of the version store and causing it to build up in size. Updates will be rejected
until the long-running transaction has been completely committed or rolled back.
Possible long-running transaction:
SessionId: id
Session-context: value
Session-context ThreadId: id
Cleanup: value
```

Events 2023 and 2120

If you find the following events in the Windows event log, see [Event ID 2023 and 2120](#) for more information.

```
Event ID: 2023
The Health Service has removed some items from the send queue for management group
"Servers"
since it exceeded the maximum allowed size of size megabytes.
```

```
Event ID: 2120
The Health Service has deleted one or more items for management group "Servers" which
could
not be sent in 1440 minutes.
```

Event 6024

If you find the following event in the Windows event log, see [SCOM 2012 - Event ID 6024](#) for more information.

Event ID: 6024

LaunchRestartHealthService.js : Launching Restart Health Service. Health Service exceeded Process\Handle Count or Private Bytes threshold.

General troubleshooting for System Center 2012 — Operations Manager

Try the following to resolve any issues.

- Verify that you have installed the latest Update Rollup for System Center 2012 — Operations Manager. The AWS Management Pack requires at least Update Rollup 1.
- Ensure that you have configured the AWS Management Pack after importing it by running the Add Monitoring Wizard. For more information, see [Step 1: Install the AWS Management Pack \(p. 2211\)](#).
- Verify that you have waited long enough for the AWS resources to be discovered (10–20 minutes).
- Verify that the management servers are configured properly.
 - Management servers must have Internet connectivity.
 - The action account for a management server must have local administrator privileges on the management server.
 - The management server must have the .NET Framework 4.5. or later.
- Verify that the AWS Run As account is valid.
 - The values for the access key ID and secret access key are correct.
 - The access keys are active: In the AWS Management Console, click your name in the navigation bar and then click **Security Credentials**.
- The IAM user has at least read-only access permission. Note that read-only access allows the user actions that do not change the state of a resource, such as monitoring, but do not allow the user actions like launching or stopping an instance.
 - If an Amazon CloudWatch metric shows as **Not Monitored**, check whether at least one Amazon CloudWatch alarm has been defined for that Amazon CloudWatch metric.
 - For further troubleshooting, use the information in the event logs.
- Check the Operations Manager event log on the management server. For more information, see [Events \(p. 2231\)](#) for a list of the events that the AWS Management Pack writes to the Operations Manager event log.

General troubleshooting for System Center 2007 R2

Try the following to resolve any issues.

- Ensure that you have configured the AWS Management Pack after importing it by running the Add Monitoring Wizard. For more information, see [Step 1: Install the AWS Management Pack \(p. 2211\)](#).
- Verify that you have waited long enough for the AWS resources to be discovered (10–20 minutes).
- Verify that the watcher node is configured properly.
 - The proxy agent is enabled. For more information, see [Step 2: Configure the watcher node \(p. 2212\)](#).
 - The watcher node has Internet connectivity.
 - The action account for the watcher node has local administrator privileges.

- The watcher node must have the .NET Framework 3.5.1 or later.
- Verify that the watcher node is healthy and resolve all alerts. For more information, see [Views \(p. 2220\)](#).
- Verify that the AWS Run As account is valid.
 - The values for the access key ID and secret access key are correct.
 - The access keys are active: In the AWS Management Console, click your name in the navigation bar and then click **Security Credentials**.
 - The IAM user has at least read-only access permission. Note that read-only access allows the user actions that do not change the state of a resource, such as monitoring, but do not allow the user actions like launching or stopping an instance.
 - If an Amazon CloudWatch metric shows as **Not Monitored**, check whether at least one Amazon CloudWatch alarm has been defined for that Amazon CloudWatch metric.
 - For further troubleshooting, use the information in the event logs.
 - Check the Operations Manager event log on the management server as well as the watcher node. For more information, see [Events \(p. 2231\)](#) for a list of the events that the AWS Management Pack writes to the Operations Manager event log.

The following general resources can help you as you work with AWS.

- [Classes & Workshops](#) – Links to role-based and specialty courses, in addition to self-paced labs to help sharpen your AWS skills and gain practical experience.
- [AWS Developer Center](#) – Explore tutorials, download tools, and learn about AWS developer events.
- [AWS Developer Tools](#) – Links to developer tools, SDKs, IDE toolkits, and command line tools for developing and managing AWS applications.

- [Getting Started Resource Center](#) – Learn how to set up your AWS account, join the AWS community, and launch your first application.
- [Hands-On Tutorials](#) – Follow step-by-step tutorials to launch your first application on AWS.
- [AWS Whitepapers](#) – Links to a comprehensive list of technical AWS whitepapers, covering topics such as architecture, security, and economics and authored by AWS Solutions Architects or other technical experts.
- [AWS Support Center](#) – The hub for creating and managing your AWS Support cases. Also includes links to other helpful resources, such as forums, technical FAQs, service health status, and AWS Trusted Advisor.
- [AWS Support](#) – The primary webpage for information about AWS Support, a one-on-one, fast-response support channel to help you build and run applications in the cloud.
- [Contact Us](#) – A central contact point for inquiries concerning AWS billing, account, events, abuse, and other issues.
- [AWS Site Terms](#) – Detailed information about our copyright and trademark; your account, license, and site access; and other topics.

Document history

The following table describes important additions to the Amazon EC2 documentation starting in 2019. We also update the documentation frequently to address the feedback that you send us.

Change	Description	Date
<u>Hibernation support for M7i and M7i-flex</u>	Hibernate your newly-launched instances running on M7i and M7i-flex instance types.	August 22, 2023
<u>Hpc7a instances (p. 2242)</u>	New compute optimized instance types that feature 4th generation AMD EPYC processors. These instance types support up to 300 Gbps networking bandwidth, and up to 192 CPU cores with up to 768 GB of system memory.	August 17, 2023
<u>M7a instances (p. 2242)</u>	New general purpose instances powered by 4th generation AMD EPYC processors.	August 15, 2023
<u>EC2-Classic has been deprecated (p. 2242)</u>	With EC2-Classic, EC2 instances ran in a single, flat network shared with other customers. Amazon VPC replaces EC2-Classic. With Amazon VPC, your instances run in a virtual private cloud (VPC) that's logically isolated to your AWS account.	August 8, 2023
<u>M7i-flex instances (p. 2242)</u>	New general purpose instances that offer a balance of compute, memory, and network resources for a broad spectrum of general purpose applications. They deliver a baseline CPU performance of 40 percent with the ability to deliver up to 100 percent CPU performance for 95 percent of the time over a 24-hour period.	August 2, 2023
<u>M7i instances (p. 2242)</u>	New general purpose instance types that feature 4th generation Intel Xeon Scalable processors.	August 2, 2023
<u>P5 instances (p. 2242)</u>	New accelerated computing instances that feature 8 NVIDIA H100 GPUs with 640 GB high-bandwidth GPU memory, 3rd generation AMD EPYC	July 26, 2023

	processors, and 2 TB system memory.	
<u>Amazon EBS performance updates</u>	Updated Amazon EBS performance for R6a instances.	June 29, 2023
<u>Hpc7g instances (p. 2242)</u>	New high-performance computing instances powered by AWS Graviton3E processors that provide up to 35 percent higher vector-instruction processing performance than Graviton3 processors.	June 20, 2023
<u>Dedicated Hosts</u>	You can allocate Dedicated Hosts on specific hardware assets on an Outpost.	June 20, 2023
<u>C7gn instances (p. 2242)</u>	New compute optimized instances powered by the latest generation AWS Graviton3E processors and the new AWS Nitro cards. These instances offer up to 200 Gbps network bandwidth.	June 20, 2023
<u>EC2 Instance Connect Endpoint</u>	You can now connect to an instance via SSH or RDP without requiring the instance to have a public IPv4 address.	June 13, 2023
<u>IMDS Package Analyzer</u>	You can now use the IMDS Packet Analyzer to identify sources of IMDSv1 calls on your EC2 instances.	June 1, 2023
<u>Launch template quotas</u>	You can now view your quotas for launch templates and launch template versions in the Service Quotas console and by using the Service Quotas CLI.	April 3, 2023
<u>Capacity Reservation utilization notifications</u>	AWS Health now sends notifications when capacity utilization for Capacity Reservations in your account drops below 20 percent.	April 3, 2023
<u>Amazon EBS performance updates</u>	Updated Amazon EBS performance for M6a and C6a instances.	April 3, 2023
<u>Capacity Reservation groups</u>	You can now add Capacity Reservations that are shared with you to Capacity Reservation groups that you own.	March 30, 2023
<u>New bare metal instances (p. 2242)</u>	Bare metal instances for C6in, M6idn, M6in, R6idn, and R6in.	March 21, 2023

<u>Modify instance metadata options</u>	You can now use the Amazon EC2 console to modify instance metadata options.	March 20, 2023
<u>UEFI preferred</u>	You can now create a single AMI that supports both Unified Extensible Firmware Interface (UEFI) and Legacy BIOS boot modes.	March 3, 2023
<u>Modify an AMI for IMDSv2</u>	Modify your existing AMI so that instances launched from the AMI require IMDSv2 by default.	February 28, 2023
<u>Add supported instances for ENA Express</u>	Added a table with new and existing supported instance types for ENA Express.	February 13, 2023
<u>Windows Virtualization-based security - Credential Guard</u>	You can enable Credential Guard, a Virtualization-based security (VBS) feature, on supported Amazon EC2 instances.	January 31, 2023
<u>Fault testing on Amazon EBS</u>	Use AWS FIS to temporarily stop I/O between an EBS volume and the instances to which it is attached to test how your workloads handle I/O interruptions.	January 27, 2023
<u>AMI alias in launch templates</u>	You can specify an AWS Systems Manager parameter instead of the AMI ID in your launch templates to avoid having to update the templates every time the AMI ID changes.	January 19, 2023
<u>Hibernation support for C6i, I3en, and M6i</u>	Hibernate your newly-launched instances running on C6i, I3en, and M6i instance types.	December 19, 2022
<u>Torn write prevention</u>	Improve the performance of your I/O-intensive relational database workloads and reduce latency without negatively impacting data resiliency with torn write prevention, a block storage feature.	November 29, 2022
<u>Hpc6id instance (p. 2242)</u>	New memory optimized instance featuring 3rd generation Intel Xeon Scalable processors (Ice Lake).	November 29, 2022
<u>R6in and R6idn instances (p. 2242)</u>	New memory optimized instances for network-intensive workloads.	November 28, 2022

<u>M6in and M6idn instances (p. 2242)</u>	New general computing instances types.	November 28, 2022
<u>ENA Express</u>	Increase throughput and minimize tail latency of network traffic between EC2 instances with ENA Express.	November 28, 2022
<u>C6in instances (p. 2242)</u>	New compute optimized instances ideal for running high performance computing.	November 28, 2022
<u>Recycle Bin retention rule lock</u>	You can lock retention rules to help protect them against accidental or malicious modifications and deletions.	November 23, 2022
<u>Copy AMI tags</u>	When you copy an AMI, you can copy your user-defined AMI tags at the same time.	November 18, 2022
<u>AMI size for store and restore</u>	The size of an AMI (before compression) that can be stored and restored to and from an Amazon S3 bucket can now be up to 5,000 GB.	November 16, 2022
<u>priceCapacityOptimized allocation strategy for Spot Instances</u>	A Spot Fleet that uses the priceCapacityOptimized allocation strategy looks at both price and capacity to select the Spot Instances pools that are the least likely to be interrupted and have the lowest possible price.	November 10, 2022
<u>price-capacity-optimized allocation strategy for Spot Instances</u>	An EC2 Fleet that uses the price-capacity-optimized allocation strategy looks at both price and capacity to select the Spot Instances pools that are the least likely to be interrupted and have the lowest possible price.	November 10, 2022
<u>Cancel having an AMI shared with your account</u>	If an AMI has been shared with your AWS account and you no longer want it shared with your account, you can remove your account from the AMI's launch permissions.	November 4, 2022
<u>Transfer Elastic IP addresses</u>	You can now transfer Elastic IP addresses from one AWS account to another.	October 31, 2022
<u>Replace root volume</u>	You can replace the root Amazon EBS volume for a running instance using an AMI.	October 27, 2022

<u>Trn1 instances (p. 2242)</u>	New accelerated computing instances optimized for deep learning powered by AWS Trainium chips.	October 10, 2022
<u>Automatically connect instance to database</u>	Use the automatic connection feature to quickly connect one or more EC2 instances to an RDS database to allow traffic between them.	October 10, 2022
<u>AMI quotas</u>	Quotas now apply to creating and sharing AMIs.	October 10, 2022
<u>Configure AMI for IMDSv2</u>	Configure your AMI so that instances launched from the AMI require IMDSv2 by default.	October 3, 2022
<u>Initiate Spot Instance interruption</u>	You can select a Spot Instance in the Amazon EC2 console and initiate an interruption so that you can test how the applications on your Spot Instances handle being interrupted.	September 26, 2022
<u>Verified AMI provider</u>	In the Amazon EC2 console, public AMIs that are owned by Amazon or a verified Amazon partner are marked Verified provider .	July 22, 2022
<u>R6a instances (p. 2242)</u>	New memory optimized instances featuring 3rd generation AMD EPYC processors.	July 19, 2022
<u>Placement groups on AWS Outposts</u>	Added a host spread strategy for placement groups on an Outpost.	June 30, 2022
<u>Condition keys for Recycle Bin</u>	You can use the <code>rbin:Request/ResourceType</code> and <code>rbin:Attribute/ResourceType</code> condition keys to filter access on Recycle Bin requests.	June 14, 2022
<u>R6id instances (p. 2242)</u>	New memory optimized instances featuring 3rd generation Intel Xeon Scalable processors (Ice Lake).	June 9, 2022
<u>io2 Block Express volumes</u>	You can modify the size and provisioned IOPS of io2 Block Express volumes and you can enable them for fast snapshot restore.	May 31, 2022

<u>Dedicated Hosts on AWS Outposts</u>	You can allocate Dedicated Hosts on AWS Outposts.	May 31, 2022
<u>M6id instances (p. 2242)</u>	New general purpose instances featuring 3rd generation Intel Xeon Scalable processors (Ice Lake).	May 26, 2022
<u>C6id instances (p. 2242)</u>	New compute optimized instances featuring 3rd generation Intel Xeon Scalable processors (Ice Lake).	May 26, 2022
<u>Instance stop protection</u>	To prevent your instance from being accidentally stopped, you can enable stop protection for the instance.	May 24, 2022
<u>C7g instances (p. 2242)</u>	New compute optimized instances featuring the latest AWS Graviton3 processors.	May 23, 2022
<u>UEFI Secure Boot</u>	UEFI Secure Boot builds on the long-standing secure boot process of Amazon EC2 and provides additional defense-in-depth that helps customers secure software from threats that persist across reboots.	May 10, 2022
<u>NitroTPM</u>	Nitro Trusted Platform Module (NitroTPM) is a virtual device that is provided by the AWS Nitro System and conforms to the TPM 2.0 specification.	May 10, 2022
<u>AMI state change events</u>	Amazon EC2 now generates an event when an AMI changes state. You can use Amazon EventBridge to detect and react to these events.	May 9, 2022
<u>Describe public keys</u>	You can query the public key and creation date of an Amazon EC2 key pair.	April 28, 2022
<u>Create key pairs</u>	You can specify the key format (PEM or PPK) when creating a new key pair.	April 28, 2022
<u>I4i instances (p. 2242)</u>	New storage optimized instances featuring 3rd generation Intel Xeon Scalable processors (Ice Lake).	April 27, 2022

<u>Mount Amazon FSx file systems at launch</u>	You can mount a new or existing Amazon FSx for NetApp ONTAP or Amazon FSx for OpenZFS file system at launch using the new launch instance wizard.	April 12, 2022
<u>New launch instance wizard</u>	A new and improved launch experience in the Amazon EC2 console, providing a quicker and easier way to launch an EC2 instance.	April 5, 2022
<u>Automatically deprecate public AMIs</u>	By default, the deprecation date of all public AMIs is set to two years from the AMI creation date.	March 31, 2022
<u>Instance metadata category: autoscaling/target-lifecycle-state</u>	When using Auto Scaling groups, you can access an instance's target lifecycle state from the instance metadata.	March 24, 2022
<u>X2idn and X2iedn instances (p. 2242)</u>	New memory optimized instances featuring Intel Xeon Scalable processors (Ice Lake).	March 10, 2022
<u>AMI last launched time</u>	The <code>lastLaunchedTime</code> indicates when your AMI was last used to launch an instance.	February 28, 2022
<u>C6a instances (p. 2242)</u>	New compute optimized instances featuring 3rd generation AMD EPYC processors (Milan).	February 14, 2022
<u>Recycle Bin for AMIs</u>	Recycle Bin enables you to restore accidentally deleted AMIs.	February 3, 2022
<u>X2iezn instances (p. 2242)</u>	New memory optimized instances featuring Intel Xeon Platinum processors (Cascade Lake).	January 26, 2022
<u>New Local Zones added</u>	Add Local Zones in Atlanta, Phoenix, and Seattle.	January 11, 2022
<u>Configure Windows AMIs for faster launching</u>	Configure Windows AMIs to launch instances up to 65% faster, using pre-provisioned snapshots.	January 10, 2022
<u>Instance tags in instance metadata</u>	You can access an instance's tags from the instance metadata.	January 6, 2022
<u>Capacity Reservations in cluster placement groups</u>	You can create Capacity Reservations in cluster placement groups.	January 6, 2022

<u>Recycle Bin for Amazon EBS snapshots</u>	Recycle Bin for Amazon EBS snapshots is a snapshot recovery feature that enables you to restore accidentally deleted snapshots.	November 29, 2021
<u>M6a instances (p. 2242)</u>	New general purpose instances powered by AMD 3rd Generation EPYC processors.	November 29, 2021
<u>Amazon EBS Snapshots Archive</u>	Amazon EBS Snapshots Archive is a new storage tier that you can use for low-cost, long-term storage of your rarely-accessed snapshots.	November 29, 2021
<u>R6i instances (p. 2242)</u>	New memory optimized instances.	November 22, 2021
<u>G5 instances (p. 2242)</u>	New accelerated computing instances featuring up to 8 NVIDIA A10G GPUs and second generation AMD EPY processors.	November 11, 2021
<u>Spot Fleet launch-before-terminate</u>	Spot Fleet can terminate the Spot Instances that receive a rebalance notification after new replacement Spot Instances are launched.	November 4, 2021
<u>EC2 Fleet launch-before-terminate</u>	EC2 Fleet can terminate the Spot Instances that receive a rebalance notification after new replacement Spot Instances are launched.	November 4, 2021
<u>Share AMIs with organizations and OUs</u>	You can now share AMIs with the following AWS resources: organizations and organizational units (OUs).	October 29, 2021
<u>C6i instances (p. 2242)</u>	New compute optimized instances featuring Intel Xeon Scalable processors (Ice Lake).	October 28, 2021
<u>Spot placement score</u>	Get a recommendation for an AWS Region or Availability Zone based on your Spot capacity requirements.	October 27, 2021
<u>Attribute-based instance type selection for Spot Fleet</u>	Specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes.	October 27, 2021
<u>Attribute-based instance type selection for EC2 Fleet</u>	Specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes.	October 27, 2021

<u>New Local Zones added</u>	Add Local Zones in Las Vegas, New York City, and Portland.	October 26, 2021
<u>On-Demand Capacity Reservation Fleet</u>	You can use a Capacity Reservation Fleet to launch a group, or fleet, of Capacity Reservations.	October 5, 2021
<u>Hibernation support for Ubuntu 20.04 LTS - Focal</u>	Hibernate your newly-launched instances that were launched from the Ubuntu 20.04 LTS - Focal AMI.	October 4, 2021
<u>EC2 Fleet and targeted On-Demand Capacity Reservations</u>	EC2 Fleet can launch On-Demand Instances into targeted Capacity Reservations.	September 22, 2021
<u>T3 instances on Dedicated Hosts</u>	Support for T3 instances on Amazon EC2 Dedicated Host.	September 14, 2021
<u>Hibernation support for RHEL, Fedora, and CentOS</u>	Hibernate your newly-launched instances that were launched from RHEL, Fedora, and CentOS AMIs.	September 9, 2021
<u>New Local Zones added</u>	Add Local Zones in Chicago, Minneapolis, and Kansas City.	September 8, 2021
<u>Amazon EC2 Global View</u>	Amazon EC2 Global View enables you to view VPCs, subnets, instances, security groups, and volumes across multiple AWS Regions in a single console.	September 1, 2021
<u>AMI deprecation support for Amazon Data Lifecycle Manager</u>	Amazon Data Lifecycle Manager EBS-backed AMI policies can deprecate AMIs. The <code>AWSDataLifecycleManagerServiceRoleForAMIManagement</code> AWS managed policy has been updated to support this feature.	August 23, 2021
<u>Hibernation support for C5d, M5d, and R5d</u>	Hibernate your newly-launched instances running on C5d, M5d, and R5d instance types.	August 19, 2021
<u>Amazon EC2 key pairs</u>	Amazon EC2 now supports ED25519 keys on Linux and Mac instances.	August 17, 2021
<u>M6i instances (p. 2242)</u>	New general purpose instances featuring third generation Intel Xeon Scalable processors (Ice Lake).	August 16, 2021
<u>CloudWatch metrics for Amazon Data Lifecycle Manager</u>	You can monitor your Amazon Data Lifecycle Manager policies using Amazon CloudWatch.	July 28, 2021

<u>New Local Zone added</u>	Add Local Zone in Denver.	July 27, 2021
<u>CloudTrail data events for EBS direct APIs</u>	The ListSnapshotBlocks, ListChangedBlocks, GetSnapshotBlock, and PutSnapshotBlock APIs can be logged data events in CloudTrail.	July 27, 2021
<u>Prefixes for network interfaces</u>	You can assign a private IPv4 or IPv6 CIDR range, either automatically or manually, to your network interfaces.	July 22, 2021
<u>io2 Block Express volumes</u>	io2 Block Express volumes are now generally available in all Regions and Availability Zones that support R5b instances.	July 19, 2021
<u>Event windows</u>	You can define custom, weekly-recurring event windows for scheduled events that reboot, stop, or terminate your Amazon EC2 instances.	July 15, 2021
<u>Resource IDs and tagging support for security group rules (p. 2242)</u>	You can refer to security group rules by resource ID. You can also add tags to your security group rules.	July 7, 2021
<u>New Local Zones added</u>	Add Local Zones in Dallas and Philadelphia.	July 7, 2021
<u>Deprecate an AMI</u>	You can now specify when an AMI is deprecated.	June 11, 2021
<u>Windows per-second billing (p. 2242)</u>	Amazon EC2 charges for Windows- and SQL Server-based usage by the second, with a one-minute minimum charge.	June 10, 2021
<u>Capacity Reservations on AWS Outposts</u>	You can now use Capacity Reservations on AWS Outposts.	May 24, 2021
<u>Capacity Reservation sharing</u>	You can now share Capacity Reservations created in Local Zones and Wavelength Zones.	May 24, 2021
<u>High memory virtualized instances (p. 2242)</u>	Virtualized high memory instances purpose-built to run large in-memory databases. The new types are u-6tb1.56xlarge, u-6tb1.112xlarge, u-9tb1.112xlarge, and u-12tb1.112xlarge.	May 11, 2021
<u>Root volume replacement</u>	You can now use root volume replacement tasks to replace the root EBS volume for running instances.	April 22, 2021

<u>Store and restore an AMI using S3</u>	Store EBS-backed AMIs in S3 and restore them from S3 to enable cross-partition copying of AMIs.	April 6, 2021
<u>EC2 Serial Console</u>	Troubleshoot boot and network connectivity issues by establishing a connection to the serial port of an instance.	March 30, 2021
<u>Boot modes</u>	Amazon EC2 now supports UEFI boot on selected AMD- and Intel-based EC2 instances.	March 22, 2021
<u>Amazon EBS local snapshots on Outposts</u>	You can now use Amazon EBS local snapshots on Outposts to store snapshots of volumes on an Outpost locally in Amazon S3 on the Outpost itself.	February 4, 2021
<u>Create a reverse DNS record</u>	You can now set up reverse DNS lookup for your Elastic IP addresses.	February 3, 2021
<u>Amazon Data Lifecycle Manager</u>	Use Amazon Data Lifecycle Manager to automate the process of sharing snapshots and copying them across AWS accounts.	December 17, 2020
<u>G4ad instances (p. 2242)</u>	New instances powered by AMD Radeon Pro V520 GPUs and AMD 2nd Generation EPYC processors.	December 9, 2020
<u>Tag AMIs and snapshots on AMI creation</u>	When you create an AMI, you can tag the AMI and the snapshots with the same tags, or you can tag them with different tags.	December 4, 2020
<u>io2 Block Express preview</u>	You can opt in to the io2 Block Express volumes preview. io2 Block Express volumes provide sub-millisecond latency, and support higher IOPS, higher throughput, and larger capacity than io2 volumes.	December 1, 2020
<u>gp3 volumes (p. 2242)</u>	A new Amazon EBS General Purpose SSD volume type. You can specify provisioned IOPS and throughput when you create or modify the volume.	December 1, 2020
<u>D3, D3en, M5zn, and R5b instances (p. 2242)</u>	New instance types built on the Nitro System.	December 1, 2020

<u>Throughput Optimized HDD and Cold HDD volume sizes</u>	Throughput Optimized HDD (st1) and Cold HDD (sc1) volumes can range in size from 125 GiB to 16 TiB.	November 30, 2020
<u>Use Amazon EventBridge to monitor Spot Fleet events</u>	Create EventBridge rules that trigger programmatic actions in response to Spot Fleet state changes and errors.	November 20, 2020
<u>Use Amazon EventBridge to monitor EC2 Fleet events</u>	Create EventBridge rules that trigger programmatic actions in response to EC2 Fleet state changes and errors.	November 20, 2020
<u>Delete instant fleets</u>	Delete an EC2 Fleet of type instant and terminate all the instances in the fleet in a single API call.	November 18, 2020
<u>Hibernation support for T3 and T3a</u>	Hibernate your newly-launched instances running on T3 and T3a instance types.	November 17, 2020
<u>Amazon Data Lifecycle Manager</u>	You can use Amazon Data Lifecycle Manager to automate the creation, retention, and deletion of EBS-backed AMIs.	November 9, 2020
<u>Instance metadata category: events/recommendations/rebalance</u>	The approximate time, in UTC, when the EC2 instance rebalance recommendation notification is emitted for the instance.	November 4, 2020
<u>EC2 instance rebalance recommendation</u>	A signal that notifies you when a Spot Instance is at elevated risk of interruption.	November 4, 2020
<u>Capacity Reservations in Wavelength Zones</u>	Capacity Reservations can now be created and used in Wavelength Zones.	November 4, 2020
<u>Capacity Rebalancing</u>	Configure Spot Fleet or EC2 Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation.	November 4, 2020
<u>Hibernation support for I3, M5ad, and R5ad</u>	Hibernate your newly-launched instances running on I3, M5ad, and R5ad instance types.	October 21, 2020
<u>Spot Instance vCPU limits</u>	Spot Instance limits are now managed in terms of the number of vCPUs that your running Spot Instances are either using or will use pending the fulfillment of open requests.	October 1, 2020

<u>Capacity Reservations in Local Zones</u>	Capacity Reservations can now be created and used in Local Zones.	September 30, 2020
<u>Amazon Data Lifecycle Manager</u>	Amazon Data Lifecycle Manager policies can be configured with up to four schedules.	September 17, 2020
<u>Hibernation support for M5a and R5a</u>	Hibernate your newly-launched instances running on M5a and R5a instance types.	August 28, 2020
<u>Provisioned IOPS SSD (io2) volumes for Amazon EBS</u>	Provisioned IOPS SSD (io2) volumes are designed to provide 99.999 percent volume durability with an AFR no higher than 0.001 percent.	August 24, 2020
<u>Instance metadata provides instance location and placement information</u>	New instance metadata fields under the placement category: Region, placement group name, partition number, host ID, and Availability Zone ID.	August 24, 2020
<u>C5ad instances (p. 2242)</u>	New compute optimized instances featuring second-generation AMD EPYC processors.	August 13, 2020
<u>Wavelength Zones</u>	A Wavelength Zone is an isolated zone in the carrier location where the Wavelength infrastructure is deployed.	August 6, 2020
<u>Capacity Reservation groups</u>	You can use AWS Resource Groups to create logical collections of Capacity Reservations, and then target instance launches into those groups.	July 29, 2020
<u>Fast snapshot restore</u>	You can enable fast snapshot restore for snapshots that are shared with you.	July 21, 2020
<u>EC2Launch v2 (p. 692)</u>	You can use EC2Launch v2 to perform tasks during instance startup, if an instance is stopped and later started, if an instance is restarted, and on demand. EC2Launch v2 supports all versions of Windows Server and replaces EC2Launch and EC2Config.	June 30, 2020
<u>Bare metal instances for G4dn (p. 2242)</u>	New instances that provide your applications with direct access to the physical resources of the host server.	June 5, 2020

C5a instances (p. 2242)	New compute optimized instances featuring second-generation AMD EPYC processors.	June 4, 2020
Bring your own IPv6 addresses	You can bring part or all of your IPv6 address range from your on-premises network to your AWS account.	May 21, 2020
Launch instances using a Systems Manager parameter	You can specify a AWS Systems Manager parameter instead of an AMI when you launch an instance.	May 5, 2020
Customize scheduled event notifications	You can customize scheduled event notifications to include tags in the email notification.	May 4, 2020
Windows Server on Dedicated Hosts	You can use Windows Server AMIs provided by Amazon to run the latest versions of Windows Server on Dedicated Hosts.	April 7, 2020
Stop and start a Spot Instance	Stop your Spot Instances backed by Amazon EBS and start them at will, instead of relying on the stop interruption behavior.	January 13, 2020
Resource tagging (p. 2242)	You can tag egress-only internet gateways, local gateways, local gateway route tables, local gateway virtual interfaces, local gateway virtual interface groups, local gateway route table VPC associations, and local gateway route table virtual interface group associations.	January 10, 2020
Connect to your instance using Session Manager	You can start a Session Manager session with an instance from the Amazon EC2 console.	December 18, 2019
Dedicated Hosts and host resource groups	Dedicated Hosts can now be used with host resource groups.	December 2, 2019
Dedicated Host sharing	You can now share your Dedicated Hosts across AWS accounts.	December 2, 2019
Default credit specification at the account level	You can set the default credit specification per burstable performance instance family at the account level per AWS Region.	November 25, 2019
Instance type discovery	You can find an instance type that meets your needs.	November 22, 2019

<u>Dedicated Hosts (p. 2242)</u>	You can now configure a Dedicated Host to support multiple instance types in an instance family.	November 21, 2019
<u>Amazon EBS fast snapshot restores</u>	You can enable fast snapshot restores on an EBS snapshot to ensure that EBS volumes created from the snapshot are fully-initialized at creation and instantly deliver all of their provisioned performance.	November 20, 2019
<u>Instance Metadata Service Version 2</u>	You can use Instance Metadata Service Version 2, which is a session-oriented method for requesting instance metadata.	November 19, 2019
<u>Hibernation support for On-Demand Windows instances</u>	You can hibernate On-Demand Windows instances.	October 14, 2019
<u>Queued purchases of Reserved Instances</u>	You can queue the purchase of a Reserved Instance up to three years in advance.	October 4, 2019
<u>G4dn instances (p. 2242)</u>	New instances featuring NVIDIA Tesla GPUs.	September 19, 2019
<u>Diagnostic interrupt</u>	You can send a diagnostic interrupt to an unreachable or unresponsive instance to trigger a blue screen/stop error.	August 14, 2019
<u>Capacity optimized allocation strategy</u>	Using EC2 Fleet or Spot Fleet, you can launch Spot Instances from Spot pools with optimal capacity for the number of instances that are launching.	August 12, 2019
<u>On-Demand Capacity Reservation sharing</u>	You can now share your Capacity Reservations across AWS accounts.	July 29, 2019
<u>Resource tagging (p. 2242)</u>	Launch templates on creation.	July 24, 2019
<u>Host recovery</u>	Automatically restart your instances on a new host in the event of an unexpected hardware failure on a Dedicated Host.	June 5, 2019
<u>Amazon EBS multi-volume snapshots</u>	You can take exact point-in-time, data coordinated, and crash-consistent snapshots across multiple EBS volumes attached to an EC2 instance.	May 29, 2019
<u>Resource tagging (p. 2242)</u>	You can tag Dedicated Host Reservations.	May 27, 2019

<u>Amazon EBS encryption by default</u>	After you enable encryption by default in a Region, all new EBS volumes you create in the Region are encrypted using the default KMS key for EBS encryption.	May 23, 2019
<u>VSS application-consistent snapshots</u>	Take application-consistent snapshots of all Amazon EBS volumes attached to your Windows instances using AWS Systems Manager Run Command.	May 13, 2019
<u>Resource tagging (p. 2242)</u>	You can tag VPC endpoints, endpoint services, and endpoint service configurations.	May 13, 2019
<u>Windows to Linux Replatforming Assistant for Microsoft SQL Server Databases</u>	Move existing Microsoft SQL Server workloads from a Windows to a Linux operating system.	May 8, 2019
<u>I3en instances (p. 2242)</u>	New I3en instances can utilize up to 100 Gbps of network bandwidth.	May 8, 2019
<u>Windows Automated Upgrade</u>	Perform automated upgrades of EC2 Windows instances using AWS Systems Manager.	May 6, 2019
<u>T3a instances (p. 2242)</u>	New instances featuring AMD EPYC processors.	April 24, 2019
<u>M5ad and R5ad instances (p. 2242)</u>	New instances featuring AMD EPYC processors.	March 27, 2019
<u>Resource tagging (p. 2242)</u>	You can assign custom tags to your Dedicated Host Reservations to categorize them in different ways.	March 14, 2019
<u>Bare metal instances for M5, M5d, R5, R5d, and z1d (p. 2242)</u>	New instances that provide your applications with direct access to the physical resources of the host server.	February 13, 2019

History for previous years

The following table describes important additions to the Amazon EC2 documentation in 2018 and earlier years.

Feature	API version	Description	Release date
Partition placement groups	2016-11-15	Partition placement groups spread instances across logical partitions, ensuring that instances in one partition do not share underlying hardware with instances in other partitions. For more information, see Partition placement groups (p. 1353) .	20 December 2018
p3dn.24xlarge instances	2016-11-15	New p3dn.24xlarge instances provide 100 Gbps of network bandwidth.	7 December 2018
Instances featuring 100 Gbps of network bandwidth	2016-11-15	New C5n instances can utilize up to 100 Gbps of network bandwidth.	26 November 2018
Spot console recommends a fleet of instances	2016-11-15	The Spot console recommends a fleet of instances based on Spot best practice (instance diversification) to meet the minimum hardware specifications (vCPUs, memory, and storage) for your application need. For more information, see Create a Spot Fleet request (p. 1058) .	20 November 2018
New EC2 Fleet request type: instant	2016-11-15	EC2 Fleet now supports a new request type, instant, that you can use to synchronously provision capacity across instance types and purchase models. The instant request returns the launched instances in the API response, and takes no further action, enabling you to control if and when instances are launched. For more information, see EC2 Fleet request types (p. 964) .	14 November 2018
Instances featuring AMD EPYC processors	2016-11-15	New general purpose (M5a) and memory optimized instances (R5a) offer lower-priced options for microservices, small to medium databases, virtual desktops, development and test environments, business applications, and more.	6 November 2018
Spot savings information	2016-11-15	You can view the savings made from using Spot Instances for a single Spot Fleet or for all Spot Instances. For more information, see Savings from purchasing Spot Instances (p. 402) .	5 November 2018
Console support for optimizing CPU options	2016-11-15	When you launch an instance, you can optimize the CPU options to suit specific workloads or business needs using the Amazon EC2 console. For more information, see Optimize CPU options (p. 803) .	31 October 2018
Console support for creating a launch template from an instance	2016-11-15	You can create a launch template using an instance as the basis for a new launch template using the Amazon EC2 console. For more information, see Create a launch template (p. 570) .	30 October 2018

Feature	API version	Description	Release date
On-Demand Capacity Reservations	2016-11-15	You can reserve capacity for your Amazon EC2 instances in a specific Availability Zone for any duration. This allows you to create and manage capacity reservations independently from the billing discounts offered by Reserved Instances (RI). For more information, see On-Demand Capacity Reservations (p. 504) .	25 October 2018
Bring Your Own IP Addresses (BYOIP)	2016-11-15	You can bring part or all of your public IPv4 address range from your on-premises network to your AWS account. After you bring the address range to AWS, it appears in your account as an address pool. You can create an Elastic IP address from your address pool and use it with your AWS resources. For more information, see Bring your own IP addresses (BYOIP) in Amazon EC2 (p. 1254) .	23 October 2018
g3s.xlarge instances	2016-11-15	Expands the range of the accelerated-computing G3 instance family with the introduction of g3s.xlarge instances.	11 October 2018
Dedicated Host tag on create and console support	2016-11-15	You can tag your Dedicated Hosts on creation, and you can manage your Dedicated Host tags using the Amazon EC2 console. For more information, see Allocate Dedicated Hosts (p. 464) .	08 October 2018
High memory instances	2016-11-15	These instances are purpose-built to run large in-memory databases. They offer bare metal performance with direct access to host hardware. For more information, see Memory optimized instances (p. 291) .	27 September 2018
f1.4xlarge instances	2016-11-15	Expands the range of the accelerated-computing F1 instance family with the introduction of f1.4xlarge instances.	25 September 2018
Console support for scheduled scaling for Spot Fleet	2016-11-15	Increase or decrease the current capacity of the fleet based on the date and time. For more information, see Scale Spot Fleet using scheduled scaling (p. 1078) .	20 September 2018
T3 instances	2016-11-15	T3 instances are burstable general-purpose instance type that provide a baseline level of CPU performance with the ability to burst CPU usage at any time for as long as required. For more information, see Burstable performance instances (p. 245) .	21 August 2018
Allocation strategies for EC2 Fleets	2016-11-15	You can specify whether On-Demand capacity is fulfilled by price (lowest price first) or priority (highest priority first). You can specify the number of Spot pools across which to allocate your target Spot capacity. For more information, see Allocation strategies for Spot Instances (p. 983) .	26 July 2018

Feature	API version	Description	Release date
Allocation strategies for Spot Fleets	2016-11-15	You can specify whether On-Demand capacity is fulfilled by price (lowest price first) or priority (highest priority first). You can specify the number of Spot pools across which to allocate your target Spot capacity. For more information, see Allocation strategies for Spot Instances (p. 1027) .	26 July 2018
R5 and R5d instances	2016-11-15	R5 and R5d instances are ideally suited for high-performance databases, distributed in-memory caches, and in-memory analytics. R5d instances come with NVMe instance store volumes. For more information, see Memory optimized instances (p. 291) .	25 July 2018
z1d instances	2016-11-15	These instances are designed for applications that require high per-core performance with a large amount of memory, such as electronic design automation (EDA) and relational databases. These instances come with NVME instance store volumes. For more information, see Memory optimized instances (p. 291) .	25 July 2018
Automate snapshot lifecycle	2016-11-15	You can use Amazon Data Lifecycle Manager to automate creation and deletion of snapshots for your EBS volumes. For more information, see Amazon Data Lifecycle Manager (p. 1859) .	12 July 2018
Launch template CPU options	2016-11-15	When you create a launch template using the command line tools, you can optimize the CPU options to suit specific workloads or business needs. For more information, see Create a launch template (p. 570) .	11 July 2018
Tag Dedicated Hosts	2016-11-15	You can tag your Dedicated Hosts. For more information, see Tag Dedicated Hosts (p. 475) .	3 July 2018
i3.metal instances	2016-11-15	i3.metal instances provide your applications with direct access to the physical resources of the host server, such as processors and memory. For more information, see Storage optimized instances (p. 313) .	17 May 2018
Get latest console output	2016-11-15	You can retrieve the latest console output for some instance types when you use the get-console-output AWS CLI command.	9 May 2018
Optimize CPU options	2016-11-15	When you launch an instance, you can optimize the CPU options to suit specific workloads or business needs. For more information, see Optimize CPU options (p. 803) .	8 May 2018

Feature	API version	Description	Release date
EC2 Fleet	2016-11-15	You can use EC2 Fleet to launch a group of instances across different EC2 instance types and Availability Zones, and across On-Demand Instance, Reserved Instance, and Spot Instance purchasing models. For more information, see EC2 Fleet (p. 962) .	2 May 2018
On-Demand Instances in Spot Fleets	2016-11-15	You can include a request for On-Demand capacity in your Spot Fleet request to ensure that you always have instance capacity. For more information, see Spot Fleet (p. 1025) .	2 May 2018
Tag EBS snapshots on creation	2016-11-15	You can apply tags to snapshots during creation. For more information, see Create Amazon EBS snapshots (p. 1762) .	2 April 2018
Change placement groups	2016-11-15	You can move an instance in or out of a placement group, or change its placement group. For more information, see Change the placement group for an instance (p. 1363) .	1 March 2018
Longer resource IDs	2016-11-15	You can enable the longer ID format for more resource types. For more information, see Resource IDs (p. 2076) .	9 February 2018
Network performance improvements	2016-11-15	Instances outside of a cluster placement group can now benefit from increased bandwidth when sending or receiving network traffic between other instances or Amazon S3.	24 January 2018
Tag Elastic IP addresses	2016-11-15	You can tag your Elastic IP addresses. For more information, see Tag an Elastic IP address (p. 1271) .	21 December 2017
Amazon Time Sync Service	2016-11-15	You can use the Amazon Time Sync Service to keep accurate time on your instance. For more information, see Set the time for a Windows instance (p. 839) .	29 November 2017
T2 Unlimited	2016-11-15	T2 Unlimited instances can burst above the baseline for as long as required. For more information, see Burstable performance instances (p. 245) .	29 November 2017
Launch templates	2016-11-15	A launch template can contain all or some of the parameters to launch an instance, so that you don't have to specify them every time you launch an instance. For more information, see Launch an instance from a launch template (p. 567) .	29 November 2017
Spread placement	2016-11-15	Spread placement groups are recommended for applications that have a small number of critical instances that should be kept separate from each other. For more information, see Spread placement groups (p. 1354) .	29 November 2017

Feature	API version	Description	Release date
H1 instances	2016-11-15	H1 instances are designed for high-performance big data workloads. For more information, see Storage optimized instances (p. 313) .	28 November 2017
M5 instances	2016-11-15	M5 instances are general purpose compute instances. They provide a balance of compute, memory, storage, and network resources.	28 November 2017
Spot Instance hibernation	2016-11-15	The Spot service can hibernate Spot Instances in the event of an interruption. For more information, see Hibernate interrupted Spot Instances (p. 435) .	28 November 2017
Spot Fleet target tracking	2016-11-15	You can set up target tracking scaling policies for your Spot Fleet. For more information, see Scale Spot Fleet using a target tracking policy (p. 1075) .	17 November 2017
Spot Fleet integrates with Elastic Load Balancing	2016-11-15	You can attach one or more load balancers to a Spot Fleet.	10 November 2017
X1e instances	2016-11-15	X1e instances are ideally suited for high-performance databases, in-memory databases, and other memory-intensive enterprise applications. For more information, see Memory optimized instances (p. 291) .	28 November 2017
C5 instances	2016-11-15	C5 instances are designed for compute-heavy applications. For more information, see Compute optimized instances (p. 279) .	6 November 2017
Merge and split Convertible Reserved Instances	2016-11-15	You can exchange (merge) two or more Convertible Reserved Instances for a new Convertible Reserved Instance. You can also use the modification process to split a Convertible Reserved Instance into smaller reservations. For more information, see Exchange Convertible Reserved Instances (p. 387) .	6 November 2017
P3 instances	2016-11-15	P3 instances are compute-optimized GPU instances. For more information, see Windows accelerated computing instances (p. 321) .	25 October 2017
Modify VPC tenancy	2016-11-15	You can change the instance tenancy attribute of a VPC from dedicated to default. For more information, see Change the tenancy of a VPC (p. 504) .	16 October 2017
Stop on interruption	2016-11-15	You can specify whether Amazon EC2 should stop or terminate Spot Instances when they are interrupted. For more information, see Interruption behavior (p. 434) .	18 September 2017
Tag NAT gateways	2016-11-15	You can tag your NAT gateway. For more information, see Tag your resources (p. 2086) .	7 September 2017

Feature	API version	Description	Release date
Security group rule descriptions	2016-11-15	You can add descriptions to your security group rules. For more information, see Security group rules (p. 1676) .	31 August 2017
Elastic Graphics	2016-11-15	Attach Elastic Graphics accelerators to your instances to accelerate the graphics performance of your applications. For more information, see Amazon Elastic Graphics (p. 1135) .	29 August 2017
Recover Elastic IP addresses	2016-11-15	If you release an Elastic IP address for use in a VPC, you might be able to recover it. For more information, see Recover an Elastic IP address (p. 1278) .	11 August 2017
Tag Spot Fleet instances	2016-11-15	You can configure your Spot Fleet to automatically tag the instances that it launches.	24 July 2017
G3 instances	2016-11-15	G3 instances provide a cost-effective, high-performance platform for graphics applications using DirectX or OpenGL. G3 instances also provide NVIDIA GRID Virtual Workstation features, supporting 4 monitors with resolutions up to 4096x2160. For more information, see Windows accelerated computing instances (p. 321) .	13 July 2017
Tag resources during creation	2016-11-15	You can apply tags to instances and volumes during creation. For more information, see Tag your resources (p. 2086) . In addition, you can use tag-based resource-level permissions to control the tags that are applied. For more information see, Grant permission to tag resources during creation (p. 1599) .	28 March 2017
I3 instances	2016-11-15	I3 instances are storage optimized instances. For more information, see Storage optimized instances (p. 313) .	23 February 2017
Perform modifications on attached EBS volumes	2016-11-15	With most EBS volumes attached to most EC2 instances, you can modify volume size, type, and IOPS without detaching the volume or stopping the instance. For more information, see Amazon EBS Elastic Volumes (p. 1909) .	13 February 2017
Attach an IAM role	2016-11-15	You can attach, detach, or replace an IAM role for an existing instance. For more information, see IAM roles for Amazon EC2 (p. 1649) .	9 February 2017
Dedicated Spot Instances	2016-11-15	You can run Spot Instances on single-tenant hardware in a virtual private cloud (VPC). For more information, see Specify a tenancy for your Spot Instances (p. 406) .	19 January 2017
IPv6 support	2016-11-15	You can associate an IPv6 CIDR with your VPC and subnets, and assign IPv6 addresses to instances in your VPC. For more information, see Amazon EC2 instance IP addressing (p. 1235) .	1 December 2016

Feature	API version	Description	Release date
R4 instances	2016-09-15	R4 instances are memory optimized instances. R4 instances are well-suited for memory-intensive, latency-sensitive workloads such as business intelligence (BI), data mining and analysis, in-memory databases, distributed web scale in-memory caching, and applications performance real-time processing of unstructured big data. For more information, see Memory optimized instances (p. 291)	30 November 2016
New t2.xlarge and t2.2xlarge instance types	2016-09-15	T2 instances are designed to provide moderate base performance and the capability to burst to significantly higher performance as required by your workload. They are intended for applications that need responsiveness, high performance for limited periods of time, and a low cost. For more information, see Burstable performance instances (p. 245) .	30 November 2016
P2 instances	2016-09-15	P2 instances use NVIDIA Tesla K80 GPUs and are designed for general purpose GPU computing using the CUDA or OpenCL programming models. For more information, see Windows accelerated computing instances (p. 321) .	29 September 2016
m4.16xlarge instances	2016-04-01	Expands the range of the general-purpose M4 family with the introduction of m4.16xlarge instances, with 64 vCPUs and 256 GiB of RAM.	6 September 2016
Automatic scaling for Spot Fleet		You can now set up scaling policies for your Spot Fleet. For more information, see Automatic scaling for Spot Fleet (p. 1073) .	1 September 2016
Elastic Network Adapter (ENA)	2016-04-01	You can now use ENA for enhanced networking. For more information, see Enhanced networking support (p. 1326) .	28 June 2016
Enhanced support for viewing and modifying longer IDs	2016-04-01	You can now view and modify longer ID settings for other IAM users, IAM roles, or the root user. For more information, see Resource IDs (p. 2076) .	23 June 2016
Copy encrypted Amazon EBS snapshots between AWS accounts	2016-04-01	You can now copy encrypted EBS snapshots between AWS accounts. For more information, see Copy an Amazon EBS snapshot (p. 1781) .	21 June 2016
Capture a screenshot of an instance console	2015-10-01	You can now obtain additional information when debugging instances that are unreachable. For more information, see Troubleshoot an unreachable instance (p. 2126) .	24 May 2016

Feature	API version	Description	Release date
X1 instances	2015-10-01	Memory-optimized instances designed for running in-memory databases, big data processing engines, and high performance computing (HPC) applications. For more information, see Memory optimized instances (p. 291) .	18 May 2016
Two new EBS volume types	2015-10-01	You can now create Throughput Optimized HDD (st1) and Cold HDD (sc1) volumes. For more information, see Amazon EBS volume types (p. 1707) .	19 April 2016
Added new NetworkPacketsIn and NetworkPacketsOut metrics for Amazon EC2		Added new NetworkPacketsIn and NetworkPacketsOut metrics for Amazon EC2. For more information, see Instance metrics (p. 1185) .	23 March 2016
CloudWatch metrics for Spot Fleet		You can now get CloudWatch metrics for your Spot Fleet. For more information, see CloudWatch metrics for Spot Fleet (p. 1071) .	21 March 2016
Scheduled Instances	2015-10-01	Scheduled Reserved Instances (Scheduled Instances) enable you to purchase capacity reservations that recur on a daily, weekly, or monthly basis, with a specified start time and duration.	13 January 2016
Longer resource IDs	2015-10-01	We're gradually introducing longer length IDs for some Amazon EC2 and Amazon EBS resource types. During the opt-in period, you can enable the longer ID format for supported resource types. For more information, see Resource IDs (p. 2076) .	13 January 2016
ClassicLink DNS support	2015-10-01	You can enable ClassicLink DNS support for your VPC so that DNS hostnames that are addressed between linked EC2-Classic instances and instances in the VPC resolve to private IP addresses and not public IP addresses.	11 January 2016
New t2.nano instance type	2015-10-01	T2 instances are designed to provide moderate base performance and the capability to burst to significantly higher performance as required by your workload. They are intended for applications that need responsiveness, high performance for limited periods of time, and a low cost. For more information, see Burstable performance instances (p. 245) .	15 December 2015
Dedicated hosts	2015-10-01	An Amazon EC2 Dedicated host is a physical server with instance capacity dedicated for your use. For more information, see Dedicated Hosts (p. 458) .	23 November 2015

Feature	API version	Description	Release date
Spot Instance duration	2015-10-01	You can now specify a duration for your Spot Instances. Spot blocks is not supported (January 2023).	6 October 2015
Spot Fleet modify request	2015-10-01	You can now modify the target capacity of your Spot Fleet request. For more information, see Modify a Spot Fleet request (p. 1069) .	29 September 2015
Spot Fleet diversified allocation strategy	2015-04-15	You can now allocate Spot Instances in multiple Spot pools using a single Spot Fleet request. For more information, see Allocation strategies for Spot Instances (p. 1027) .	15 September 2015
Spot Fleet instance weighting	2015-04-15	You can now define the capacity units that each instance type contributes to your application's performance, and adjust the amount you are willing to pay for Spot Instances for each Spot pool accordingly. For more information, see Spot Fleet instance weighting (p. 1048) .	31 August 2015
New reboot alarm action and new IAM role for use with alarm actions		Added the reboot alarm action and new IAM role for use with alarm actions. For more information, see Create alarms that stop, terminate, reboot, or recover an instance (p. 1207) .	23 July 2015
New t2.large instance type		T2 instances are designed to provide moderate base performance and the capability to burst to significantly higher performance as required by your workload. They are intended for applications that need responsiveness, high performance for limited periods of time, and a low cost. For more information, see Burstable performance instances (p. 245) .	16 June 2015
M4 instances		General-purpose instances that provide a balance of compute, memory, and network resources. M4 instances are powered by a custom Intel 2.4 GHz Intel® Xeon® E5 2676v3 (Haswell) processor with AVX2.	11 June 2015
Spot Fleets	2015-04-15	You can manage a collection, or fleet, of Spot Instances instead of managing separate Spot Instance requests. For more information, see Spot Fleet (p. 1025) .	18 May 2015
Migrate Elastic IP addresses to EC2-Classic	2015-04-15	You can migrate an Elastic IP address that you've allocated for use in EC2-Classic to be used in a VPC..	15 May 2015
Importing VMs with multiple disks as AMIs	2015-03-01	The VM Import process now supports importing VMs with multiple disks as AMIs. For more information, see Importing a VM as an Image Using VM Import/Export in the <i>VM Import/Export User Guide</i> .	23 April 2015

Feature	API version	Description	Release date
New g2.8xlarge instance type		The new g2.8xlarge instance is backed by four high-performance NVIDIA GPUs, making it well suited for GPU compute workloads including large scale rendering, transcoding, machine learning, and other server-side workloads that require massive parallel processing power.	7 April 2015
D2 instances		<p>Dense-storage instances that are optimized for applications requiring sequential access to large amount of data on direct attached instance storage. D2 instances are designed to offer best price/performance in the dense-storage family. Powered by 2.4 GHz Intel® Xeon® E5 2676v3 (Haswell) processors, D2 instances improve on HS1 instances by providing additional compute power, more memory, and Enhanced Networking. In addition, D2 instances are available in four instance sizes with 6TB, 12TB, 24TB, and 48TB storage options.</p> <p>For more information, see Storage optimized instances (p. 313).</p>	24 March 2015
Systems Manager		Systems Manager enables you to configure and manage your EC2 instances.	17 February 2015
Systems Manager for Microsoft SCVMM 1.5		You can now use Systems Manager for Microsoft SCVMM to launch an instance and to import a VM from SCVMM to Amazon EC2. For more information, see Create an EC2 Instance (p. 2196) and Import your virtual machine (p. 2201) .	21 January 2015
Automatic recovery for EC2 instances		<p>You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. A recovered instance is identical to the original instance, including the instance ID, IP addresses, and all instance metadata.</p> <p>For more information, see Recover your instance (p. 622).</p>	12 January 2015

Feature	API version	Description	Release date
C4 instances		<p>Next-generation compute-optimized instances that provide very high CPU performance at an economical price. C4 instances are based on custom 2.9 GHz Intel® Xeon® E5-2666 v3 (Haswell) processors. With additional Turbo boost, the processor clock speed in C4 instances can reach as high as 3.5Ghz with 1 or 2 core turbo. Expanding on the capabilities of C3 compute-optimized instances, C4 instances offer customers the highest processor performance among EC2 instances. These instances are ideally suited for high-traffic web applications, ad serving, batch processing, video encoding, distributed analytics, high-energy physics, genome analysis, and computational fluid dynamics.</p> <p>For more information, see Compute optimized instances (p. 279).</p>	11 January 2015
ClassicLink	2014-10-01	ClassicLink enables you to link your EC2-Classic instance to a VPC in your account. You can associate VPC security groups with the EC2-Classic instance, enabling communication between your EC2-Classic instance and instances in your VPC using private IP addresses.	7 January 2015
Spot Instance termination notices		<p>The best way to protect against Spot Instance interruption is to architect your application to be fault tolerant. In addition, you can take advantage of Spot Instance termination notices, which provide a two-minute warning before Amazon EC2 must terminate your Spot Instance.</p> <p>For more information, see Spot Instance interruption notices (p. 440).</p>	5 January 2015
Systems Manager for Microsoft SCVMM		Systems Manager for Microsoft SCVMM provides a simple, easy-to-use interface for managing AWS resources, such as EC2 instances, from Microsoft SCVMM. For more information, see AWS Systems Manager for Microsoft System Center VMM (p. 2191) .	29 October 2014
DescribeVolumes pagination support	2014-09-01	The DescribeVolumes API call now supports the pagination of results with the MaxResults and NextToken parameters. For more information, see DescribeVolumes in the <i>Amazon EC2 API Reference</i> .	23 October 2014

Feature	API version	Description	Release date
Added support for Amazon CloudWatch Logs		You can use Amazon CloudWatch Logs to monitor, store, and access your system, application, and custom log files from your instances or other sources. You can then retrieve the associated log data from CloudWatch Logs using the Amazon CloudWatch console, the CloudWatch Logs commands in the AWS CLI, or the CloudWatch Logs SDK.	10 July 2014
T2 instances	2014-06-15	T2 instances are designed to provide moderate base performance and the capability to burst to significantly higher performance as required by your workload. They are intended for applications that need responsiveness, high performance for limited periods of time, and a low cost. For more information, see Burstable performance instances (p. 245) .	30 June 2014
New EC2 Service Limits page		Use the EC2 Service Limits page in the Amazon EC2 console to view the current limits for resources provided by Amazon EC2 and Amazon VPC, on a per-region basis.	19 June 2014
Amazon EBS General Purpose SSD Volumes	2014-05-01	General Purpose SSD volumes offer cost-effective storage that is ideal for a broad range of workloads. These volumes deliver single-digit millisecond latencies, the ability to burst to 3,000 IOPS for extended periods of time, and a base performance of 3 IOPS/GiB. General Purpose SSD volumes can range in size from 1 GiB to 1 TiB. For more information, see General Purpose SSD (gp2) volumes (p. 1711) .	16 June 2014
Windows Server 2012 R2		AMIs for Windows Server 2012 R2 use the new AWS PV drivers. For more information, see AWS PV drivers (p. 781) .	3 June 2014
AWS Management Pack		AWS Management Pack now supports for System Center Operations Manager 2012 R2. For more information, see AWS Management Pack for Microsoft System Center (p. 2206) .	22 May 2014
Amazon EBS encryption	2014-05-01	Amazon EBS encryption offers seamless encryption of EBS data volumes and snapshots, eliminating the need to build and maintain a secure key management infrastructure. EBS encryption enables data at rest security by encrypting your data using AWS managed keys. The encryption occurs on the servers that host EC2 instances, providing encryption of data as it moves between EC2 instances and EBS storage. For more information, see Amazon EBS encryption (p. 1921) .	21 May 2014

Feature	API version	Description	Release date
R3 instances	2014-02-01	<p>Memory-optimized instances with the best price point per GiB of RAM and high performance. These instances are ideally suited for relational and NoSQL databases, in-memory analytics solutions, scientific computing, and other memory-intensive applications that can benefit from the high memory per vCPU, high compute performance, and enhanced networking capabilities of R3 instances.</p> <p>For more information, see Amazon EC2 Instance Types.</p>	9 April 2014
Amazon EC2 Usage Reports		Amazon EC2 Usage Reports is a set of reports that shows cost and usage data of your usage of EC2. For more information, see Amazon EC2 usage reports (p. 2102) .	28 January 2014
Additional M3 instances	2013-10-15	The M3 instance sizes m3.medium and m3.large are now supported. For more information, see Amazon EC2 Instance Types .	20 January 2014
I2 instances	2013-10-15	These instances provide very high IOPS. I2 instances also support enhanced networking that delivers improved inter-instance latencies, lower network jitter, and significantly higher packet per second (PPS) performance. For more information, see Storage optimized instances (p. 313) .	19 December 2013
Updated M3 instances	2013-10-15	The M3 instance sizes, m3.xlarge and m3.2xlarge now support instance store with SSD volumes.	19 December 2013
Resource-level permissions for RunInstances	2013-10-15	You can now create policies in AWS Identity and Access Management to control resource-level permissions for the Amazon EC2 RunInstances API action. For more information and example policies, see Identity and access management for Amazon EC2 (p. 1589) .	20 November 2013
C3 instances	2013-10-15	<p>Compute-optimized instances that provide very high CPU performance at an economical price. C3 instances also support enhanced networking that delivers improved inter-instance latencies, lower network jitter, and significantly higher packet per second (PPS) performance. These instances are ideally suited for high-traffic web applications, ad serving, batch processing, video encoding, distributed analytics, high-energy physics, genome analysis, and computational fluid dynamics.</p> <p>For more information, see Amazon EC2 Instance Types.</p>	14 November 2013

Feature	API version	Description	Release date
Launching an instance from the AWS Marketplace		You can now launch an instance from the AWS Marketplace using the Amazon EC2 launch wizard. For more information, see Launch an AWS Marketplace instance (p. 592) .	11 November 2013
G2 instances	2013-10-01	These instances are ideally suited for video creation services, 3D visualizations, streaming graphics-intensive applications, and other server-side workloads requiring massive parallel processing power. For more information, see Windows accelerated computing instances (p. 321) .	4 November 2013
New launch wizard		There is a new and redesigned EC2 launch wizard. For more information, see Launch an instance using the old launch instance wizard (p. 561) .	10 October 2013
Modifying Amazon EC2 Reserved Instances	2013-08-15	You can now modify Reserved Instances in a Region.	11 September 2013
Assigning a public IP address	2013-07-15	You can now assign a public IP address when you launch an instance in a VPC. For more information, see Assign a public IPv4 address during instance launch (p. 1239) .	20 August 2013
Granting resource-level permissions	2013-06-15	Amazon EC2 supports new Amazon Resource Names (ARNs) and condition keys. For more information, see IAM policies for Amazon EC2 (p. 1591) .	8 July 2013
Incremental Snapshot Copies	2013-02-01	You can now perform incremental snapshot copies. For more information, see Copy an Amazon EBS snapshot (p. 1781) .	11 June 2013
AWS Management Pack		The AWS Management Pack links Amazon EC2 instances and the Windows or Linux operating systems running inside them. The AWS Management Pack is an extension to Microsoft System Center Operations Manager. For more information, see AWS Management Pack for Microsoft System Center (p. 2206) .	8 May 2013
New Tags page		There is a new Tags page in the Amazon EC2 console. For more information, see Tag your Amazon EC2 resources (p. 2085) .	04 April 2013
Additional EBS-optimized instance types	2013-02-01	The following instance types can now be launched as EBS-optimized instances: c1.xlarge, m2.2xlarge, m3.xlarge, and m3.2xlarge. For more information, see Amazon EBS-optimized instances (p. 1941) .	19 March 2013

Feature	API version	Description	Release date
PV Drivers		To learn how to upgrade the paravirtualized (PV) drivers on your Windows AMI, see Upgrade PV drivers on Windows instances (p. 786) .	March 2013
Copy an AMI from one Region to another	2013-02-01	You can copy an AMI from one Region to another, enabling you to launch consistent instances in more than one AWS Region quickly and easily. For more information, see Copy an AMI (p. 166) .	11 March 2013
Launch instances into a default VPC	2013-02-01	Your AWS account is capable of launching instances into either EC2-Classic or a VPC, or only into a VPC, on a region-by-region basis. If you can launch instances only into a VPC, we create a default VPC for you. When you launch an instance, we launch it into your default VPC, unless you create a nondefault VPC and specify it when you launch the instance.	11 March 2013
High-memory cluster (cr1.8xlarge) instance type	2012-12-01	Have large amounts of memory coupled with high CPU and network performance. These instances are well suited for in-memory analytics, graph analysis, and scientific computing applications.	21 January 2013
High storage (hs1.8xlarge) instance type	2012-12-01	High storage instances provide very high storage density and high sequential read and write performance per instance. They are well-suited for data warehousing, Hadoop/MapReduce, and parallel file systems.	20 December 2012
EBS snapshot copy	2012-12-01	You can use snapshot copies to create backups of data, to create new Amazon EBS volumes, or to create Amazon Machine Images (AMIs). For more information, see Copy an Amazon EBS snapshot (p. 1781) .	17 December 2012
Updated EBS metrics and status checks for Provisioned IOPS SSD volumes	2012-10-01	Updated the EBS metrics to include two new metrics for Provisioned IOPS SSD volumes. For more information, see Amazon CloudWatch metrics for Amazon EBS (p. 1979) . Also added new status checks for Provisioned IOPS SSD volumes. For more information, see EBS volume status checks (p. 1747) .	20 November 2012

Feature	API version	Description	Release date
Support for Windows Server 2012		<p>Amazon EC2 now provides you with several pre-configured Windows Server 2012 AMIs. These AMIs are immediately available for use in every region and for every 64-bit instance type. The AMIs support the following languages:</p> <ul style="list-style-type: none"> • English • Chinese Simplified • Chinese Traditional • Chinese Traditional Hong Kong • Japanese • Korean • Portuguese • Portuguese Brazil • Czech • Dutch • French • German • Hungarian • Italian • Polish • Russian • Spanish • Swedish • Turkish 	19 November 2012
M3 instances	2012-10-01	There are new M3 extra-large and M3 double-extra-large instance types. For more information, see Amazon EC2 Instance Types .	31 October 2012
Spot Instance request status	2012-10-01	Spot Instance request status makes it easy to determine the state of your Spot requests.	14 October 2012
Amazon EC2 Reserved Instance Marketplace	2012-08-15	The Reserved Instance Marketplace matches sellers who have Amazon EC2 Reserved Instances that they no longer need with buyers who are looking to purchase additional capacity. Reserved Instances bought and sold through the Reserved Instance Marketplace work like any other Reserved Instances, except that they can have less than a full standard term remaining and can be sold at different prices.	11 September 2012
Provisioned IOPS SSD for Amazon EBS	2012-07-20	Provisioned IOPS SSD volumes deliver predictable, high performance for I/O intensive workloads, such as database applications, that rely on consistent and fast response times. For more information, see Amazon EBS volume types (p. 1707) .	31 July 2012

Feature	API version	Description	Release date
High I/O instances for Amazon EC2	2012-06-15	High I/O instances provides very high, low latency, disk I/O performance using SSD-based local instance storage.	18 July 2012
IAM roles on Amazon EC2 instances	2012-06-01	IAM roles for Amazon EC2 provide: <ul style="list-style-type: none"> • AWS access keys for applications running on Amazon EC2 instances. • Automatic rotation of the AWS access keys on the Amazon EC2 instance. • Granular permissions for applications running on Amazon EC2 instances that make requests to your AWS services. 	11 June 2012
Spot Instance features that make it easier to get started and handle the potential of interruption.		You can now manage your Spot Instances as follows: <ul style="list-style-type: none"> • Specify the amount you are willing to pay for Spot Instances using Auto Scaling launch configurations, and set up a schedule for specifying the amount you are willing to pay for Spot Instances. For more information, see Launching Spot Instances in Your Auto Scaling Group in the <i>Amazon EC2 Auto Scaling User Guide</i>. • Get notifications when instances are launched or terminated. • Use AWS CloudFormation templates to launch Spot Instances in a stack with AWS resources. 	7 June 2012
EC2 instance export and timestamps for status checks for Amazon EC2	2012-05-01	Added support for exporting Windows Server instances that you originally imported into EC2. Added support for timestamps on instance status and system status to indicate the date and time that a status check failed.	25 May 2012
EC2 instance export, and timestamps in instance and system status checks for Amazon VPC	2012-05-01	Added support for EC2 instance export to Citrix Xen, Microsoft Hyper-V, and VMware vSphere. Added support for timestamps in instance and system status checks.	25 May 2012
Cluster Compute Eight Extra Large instances	2012-04-01	Added support for cc2.8xlarge instances in a VPC.	26 April 2012
AWS Marketplace AMIs	2012-04-01	Added support for AWS Marketplace AMIs.	19 April 2012
Medium instances, support for 64-bit on all AMIs	2011-12-15	Added support for a new instance type and 64-bit information.	7 March 2012

Amazon Elastic Compute Cloud
User Guide for Windows Instances
History for previous years

Feature	API version	Description	Release date
Reserved Instance pricing tiers	2011-12-15	Added a new section discussing how to take advantage of the discount pricing that is built into the Reserved Instance pricing tiers.	5 March 2012
Elastic Network Interfaces (ENIs) for EC2 instances in Amazon Virtual Private Cloud	2011-12-01	Added new section about elastic network interfaces (ENIs) for EC2 instances in a VPC. For more information, see Elastic network interfaces (p. 1280) .	21 December 2011
New offering types for Amazon EC2 Reserved Instances	2011-11-01	You can choose from a variety of Reserved Instance offerings that address your projected use of the instance.	01 December 2011
Amazon EC2 instance status	2011-11-01	You can view additional details about the status of your instances, including scheduled events planned by AWS that might have an impact on your instances. These operational activities include instance reboots required to apply software updates or security patches, or instance retirements required where there are hardware issues. For more information, see Monitor the status of your instances (p. 1153) .	16 November 2011
Amazon EC2 Cluster Compute Instance Type		Added support for Cluster Compute Eight Extra Large (cc2.8xlarge) to Amazon EC2.	14 November 2011
Spot Instances in Amazon VPC	2011-07-15	Added information about the support for Spot Instances in Amazon VPC. With this update, users can launch Spot Instances a virtual private cloud (VPC). By launching Spot Instances in a VPC, users of Spot Instances can enjoy the benefits of Amazon VPC.	11 October 2011
Simplified VM import process for users of the CLI tools	2011-07-15	The VM Import process is simplified with the enhanced functionality of ImportInstance and ImportVolume, which now will perform the upload of the images into Amazon EC2 after creating the import task. In addition, with the introduction of ResumeImport, users can restart an incomplete upload at the point the task stopped.	15 September 2011
Support for importing in VHD file format		VM Import can now import virtual machine image files in VHD format. The VHD file format is compatible with the Citrix Xen and Microsoft Hyper-V virtualization platforms. With this release, VM Import now supports RAW, VHD and VMDK (VMware ESX-compatible) image formats. For more information, see the VM Import/Export User Guide .	24 August 2011

Amazon Elastic Compute Cloud
User Guide for Windows Instances
History for previous years

Feature	API version	Description	Release date
Support for Windows Server 2003 R2		VM Import now supports Windows Server 2003 (R2). With this release, VM Import supports all versions of Windows Server supported by Amazon EC2.	24 August 2011
Update to the Amazon EC2 VM Import Connector for VMware vCenter		Added information about the 1.1 version of the Amazon EC2 VM Import Connector for VMware vCenter virtual appliance (Connector). This update includes proxy support for Internet access, better error handling, improved task progress bar accuracy, and several bug fixes.	27 June 2011
Spot Instances Availability Zone pricing changes	2011-05-15	Added information about the Spot Instances Availability Zone pricing feature. In this release, we've added new Availability Zone pricing options as part of the information returned when you query for Spot Instance requests and Spot price history. These additions make it easier to determine the price required to launch a Spot Instance into a particular Availability Zone.	26 May 2011
AWS Identity and Access Management		Added information about AWS Identity and Access Management (IAM), which enables users to specify which Amazon EC2 actions a user can use with Amazon EC2 resources in general. For more information, see Identity and access management for Amazon EC2 (p. 1589) .	26 April 2011
Dedicated instances		Launched within your Amazon Virtual Private Cloud (Amazon VPC), Dedicated Instances are instances that are physically isolated at the host hardware level. Dedicated Instances let you take advantage of Amazon VPC and the AWS cloud, with benefits including on-demand elastic provisioning and pay only for what you use, while isolating your Amazon EC2 compute instances at the hardware level. For more information, see Dedicated Instances (p. 499) .	27 March 2011
Reserved Instances updates to the AWS Management Console		Updates to the AWS Management Console make it easier for users to view their Reserved Instances and purchase additional Reserved Instances, including Dedicated Reserved Instances.	27 March 2011
Support for Windows Server 2008 R2		Amazon EC2 now provides you with several pre-configured Windows Server 2008 R2 AMIs. These AMIs are immediately available for use in every region and in most 64-bit instance types, excluding t1.micro and HPC families. The AMIs will support multiple languages.	15 March 2011

Feature	API version	Description	Release date
Metadata information	2011-01-01	Added information about metadata to reflect changes in the 2011-01-01 release. For more information, see Instance metadata and user data (p. 862) and Instance metadata categories (p. 887) .	11 March 2011
Amazon EC2 VM Import Connector for VMware vCenter		Added information about the Amazon EC2 VM Import Connector for VMware vCenter virtual appliance (Connector). The Connector is a plug-in for VMware vCenter that integrates with VMware vSphere Client and provides a graphical user interface that you can use to import your VMware virtual machines to Amazon EC2.	3 March 2011
Force volume detachment		You can now use the AWS Management Console to force the detachment of an Amazon EBS volume from an instance. For more information, see Detach an Amazon EBS volume from a Windows instance (p. 1752) .	23 February 2011
Instance termination protection		You can now use the AWS Management Console to prevent an instance from being terminated. For more information, see Enable termination protection (p. 618) .	23 February 2011
VM Import	2010-11-15	Added information about VM Import, which allows you to import a virtual machine or volume into Amazon EC2. For more information, see the VM Import/Export User Guide .	15 December 2010
Basic monitoring for instances	2010-08-31	Added information about basic monitoring for EC2 instances.	12 December 2010
Filters and Tags	2010-08-31	Added information about listing, filtering, and tagging resources. For more information, see List and filter your resources (p. 2077) and Tag your Amazon EC2 resources (p. 2085) .	19 September 2010
Idempotent Instance Launch	2010-08-31	Added information about ensuring idempotency when running instances.	19 September 2010
Micro instances	2010-06-15	Amazon EC2 offers the t1.micro instance type for certain types of applications. For more information, see Burstable performance instances (p. 245) .	8 September 2010
AWS Identity and Access Management for Amazon EC2		Amazon EC2 now integrates with AWS Identity and Access Management (IAM). For more information, see Identity and access management for Amazon EC2 (p. 1589) .	2 September 2010

Amazon Elastic Compute Cloud
User Guide for Windows Instances
History for previous years

Feature	API version	Description	Release date
Cluster instances	2010-06-15	Amazon EC2 offers cluster compute instances for high-performance computing (HPC) applications. For more information, see Amazon EC2 Instance Types .	12 July 2010
Amazon VPC IP Address Designation	2010-06-15	Amazon VPC users can now specify the IP address to assign an instance launched in a VPC.	12 July 2010
Amazon CloudWatch monitoring for Amazon EBS Volumes		Amazon CloudWatch monitoring is now automatically available for Amazon EBS volumes. For more information, see Amazon CloudWatch metrics for Amazon EBS (p. 1979) .	14 June 2010
High-memory extra large instances	2009-11-30	Amazon EC2 now supports a High-Memory Extra Large (m2.xlarge) instance type. For more information, see Amazon EC2 Instance Types .	22 February 2010
Reserved Instances with Windows		Amazon EC2 now supports Reserved Instances with Windows.	22 February 2010
