What is Amazon EC2?

Amazon Elastic Compute Cloud (Amazon EC2) provides on-demand, scalable computing capacity in the Amazon Web Services (AWS) Cloud. Using Amazon EC2 reduces hardware costs so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage. You can add capacity (scale up) to handle compute-heavy tasks, such as monthly or yearly processes, or spikes in website traffic. When usage decreases, you can reduce capacity (scale down) again.

The following diagram shows a basic architecture of an Amazon EC2 instance deployed within an Amazon Virtual Private Cloud (VPC). In this example, the EC2 instance is within an Availability Zone in the Region. The EC2 instance is secured with a security group, which is a virtual firewall that controls incoming and outgoing traffic. A private key is stored on the local computer and a public key is stored on the instance. Both keys are specified as a key pair to prove the identity of the user. In this scenario, the instance is backed by an Amazon EBS volume. The VPC communicates with the internet using an internet gateway. For more information about Amazon VPC, see the [Amazon VPC User Guide](#).

Tip

This user guide provides information specific to running Windows-based instances on Amazon EC2. See the [EC2 User Guide for Linux Instances](#) for information to help you run Linux-based instances on EC2.

Amazon EC2 supports the processing, storage, and transmission of credit card data by a merchant or service provider, and has been validated as being compliant with Payment Card Industry (PCI) Data

Security Standard (DSS). For more information about PCI DSS, including how to request a copy of the AWS PCI Compliance Package, see [PCI DSS Level 1](#).

If you are looking for technical guidance about Amazon EC2, try [AWS re:Post](#).

For more information about cloud computing, see [What is cloud computing?](#)

Features of Amazon EC2

Amazon EC2 provides the following high-level features:

Instances

Virtual servers.

Amazon Machine Images (AMIs)

Preconfigured templates for your instances that package the components you need for your server (including the operating system and additional software).

Instance types

Various configurations of CPU, memory, storage, networking capacity, and graphics hardware for your instances.

Key pairs

Secure login information for your instances. AWS stores the public key and you store the private key in a secure place.

Instance store volumes

Storage volumes for temporary data that is deleted when you stop, hibernate, or terminate your instance.

Amazon EBS volumes

Persistent storage volumes for your data using Amazon Elastic Block Store (Amazon EBS).

Regions, Availability Zones, Local Zones, AWS Outposts, and Wavelength Zones

Multiple physical locations for your resources, such as instances and Amazon EBS volumes.

Security groups

A virtual firewall that allows you to specify the protocols, ports, and source IP ranges that can reach your instances, and the destination IP ranges to which your instances can connect.

Elastic IP addresses

Static IPv4 addresses for dynamic cloud computing.

Tags

Metadata that you can create and assign to your Amazon EC2 resources.

Virtual private clouds (VPCs)

Virtual networks you can create that are logically isolated from the rest of the AWS Cloud. You can optionally connect these virtual networks to your own network.

For details about all of the features of Amazon EC2, see [Amazon EC2 features](#). Windows-specific features and use case information can be found at [Windows Server on AWS](#).

For options to run your website on AWS, see [Web Hosting](#).

Get started with Amazon EC2

The following topics can help you get started with Amazon EC2. After you set up to use EC2, you can walk through [Tutorial: Get started with Amazon EC2 Windows instances \(p. 14\)](#) to launch, connect to, and clean up an instance. The remaining topics point to more information about the high-level features of EC2.

Set up and use an EC2 instance

- [Set up to use Amazon EC2 \(p. 7\)](#)
- [Tutorial: Get started with Amazon EC2 Windows instances \(p. 14\)](#)
- [Connect to your Windows instance](#)

- [Instance store \(p. 1996\)](#)

Work with Windows instances

- [AWS Systems Manager Run Command](#) in the [AWS Systems Manager User Guide](#)
- [Tutorial: Get started with Amazon EC2 Windows instances \(p. 14\)](#)

Troubleshoot EC2

- [Troubleshoot EC2 Windows instances](#)

- [AWS re:Post](#)

Related services

You can provision Amazon EC2 resources, such as instances and volumes, directly using Amazon EC2. In addition, you can provision EC2 resources using other AWS services, such as the following:

- [Amazon EC2 Auto Scaling](#)

Helps ensure you have the correct number of Amazon EC2 instances available to handle the load for your application.

- [AWS CloudFormation](#)

Helps you model and set up your AWS resources using templates.

- [AWS Elastic Beanstalk](#)

Deploy and manage applications in the AWS Cloud without having to understand the underlying infrastructure.

- [AWS OpsWorks](#)

Automate how servers are configured, deployed, and managed across your Amazon EC2 instances using Chef and Puppet.

- [EC2 Image Builder](#)

Automate the creation, management, and deployment of customized, secure, and up-to-date server images.

- [AWS Launch Wizard](#)

Size, configure, and deploy AWS resources for third-party applications without having to manually identify and provision individual AWS resources.

Additional related services

- [Amazon Lightsail](#)

To build websites or web applications, you can deploy and manage basic cloud resources using Amazon Lightsail. To compare the features of Amazon EC2 and Lightsail for your use case, see [Amazon Lightsail or Amazon EC2](#).

- [Elastic Load Balancing](#)

Automatically distribute incoming application traffic across multiple instances.

- [Amazon Relational Database Service \(Amazon RDS\)](#)

Set up, operate, and scale a managed relational database in the cloud. Although you can set up a database on an EC2 instance, Amazon RDS offers the advantage of handling your database management tasks, such as patching the software, backing up, and storing the backups.

- [Amazon Elastic Container Service \(Amazon ECS\)](#)

Deploy, manage, and scale containerized applications on a cluster of EC2 instances.

- [Amazon CloudWatch](#)

Monitor your instances and Amazon EBS volumes.

- [Amazon GuardDuty](#)

Detect potentially unauthorized or malicious use of your EC2 instances.

- [AWS Backup](#)

Automate backing up your Amazon EC2 instances and the Amazon EBS volumes attached to them.

Access Amazon EC2

You can create and manage your Amazon EC2 instances using the following interfaces:

Amazon EC2 console

A simple web interface to create and manage Amazon EC2 instances and resources. If you've signed up for an AWS account, you can access the Amazon EC2 console by signing into the AWS Management Console and selecting **EC2** from the console home page.

AWS Command Line Interface

Enables you to interact with AWS services using commands in your command-line shell. It is supported on Windows, Mac, and Linux. For more information about the AWS CLI , see [AWS Command Line Interface User Guide](#). You can find the Amazon EC2 commands in the [AWS CLI Command Reference](#).

AWS Tools for PowerShell

A set of PowerShell modules that are built on the functionality exposed by the AWS SDK for .NET. The Tools for PowerShell enable you to script operations on your AWS resources from the PowerShell command line. To get started, see the [AWS Tools for Windows PowerShell User Guide](#). You can find the cmdlets for Amazon EC2, in the [AWS Tools for PowerShell Cmdlet Reference](#).

AWS CloudFormation

Amazon EC2 supports creating resources using AWS CloudFormation. You create a template, in JSON or YAML format, that describes your AWS resources, and AWS CloudFormation provisions and configures those resources for you. You can reuse your CloudFormation templates to provision the same resources multiple times, whether in the same Region and account or in multiple Regions and accounts. For more information about supported resource types and properties for Amazon EC2, see [EC2 resource type reference](#) in the [AWS CloudFormation User Guide](#).

Query API

Amazon EC2 provides a Query API. These requests are HTTP or HTTPS requests that use the HTTP verbs GET or POST and a Query parameter named Action. For more information about the API actions for Amazon EC2, see [Actions](#) in the [Amazon EC2 API Reference](#).

AWS SDKs

If you prefer to build applications using language-specific APIs instead of submitting a request over HTTP or HTTPS, AWS provides libraries, sample code, tutorials, and other resources for software developers. These libraries provide basic functions that automate tasks such as cryptographically signing your requests, retrying requests, and handling error responses, making it easier for you to get started. For more information, see [Tools to Build on AWS](#).

Pricing for Amazon EC2

Amazon EC2 provides the following pricing options:

Free Tier

You can get started with Amazon EC2 for free. To explore the Free Tier options, see [AWS Free Tier](#).

On-Demand Instances

Pay for the instances that you use by the second, with a minimum of 60 seconds, with no long-term commitments or upfront payments.

Savings Plans

You can reduce your Amazon EC2 costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years.

Reserved Instances

You can reduce your Amazon EC2 costs by making a commitment to a specific instance configuration, including instance type and Region, for a term of 1 or 3 years.

Spot Instances

Request unused EC2 instances, which can reduce your Amazon EC2 costs significantly.

Dedicated Hosts

Reduce costs by using a physical EC2 server that is fully dedicated for your use, either On-Demand or as part of a Savings Plan. You can use your existing server-bound software licenses and get help meeting compliance requirements.

On-Demand Capacity Reservations

Reserve compute capacity for your EC2 instances in a specific Availability Zone for any duration of time.

Per-second billing

Removes the cost of unused minutes and seconds from your bill.

For a complete list of charges and prices for Amazon EC2 and more information about the purchase models, see [Amazon EC2 pricing](#).

Estimates, billing, and cost optimization

To create estimates for your AWS use cases, use the [AWS Pricing Calculator](#).

To estimate the cost of transforming **Microsoft workloads** to a modern architecture that uses open source and cloud-native services deployed on AWS, use the [AWS Modernization Calculator for Microsoft Workloads](#).

To see your bill, go to the **Billing and Cost Management Dashboard** in the [AWS Billing and Cost Management console](#). Your bill contains links to usage reports that provide details about your bill. To learn more about AWS account billing, see [AWS Billing and Cost Management User Guide](#).

If you have questions concerning AWS billing, accounts, and events, [contact AWS Support](#).

To calculate the cost of a sample provisioned environment, see [Cloud Economics Center](#). When calculating the cost of a provisioned environment, remember to include incidental costs such as snapshot storage for EBS volumes.

You can optimize the cost, security, and performance of your AWS environment using [AWS Trusted Advisor](#).

Set up to use Amazon EC2

Complete the tasks in this section to get set up for launching an Amazon EC2 instance for the first time:

1. [Sign up for an AWS account \(p. 7\)](#)
2. [Create an administrative user \(p. 7\)](#)
3. [Create a key pair \(p. 8\)](#)
4. [Create a security group \(p. 9\)](#)

When you are finished, you will be ready for the [Amazon EC2 Getting started \(p. 14\)](#) tutorial.

Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

1. Open <https://portal.aws.amazon.com/billing/signup>.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, [assign administrative access to an administrative user](#), and use only the root user to perform [tasks that require root user access](#).

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to <https://aws.amazon.com/> and choosing **My Account**.

Create an administrative user

After you sign up for an AWS account, create an administrative user so that you don't use the root user for everyday tasks.

Secure your AWS account root user

1. Sign in to the [AWS Management Console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

For help signing in by using root user, see [Signing in as the root user](#) in the *AWS Sign-In User Guide*.

2. Turn on multi-factor authentication (MFA) for your root user.

For instructions, see [Enable a virtual MFA device for your AWS account root user \(console\)](#) in the *IAM User Guide*.

Create an administrative user

- For your daily administrative tasks, grant administrative access to an administrative user in AWS IAM Identity Center (successor to AWS Single Sign-On).

For instructions, see [Getting started](#) in the *AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide*.

Sign in as the administrative user

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

For help signing in using an IAM Identity Center user, see [Signing in to the AWS access portal](#) in the *AWS Sign-In User Guide*.

Create a key pair

AWS uses public-key cryptography to secure the login information for your instance. You specify the name of the key pair when you launch your instance, then provide the private key to obtain the administrator password for your Windows instance so you can log in using Remote Desktop Protocol (RDP).

If you haven't created a key pair already, you can create one by using the Amazon EC2 console. Note that if you plan to launch instances in multiple AWS Regions, you'll need to create a key pair in each Region. For more information about Regions, see [Regions and Zones \(p. 1221\)](#).

To create your key pair

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Key Pairs**.
3. Choose **Create key pair**.
4. For **Name**, enter a descriptive name for the key pair. Amazon EC2 associates the public key with the name that you specify as the key name. A key name can include up to 255 ASCII characters. It can't include leading or trailing spaces.
5. For **Key pair type**, choose either **RSA** or **ED25519**. Note that **ED25519** keys are not supported for Windows instances.
6. For **Private key file format**, choose the format in which to save the private key. To save the private key in a format that can be used with OpenSSH, choose **pem**. To save the private key in a format that can be used with PuTTY, choose **ppk**.
7. Choose **Create key pair**.
8. The private key file is automatically downloaded by your browser. The base file name is the name you specified as the name of your key pair, and the file name extension is determined by the file format you chose. Save the private key file in a safe place.

Important

This is the only chance for you to save the private key file.

For more information, see [Amazon EC2 key pairs and Windows instances \(p. 1662\)](#).

Create a security group

Security groups act as a firewall for associated instances, controlling both inbound and outbound traffic at the instance level. You must add rules to a security group that enable you to connect to your instance from your IP address using RDP. You can also add rules that allow inbound and outbound HTTP and HTTPS access from anywhere.

Note that if you plan to launch instances in multiple AWS Regions, you'll need to create a security group in each Region. For more information about Regions, see [Regions and Zones \(p. 1221\)](#).

Prerequisites

You'll need the public IPv4 address of your local computer. The security group editor in the Amazon EC2 console can automatically detect the public IPv4 address for you. Alternatively, you can use the search phrase "what is my IP address" in an internet browser, or use the following service: [Check IP](#). If you are connecting through an Internet service provider (ISP) or from behind a firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

You can create a custom security group using one of the following methods.

New console

To create a security group with least privilege

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the top navigation bar, select an AWS Region for the security group. Security groups are specific to a Region, so you should select the same Region in which you created your key pair.
3. In the left navigation pane, choose **Security Groups**.
4. Choose **Create security group**.
5. For **Basic details**, do the following:
 - a. Enter a name for the new security group and a description. Use a name that is easy for you to remember, such as your user name, followed by _SG_, plus the Region name. For example, *me_SG_uswest2*.
 - b. In the **VPC** list, select your default VPC for the Region.
6. For **Inbound rules**, create rules that allow specific traffic to reach your instance. For example, use the following rules for a web server that accepts HTTP and HTTPS traffic. For more examples, see [Security group rules for different use cases \(p. 1687\)](#).
 - a. Choose **Add rule**. For **Type**, choose **HTTP**. For **Source**, choose **Anywhere**.
 - b. Choose **Add rule**. For **Type**, choose **HTTPS**. For **Source**, choose **Anywhere**.
 - c. Choose **Add rule**. For **Type**, choose **RDP**. For **Source**, do one of the following:
 - Choose **My IP** to automatically add the public IPv4 address of your local computer.
 - Choose **Custom** and specify the public IPv4 address of your computer or network in CIDR notation. To specify an individual IP address in CIDR notation, add the routing suffix /32, for example, 203.0.113.25/32. If your company or your router allocates addresses from a range, specify the entire range, such as 203.0.113.0/24.

Warning

For security reasons, do not choose **Anywhere** for **Source** with a rule for RDP. This would allow access to your instance from all IP addresses on the internet. This is acceptable for a short time in a test environment, but it is unsafe for production environments.

7. For **Outbound rules**, keep the default rule, which allows all outbound traffic.
8. Choose **Create security group**.

Old console

To create a security group with least privilege

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Security Groups**.
3. Choose **Create Security Group**.
4. Enter a name for the new security group and a description. Use a name that is easy for you to remember, such as your user name, followed by `_SG_` plus the Region name. For example, `me_SG_uswest2`.
5. In the **VPC** list, select your default VPC for the Region.
6. On the **Inbound rules** tab, create the following rules (choose **Add rule** for each new rule):
 - Choose **HTTP** from the **Type** list, and make sure that **Source** is set to **Anywhere (0.0.0.0/0)**.
 - Choose **HTTPS** from the **Type** list, and make sure that **Source** is set to **Anywhere (0.0.0.0/0)**.
 - Choose **RDP** from the **Type** list. In the **Source** box, choose **My IP** to automatically populate the field with the public IPv4 address of your local computer. Alternatively, choose **Custom** and specify the public IPv4 address of your computer or network in CIDR notation. To specify an individual IP address in CIDR notation, add the routing suffix `/32`, for example, `203.0.113.25/32`. If your company allocates addresses from a range, specify the entire range, such as `203.0.113.0/24`.

Warning

For security reasons, do not allow RDP access from all IP addresses to your instance. This is acceptable for a short time in a test environment, but it is unsafe for production environments.

7. On the **Outbound rules** tab, keep the default rule, which allows all outbound traffic.
8. Choose **Create security group**.

AWS CLI

When you use the AWS CLI to create a security group, an outbound rule that allows all outbound traffic is automatically added to the security group. An inbound rule isn't automatically added; you'll need to add it.

In this procedure, you'll combine the [create-security-group](#) and [authorize-security-group-ingress](#) AWS CLI commands to create the security group and add the inbound rule that allows the specified inbound traffic. An alternative to the following procedure is to run the commands separately, first creating a security group, and then adding an inbound rule to the security group.

To create a security group and add an inbound rule to the security group

Use the [create-security-group](#) and [authorize-security-group-ingress](#) AWS CLI commands as follows:

```
aws ec2 authorize-security-group-ingress \
--region us-west-2 \
--group-id $(aws ec2 create-security-group \
--group-name myname_SG_uswest2 \
--description "Security group description" \
--vpc-id vpc-12345678 \
--output text \
```

```
--region us-west-2) \
--ip-permissions \
IpProtocol=tcp,FromPort=80,ToPort=80,IpRanges='[{"CidrIp=0.0.0.0/0,Description="HTTP
from anywhere"}]' \
IpProtocol=tcp,FromPort=443,ToPort=443,IpRanges='[{"CidrIp=0.0.0.0/0,Description="HTTPS
from anywhere"}]' \
IpProtocol=tcp,FromPort=3389,ToPort=3389,IpRanges='[{"CidrIp=172.31.0.0/16,Description="RDP
from private network"}]' \
IpProtocol=tcp,FromPort=3389,ToPort=3389,IpRanges='[{"CidrIp=203.0.113.25/32,Description="RDP
from public IP"}]'
```

For:

- **--region** – Specify the Region in which to create the inbound rules.
- **--group-id** – Specify the `create-security-group` command and the following parameters to create the security group:
 - **--group-name** – Specify a name for the new security group. Use a name that is easy for you to remember, such as your user name, followed by `_SG_`, plus the Region name. For example, `myname_SG_uswest2`.
 - **--description** – Specify a description that will help you know what traffic the security group allows.
 - **--vpc-id** – Specify your default VPC for the Region.
 - **--output** – Specify text as the output format for the command.
 - **--region** – Specify the Region in which to create the security group. It should be the same Region that you specified for the inbound rules.
- **--ip-permissions** – Specify the inbound rules to add to the security group. The rules in this example are for a web server that accepts HTTP and HTTPS traffic from anywhere, and that accepts RDP traffic from a private network (if your company or your router allocates addresses from a range) and a specified public IP address (such as the public IPv4 address of your computer or network in CIDR notation).

Warning

For security reasons, do not specify `0.0.0.0/0` for `CidrIp` with a rule for RDP. This would allow access to your instance from all IP addresses on the internet. This is acceptable for a short time in a test environment, but it is unsafe for production environments.

PowerShell

When you use the AWS Tools for Windows PowerShell to create a security group, an outbound rule that allows all outbound traffic is automatically added to the security group. An inbound rule isn't automatically added; you'll need to add it.

In this procedure, you'll combine the [New-EC2SecurityGroup](#) and [Grant-EC2SecurityGroupIngress](#) AWS Tools for Windows PowerShell commands to create the security group and add the inbound rule that allows the specified inbound traffic. An alternative to the following procedure is to run the commands separately, first creating a security group, and then adding an inbound rule to the security group.

To create a security group

Use the [New-EC2SecurityGroup](#) and [Grant-EC2SecurityGroupIngress](#) AWS Tools for Windows PowerShell commands as follows.

```
Import-Module AWS.Tools.EC2
New-EC2SecurityGroup -GroupName myname_SG_uswest2 -Description 'Security group
description' -VpcId vpc-12345678 -Region us-west-2 | `

    Grant-EC2SecurityGroupIngress `

        -GroupName $_ `

        -Region us-west-2 `

        -IpPermission @(`

            (New-Object -TypeName Amazon.EC2.Model.IpPermission -Property @{
                IpProtocol = 'tcp';
                FromPort   = 80;
                ToPort     = 80;
                Ipv4Ranges = @(@{CidrIp = '0.0.0.0/0'; Description = 'HTTP from
anywhere'})
            }),
            (New-Object -TypeName Amazon.EC2.Model.IpPermission -Property @{
                IpProtocol = 'tcp';
                FromPort   = 443;
                ToPort     = 443;
                Ipv4Ranges = @(@{CidrIp = '0.0.0.0/0'; Description = 'HTTPS from
anywhere'})
            }),
            (New-Object -TypeName Amazon.EC2.Model.IpPermission -Property @{
                IpProtocol = 'tcp';
                FromPort   = 3389;
                ToPort     = 3389;
                Ipv4Ranges = @(
                    @{CidrIp = '172.31.0.0/16'; Description = 'RDP from private
network'},
                    @{CidrIp = '203.0.113.25/32'; Description = 'RDP from public IP'}
                )
            })
        )
    )
```

For the security group:

- **-GroupName** – Specify a name for the new security group. Use a name that is easy for you to remember, such as your user name, followed by `_SG_`, plus the Region name. For example, `myname_SG_uswest2`.
- **-Description** – Specify a description that will help you know what traffic the security group allows.
- **-VpcId** – Specify your default VPC for the Region.
- **-Region** – Specify the Region in which to create the security group.

For the inbound rules:

- **-GroupName** – Specify `$_` to reference the security group you're creating.
- **-Region** – Specify the Region in which to create the inbound rules. It should be the same Region that you specified for the security group.
- **-IpPermission** – Specify the inbound rules to add to the security group. The rules in this example are for a web server that accepts HTTP and HTTPS traffic from anywhere, and that accepts RDP traffic from a private network (if your company or your router allocates addresses from a range) and a specified public IP address (such as the public IPv4 address of your computer or network in CIDR notation).

Warning

For security reasons, do not specify `0.0.0.0/0` for `CidrIp` with a rule for RDP. This would allow access to your instance from all IP addresses on the internet. This is acceptable for a short time in a test environment, but it is unsafe for production environments.

For more information, see [Amazon EC2 security groups for Windows instances \(p. 1674\)](#).

Tutorial: Get started with Amazon EC2 Windows instances

Use this tutorial to get started with Amazon Elastic Compute Cloud (Amazon EC2). You'll learn how to launch, connect to, and use a Windows instance. An *instance* is a virtual server in the AWS Cloud. With Amazon EC2, you can set up and configure the operating system and applications that run on your instance.

When you sign up for AWS, you can get started with Amazon EC2 using the [AWS Free Tier](#). If you created your AWS account less than 12 months ago, and have not already exceeded the free tier benefits for Amazon EC2, it won't cost you anything to complete this tutorial because we help you select options that are within the free tier benefits. Otherwise, you'll incur the standard Amazon EC2 usage fees from the time that you launch the instance until you terminate the instance (which is the final task of this tutorial), even if it remains idle.

Related tutorials

- If you'd prefer to launch a Linux instance, see this tutorial in the *Amazon EC2 User Guide for Linux Instances*: [Get started with Amazon EC2 Linux instances](#).
- If you'd prefer to use the command line, see this tutorial in the *AWS Command Line Interface User Guide*: [Using Amazon EC2 through the AWS CLI](#).

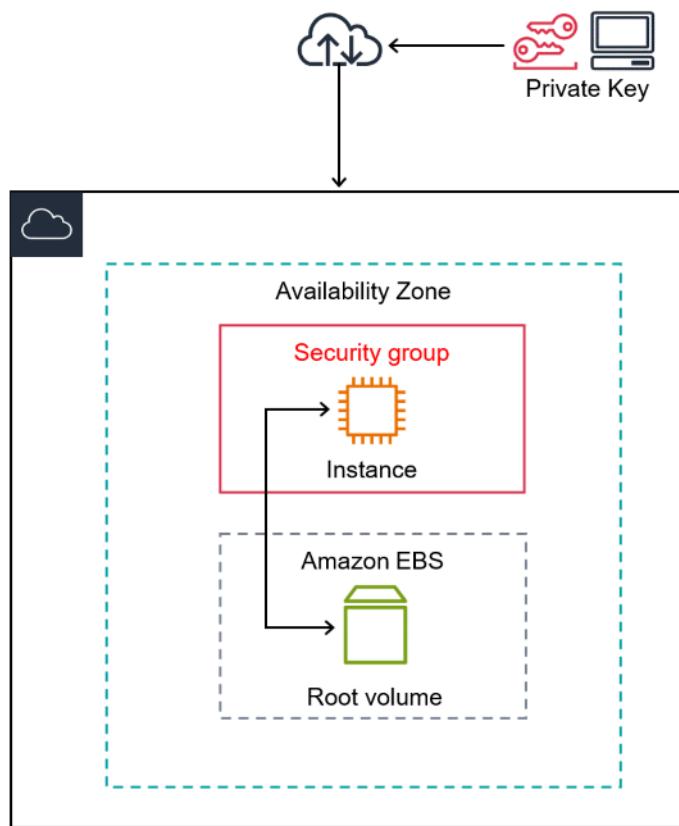

Contents

- [Overview \(p. 14\)](#)
- [Prerequisites \(p. 15\)](#)
- [Step 1: Launch an instance \(p. 15\)](#)
- [Step 2: Connect to your instance \(p. 16\)](#)
- [Step 3: Clean up your instance \(p. 22\)](#)
- [Next steps \(p. 22\)](#)

Overview

The instance launched in this tutorial is an Amazon EBS-backed instance (meaning that the root volume is an EBS volume). You can either specify the Availability Zone in which your instance runs, or let Amazon EC2 select an Availability Zone for you. Availability Zones are multiple, isolated locations within each Region. You can think of an Availability Zone as an isolated data center.

When you launch your instance, you secure it by specifying a key pair (to prove your identity) and a security group (which acts as a virtual firewall to control ingoing and outgoing traffic). When you connect to your instance, you must provide the private key of the key pair that you specified when you launched your instance.

Prerequisites

Before you begin, be sure that you've completed the steps in [Set up to use Amazon EC2 \(p. 7\)](#).

Step 1: Launch an instance

You can launch a Windows instance using the AWS Management Console as described in the following procedure. This tutorial is intended to help you quickly launch your first instance, so it doesn't cover all possible options. For information about advanced options, see [Launch an instance using the new launch instance wizard \(p. 552\)](#). For information about other ways to launch your instance, see [Launch your instance \(p. 551\)](#).

To launch an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the EC2 console dashboard, in the **Launch instance** box, choose **Launch instance**, and then choose **Launch instance** from the options that appear.
3. Under **Name and tags**, for **Name**, enter a descriptive name for your instance.
4. Under **Application and OS Images (Amazon Machine Image)**, do the following:
 - a. Choose **Quick Start**, and then choose Windows. This is the operating system (OS) for your instance.

- b. From **Amazon Machine Image (AMI)**, select the AMI for Windows Server 2016 Base or later.. Notice that these AMIs are marked **Free tier eligible**. An *Amazon Machine Image (AMI)* is a basic configuration that serves as a template for your instance.
5. Under **Instance type**, from the **Instance type** list, you can select the hardware configuration for your instance. Choose the t2.micro instance type, which is selected by default. The t2.micro instance type is eligible for the free tier. In Regions where t2.micro is unavailable, you can use a t3.micro instance under the free tier. For more information, see [AWS Free Tier](#).
6. Under **Key pair (login)**, for **Key pair name**, choose the key pair that you created when getting set up. Note that you must select an **RSA** key. **ED25519** keys are not supported for Windows instances.

Warning

Do not choose **Proceed without a key pair (Not recommended)**. If you launch your instance without a key pair, then you can't connect to it.

7. Next to **Network settings**, choose **Edit**. For **Security group name**, you'll see that the wizard created and selected a security group for you. You can use this security group, or alternatively you can select the security group that you created when getting set up using the following steps:
 - a. Choose **Select existing security group**.
 - b. From **Common security groups**, choose your security group from the list of existing security groups.
8. Keep the default selections for the other configuration settings for your instance.
9. Review a summary of your instance configuration in the **Summary** panel, and when you're ready, choose **Launch instance**.
10. A confirmation page lets you know that your instance is launching. Choose **View all instances** to close the confirmation page and return to the console.
11. On the **Instances** screen, you can view the status of the launch. It takes a short time for an instance to launch. When you launch an instance, its initial state is pending. After the instance starts, its state changes to running and it receives a public DNS name. If the **Public IPv4 DNS** column is hidden, choose the settings icon () in the top-right corner, toggle on **Public IPv4 DNS**, and choose **Confirm**.
12. It can take a few minutes for the instance to be ready for you to connect to it. Check that your instance has passed its status checks; you can view this information in the **Status check** column.

Step 2: Connect to your instance

To connect to a Windows instance, you must retrieve the initial administrator password and then enter this password when you connect to your instance using Remote Desktop. It takes a few minutes after instance launch before this password is available.

The name of the administrator account depends on the language of the operating system. For example, for English, it's **Administrator**; for French it's **Administrateur**, and for Portuguese it's **Administrador**. For more information, see [Localized Names for Administrator Account in Windows](#) in the Microsoft TechNet Wiki.

If you've joined your instance to a domain, you can connect to your instance using domain credentials you've defined in AWS Directory Service. On the Remote Desktop login screen, instead of using the local computer name and the generated password, use the fully-qualified user name for the administrator (for example, **corp.example.com\Admin**), and the password for this account.

If you receive an error while attempting to connect to your instance, see [Remote Desktop can't connect to the remote computer \(p. 2119\)](#).

New console

To connect to your Windows instance using an RDP client

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, select **Instances**. Select the instance and then choose **Connect**.
3. On the **Connect to instance** page, choose the **RDP client** tab, and then choose **Get password**.

The screenshot shows the 'Connect to instance' page with the 'RDP client' tab selected. At the top, it says 'Connect to your instance i- [REDACTED] (Source-NET-Webserver) using any of these options'. Below that, there are three tabs: 'Session Manager', 'RDP client' (which is highlighted in orange), and 'EC2 serial console'. Under 'Instance ID', it shows 'i- [REDACTED] (Source-NET-Webserver)'. The 'Connection Type' section contains two options: 'Connect using RDP client' (selected) and 'Connect using Fleet Manager'. A callout box points to the 'Get password' link under the RDP client option. Below this, a note says 'You can connect to your Windows instance using a remote desktop client of your choice, and by downloading and running the RDP shortcut file below:' followed by a 'Download remote desktop file' button. Further down, it asks 'When prompted, connect to your instance using the following details:' and provides fields for 'Public DNS' (set to 'ec2-[REDACTED].us-west-2.compute.amazonaws.com') and 'User name' ('Administrator'). At the bottom, a note says 'If you've joined your instance to a directory, you can use your directory credentials to connect to your instance.' A 'Cancel' button is at the very bottom right.

4. Choose **Browse** and navigate to the private key (. pem) file you created when you launched the instance. Select the file and choose **Open** to copy the entire contents of the file to this window.
5. Choose **Decrypt Password**. The console displays the default administrator password for the instance under **Password**, replacing the **Get password** link shown previously. Save the password in a safe place. This password is required to connect to the instance.

Connect to instance [Info](#)

Connect to your instance [REDACTED] using any of these options

Session Manager | **RDP client** | EC2 Serial Console

⚠ You may not be able to connect to this instance as ports 3389 may need to be open in order to be accessible. The current associated security groups don't have ports 3389 open. **X**

You can connect to your Windows instance using a remote desktop client of your choice, and by downloading and running the RDP shortcut file below:

[Download remote desktop file](#)

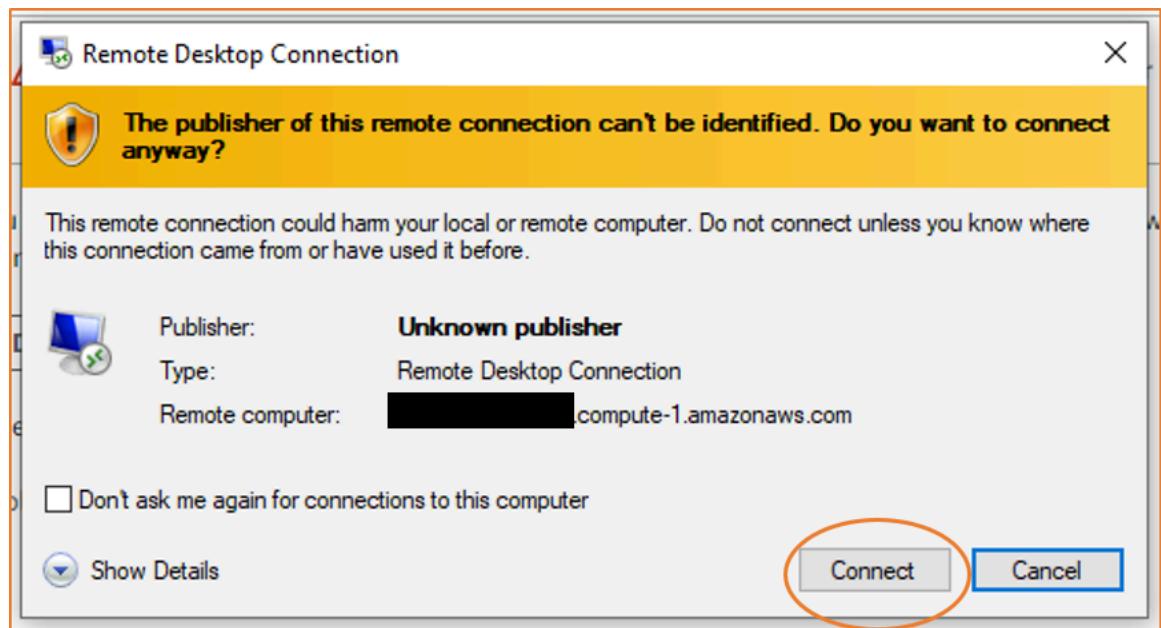

When prompted, connect to your instance using the following details:

Public DNS	User name
<input type="text"/> [REDACTED].compute-1.amazonaws.com	<input type="text"/> Administrator
Password	
<input type="password"/> [REDACTED]	

If you've joined your instance to a directory, you can use your directory credentials to connect to your instance.

Cancel

6. Choose **Download remote desktop file**. Your browser prompts you to either open or save the RDP shortcut file. When you have finished downloading the file, choose **Cancel** to return to the **Instances** page.
 - If you opened the RDP file, you'll see the **Remote Desktop Connection** dialog box.
 - If you saved the RDP file, navigate to your downloads directory, and open the RDP file to display the dialog box.
7. You may get a warning that the publisher of the remote connection is unknown. Choose **Connect** to continue to connect to your instance.

8. The administrator account is chosen by default. Copy and paste the password that you saved previously.

Tip

If you receive a "Password Failed" error, try entering the password manually. Copying and pasting content can corrupt it.

9. Due to the nature of self-signed certificates, you may get a warning that the security certificate could not be authenticated. Use the following steps to verify the identity of the remote computer, or simply choose **Yes** (Windows) or **Continue** (Mac OS X) if you trust the certificate.

- a. If you are using **Remote Desktop Connection** on a Windows computer, choose **View certificate**. If you are using **Microsoft Remote Desktop** on a Mac, choose **Show Certificate**.
- b. Choose the **Details** tab, and scroll down to **Thumbprint** (Windows) or **SHA1 Fingerprints** (Mac OS X). This is the unique identifier for the remote computer's security certificate.
- c. In the Amazon EC2 console, select the instance, choose **Actions, Monitor and troubleshoot, Get system log**.
- d. In the system log output, look for **RDPMESSAGE - THUMBPRINT**. If this value matches the thumbprint or fingerprint of the certificate, you have verified the identity of the remote computer.
- e. If you are using **Remote Desktop Connection** on a Windows computer, return to the **Certificate** dialog box and choose **OK**. If you are using **Microsoft Remote Desktop** on a Mac, return to the **Verify Certificate** and choose **Continue**.
- f. [Windows] Choose **Yes** in the **Remote Desktop Connection** window to connect to your instance.

[Mac OS X] Log in as prompted, using the default administrator account and the default administrator password that you recorded or copied previously. Note that you might need to switch spaces to see the login screen. For more information, see [Add spaces and switch between them](#).

Old console

To connect to your Windows instance using an RDP client

1. In the Amazon EC2 console, select the instance, and then choose **Connect**.
2. In the **Connect To Your Instance** dialog box, choose **Get Password** (it will take a few minutes after the instance is launched before the password is available).
3. Choose **Browse** and navigate to the private key (.pem) file you created when you launched the instance. Select the file and choose **Open** to copy the entire contents of the file into the **Contents** field.
4. Choose **Decrypt Password**. The console displays the default administrator password for the instance in the **Connect To Your Instance** dialog box, replacing the link to **Get Password** shown previously with the actual password.
5. Record the default administrator password, or copy it to the clipboard. You need this password to connect to the instance.
6. Choose **Download Remote Desktop File**. Your browser prompts you to either open or save the .rdp file. Either option is fine. When you have finished, you can choose **Close** to dismiss the **Connect To Your Instance** dialog box.
 - If you opened the .rdp file, you'll see the **Remote Desktop Connection** dialog box.
 - If you saved the .rdp file, navigate to your downloads directory, and open the .rdp file to display the dialog box.
7. You may get a warning that the publisher of the remote connection is unknown. You can continue to connect to your instance.
8. When prompted, log in to the instance, using the administrator account for the operating system and the password that you recorded or copied previously. If your **Remote Desktop Connection** already has an administrator account set up, you might have to choose the **Use another account** option and type the user name and password manually.

Note

Sometimes copying and pasting content can corrupt data. If you encounter a "Password Failed" error when you log in, try typing in the password manually.

9. Due to the nature of self-signed certificates, you may get a warning that the security certificate could not be authenticated. Use the following steps to verify the identity of the remote computer, or simply choose **Yes** or **Continue** to continue if you trust the certificate.
 - a. If you are using **Remote Desktop Connection** from a Windows PC, choose **View certificate**. If you are using **Microsoft Remote Desktop** on a Mac, choose **Show Certificate**.
 - b. Choose the **Details** tab, and scroll down to the **Thumbprint** entry on a Windows PC, or the **SHA1 Fingerprints** entry on a Mac. This is the unique identifier for the remote computer's security certificate.
 - c. In the Amazon EC2 console, select the instance, choose **Actions**, and then choose **Get System Log**.
 - d. In the system log output, look for an entry labeled RDPCERTIFICATE-THUMBPRINT. If this value matches the thumbprint or fingerprint of the certificate, you have verified the identity of the remote computer.
 - e. If you are using **Remote Desktop Connection** from a Windows PC, return to the **Certificate** dialog box and choose **OK**. If you are using **Microsoft Remote Desktop** on a Mac, return to the **Verify Certificate** and choose **Continue**.
 - f. [Windows] Choose **Yes** in the **Remote Desktop Connection** window to connect to your instance.

[Mac OS] Log in as prompted, using the default administrator account and the default administrator password that you recorded or copied previously. Note that you might

need to switch spaces to see the login screen. For more information about spaces, see support.apple.com/en-us/HT204100.

- g. If you receive an error while attempting to connect to your instance, see [Remote Desktop can't connect to the remote computer \(p. 2119\)](#).

Step 3: Clean up your instance

After you've finished with the instance that you created for this tutorial, you should clean up by terminating the instance. If you want to do more with this instance before you clean up, see [Next steps \(p. 22\)](#).

Important

Terminating an instance effectively deletes it; you can't reconnect to an instance after you've terminated it.

If you launched an instance that is not within the [AWS Free Tier](#), you'll stop incurring charges for that instance as soon as the instance status changes to shutting down or terminated. To keep your instance for later, but not incur charges, you can stop the instance now and then start it again later. For more information, see [Stop and start your instance \(p. 594\)](#).

To terminate your instance

1. In the navigation pane, choose **Instances**. In the list of instances, select the instance.
2. Choose **Instance state, Terminate instance**.
3. Choose **Terminate** when prompted for confirmation.

Amazon EC2 shuts down and terminates your instance. After your instance is terminated, it remains visible on the console for a short while, and then the entry is automatically deleted. You cannot remove the terminated instance from the console display yourself.

Next steps

After you start your instance, you might want to try some of the following exercises:

- Learn how to remotely manage your EC2 instance using Run Command. For more information, see [AWS Systems Manager Run Command](#) in the [AWS Systems Manager User Guide](#).
- Configure a CloudWatch alarm to notify you if your usage exceeds the Free Tier. For more information, see [Tracking your AWS Free Tier usage](#) in the [AWS Billing User Guide](#).
- Add an EBS volume. For more information, see [Create an Amazon EBS volume \(p. 1726\)](#) and [Attach an Amazon EBS volume to an instance \(p. 1729\)](#).
- Learn about instance purchasing options. For more information, see [Instance purchasing options \(p. 349\)](#).

Best practices for Windows on Amazon EC2

To ensure the best results from running Windows on Amazon EC2, we recommend that you perform the following best practices.

- [Update drivers](#)
- [Use the latest Windows AMIs](#)
- [Security](#)
- [Storage](#)
- [Resource management](#)
- [Backup and recovery](#)
- [Networking](#)

Update Windows drivers

Maintain the latest drivers on all Windows EC2 instances to ensure that the latest issue fixes and performance enhancements are applied across your fleet. Depending on your instance type, you should update the [AWS PV \(p. 780\)](#), [Amazon ENA \(p. 1327\)](#), and [AWS NVMe \(p. 799\)](#) drivers.

- Use [SNS topics](#) to receive updates for new driver releases.
- Use the AWS Systems Manager Automation runbook [AWSSupport-UpgradeWindowsAWSDrivers](#) to easily apply the updates across your instances.

Launch new instances with the latest Windows AMIs

AWS releases new [Windows AMIs](#) each month, which contain the latest OS patches, drivers, and launch agents. You should leverage the latest AMI when you launch new instances or when you build your own custom images.

- To view updates to each release of the AWS Windows AMIs, see [AWS Windows AMI version history](#).
- To build with the latest available AMIs, see [Query for the Latest Windows AMI Using Systems Manager Parameter Store](#).

Test system/application performance before migration

Migrating enterprise applications to AWS can involve many variables and configurations. Always performance test the EC2 solution to ensure that:

- Instance types are properly configured, including instance size, enhanced networking, and tenancy (shared or dedicated).
- Instance topology is appropriate for the workload and leverages high-performance features when necessary, such as dedicated tenancy, placement groups, instance store volumes, and bare metal.

Update launch agents

Update to the latest EC2Launch v2 agent to ensure that the latest enhancements are applied across your fleet. If you have a mixed fleet, or if you want to continue to use the EC2Launch (Windows Server 2016 and 2019) or EC2 Config (Windows Server 2012 R2 and earlier) agents, update to the latest versions of the respective agents.

Automatic updates are supported on the following combinations of Windows Server version and launch agents. You can opt in to automatic updates in the [SSM Quick Setup Host Management](#) console under **Amazon EC2 Launch Agents**.

Windows Version	EC2Config	EC2Launch v1	EC2Launch v2
2012	✓		✓
2012 R2	✓		✓
2016		✓	✓
2019		✓	✓
2022			✓

- For more information about updating to EC2Launch v2, see [Install the latest version of EC2Launch v2](#).
- For information to manually update EC2Config, see [Install the Latest Version of EC2Config](#).
- For information to manually update EC2Launch, see [Install the Latest Version of EC2Launch](#).

Security

When securing Windows instances, we recommend that you implement Active Directory Domain Services to enable a scalable, secure, and manageable infrastructure for distributed locations. Additionally, after launching instances from the Amazon EC2 console or by using an Amazon EC2 provisioning tool, such as AWS CloudFormation, it is good practice to utilize native OS features, such as [Microsoft Windows PowerShell DSC](#) to maintain configuration state in the event that configuration drift occurs.

Windows instances in AWS should adhere to the following high-level security best practices:

- **Least Access:** Grant access only to systems and locations that are trusted and expected. This applies to all Microsoft products such as Active Directory, Microsoft business productivity servers, and infrastructure services such as Remote Desktop Services, reverse proxy servers, IIS web servers, and more. Use AWS capabilities such as Amazon EC2 instance security groups, network access control lists (ACLs), and Amazon VPC public/private subnets to layer security across multiple locations in an architecture. Within a Windows instance, customers can use Windows Firewall to further layer a defense-in-depth strategy within their deployment. Install only the OS components and applications that are necessary for the system to function as designed. Configure infrastructure services such as IIS to run under service accounts, or to use features such as application pool identities to access resources locally and remotely across your infrastructure.
- **Least Privilege:** Determine the minimum set of privileges that instances and accounts need in order to perform their functions. Restrict these servers and users to only allow these defined permissions. Use techniques such as Role Based Access Controls to reduce the surface area of administrative accounts, and create the most limited roles to accomplish a task. Use OS features such as Encrypting File System (EFS) within NTFS to encrypt sensitive data at rest, and control application and user access to it.
- **Configuration Management:** Create a baseline server configuration that incorporates up-to-date security patches and host-based protection suites that include anti-virus, anti-malware, intrusion detection/prevention, and file integrity monitoring. Assess each server against the current recorded baseline to identify and flag any deviations. Ensure each server is configured to generate and securely store appropriate log and audit data. For more information, see [AWS Windows AMIs](#).

- **Change Management:** Create processes to control changes to server configuration baselines and work toward fully automated change processes. Also, leverage Just Enough Administration (JEA) with Windows PowerShell DSC to limit administrative access to the minimum required functions.
- **Patch Management:** Implement processes that regularly patch, update, and secure the operating system and applications on your EC2 instances. For more information, see [Update your Windows instance \(p. 60\)](#).
- **Audit Logs:** Audit access and all changes to Amazon EC2 instances to verify server integrity and ensure only authorized changes are made. Leverage features such as [Enhanced Logging for IIS](#) to enhance default logging capabilities. AWS capabilities such as VPC Flow Logs and AWS CloudTrail are also available to audit network access, including allowed/denied requests and API calls, respectively.

Use AWS Security Hub controls to monitor your Amazon EC2 resources against security best practices and security standards. For more information about using Security Hub, see [Amazon Elastic Compute Cloud controls](#) in the *AWS Security Hub User Guide*.

Storage

- Use separate Amazon EBS volumes for the operating system versus your data. Ensure that the volume with your data persists after instance termination. For more information, see [Preserve Amazon EBS volumes on instance termination \(p. 620\)](#).
- Use the instance store available for your instance to store temporary data. Remember that the data stored in instance store is deleted when you stop, hibernate, or terminate your instance. If you use instance store for database storage, ensure that you have a cluster with a replication factor that ensures fault tolerance.
- Encrypt EBS volumes and snapshots. For more information, see [Amazon EBS encryption \(p. 1921\)](#).

Resource management

- Use instance metadata and custom resource tags to track and identify your AWS resources. For more information, see [Instance metadata and user data \(p. 862\)](#) and [Tag your Amazon EC2 resources \(p. 2085\)](#).
- View your current limits for Amazon EC2. Plan to request any limit increases in advance of the time that you'll need them. For more information, see [Amazon EC2 service quotas \(p. 2100\)](#).
- Use AWS Trusted Advisor to inspect your AWS environment, and then make recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. For more information, see [AWS Trusted Advisor](#) in the *AWS Support User Guide*.

Backup and recovery

- Regularly back up your EBS volumes using [Amazon EBS snapshots \(p. 1757\)](#), and create an [Amazon Machine Image \(AMI\) \(p. 28\)](#) from your instance to save the configuration as a template for launching future instances. For more information on AWS services that help achieve this use case, see [AWS Backup](#) and [Amazon Data Lifecycle Manager](#).
- Deploy critical components of your application across multiple Availability Zones, and replicate your data appropriately.
- Design your applications to handle dynamic IP addressing when your instance restarts. For more information, see [Amazon EC2 instance IP addressing \(p. 1235\)](#).
- Monitor and respond to events. For more information, see [Monitor Amazon EC2 \(p. 1150\)](#).
- Ensure that you are prepared to handle failover. For a basic solution, you can manually attach a network interface or Elastic IP address to a replacement instance. For more information, see [Elastic network interfaces \(p. 1280\)](#). For an automated solution, you can use Amazon EC2 Auto Scaling. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).

- Regularly test the process of recovering your instances and Amazon EBS volumes to ensure data and services are restored successfully.

Networking

- Set the time-to-live (TTL) value for your applications to 255, for IPv4 and IPv6. If you use a smaller value, there is a risk that the TTL will expire while application traffic is in transit, causing reachability issues for your instances.

Using this service with an AWS SDK

AWS software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

SDK documentation	Code examples
AWS SDK for C++	AWS SDK for C++ code examples
AWS SDK for Go	AWS SDK for Go code examples
AWS SDK for Java	AWS SDK for Java code examples
AWS SDK for JavaScript	AWS SDK for JavaScript code examples
AWS SDK for Kotlin	AWS SDK for Kotlin code examples
AWS SDK for .NET	AWS SDK for .NET code examples
AWS SDK for PHP	AWS SDK for PHP code examples
AWS SDK for Python (Boto3)	AWS SDK for Python (Boto3) code examples
AWS SDK for Ruby	AWS SDK for Ruby code examples
AWS SDK for Rust	AWS SDK for Rust code examples
AWS SDK for Swift	AWS SDK for Swift code examples

Example availability

Can't find what you need? Request a code example by using the **Provide feedback** link at the bottom of this page.

Amazon Machine Images (AMI)

An Amazon Machine Image (AMI) is a supported and maintained image provided by AWS that provides the information required to launch an instance. You must specify an AMI when you launch an instance. You can launch multiple instances from a single AMI when you require multiple instances with the same configuration. You can use different AMIs to launch instances when you require instances with different configurations.

An AMI includes the following:

- One or more Amazon Elastic Block Store (Amazon EBS) snapshots, or, for instance-store-backed AMIs, a template for the root volume of the instance (for example, an operating system, an application server, and applications).
- Launch permissions that control which AWS accounts can use the AMI to launch instances.
- A block device mapping that specifies the volumes to attach to the instance when it's launched.

Amazon Machine Image (AMI) topics

- [Boot modes \(p. 28\)](#)
- [AWS Windows AMIs \(p. 41\)](#)
- [Find a Windows AMI \(p. 123\)](#)
- [Shared AMIs \(p. 129\)](#)
- [Paid AMIs \(p. 147\)](#)
- [AMI lifecycle \(p. 151\)](#)
- [Use encryption with EBS-backed AMIs \(p. 193\)](#)
- [Monitor AMI events using Amazon EventBridge \(p. 197\)](#)
- [Understand AMI billing information \(p. 201\)](#)
- [AMI quotas \(p. 205\)](#)

Boot modes

When a computer boots, the first software that it runs is responsible for initializing the platform and providing an interface for the operating system to perform platform-specific operations.

In Amazon EC2, two variants of the boot mode software are supported: Unified Extensible Firmware Interface (UEFI) and Legacy BIOS.

Possible boot mode parameters on an AMI

An AMI can have one of the following boot mode parameter values: `uefi`, `legacy-bios`, or `uefi-preferred`. The AMI boot mode parameter is optional. For AMIs with no boot mode parameter, the instances launched from these AMIs use the default boot mode value of the instance type.

Purpose of the AMI boot mode parameter

The AMI boot mode parameter signals to Amazon EC2 which boot mode to use when launching an instance. When the boot mode parameter is set to `uefi`, EC2 attempts to launch the instance on UEFI. If the operating system is not configured to support UEFI, the instance launch will be unsuccessful.

UEFI Preferred boot mode parameter

You can create AMIs that support both UEFI and Legacy BIOS by using the `uefi-preferred` boot mode parameter. When the boot mode parameter is set to `uefi-preferred`, and if the instance type supports UEFI, the instance is launched on UEFI. If the instance type does not support UEFI, the instance is launched on Legacy BIOS.

Warning

Some features, like UEFI Secure Boot, are only available on instances that boot on UEFI. When you use the `uefi-preferred` AMI boot mode parameter with an instance type that does not support UEFI, the instance will launch as Legacy BIOS and the UEFI-dependent feature will be disabled. If you rely on the availability of a UEFI-dependent feature, set your AMI boot mode parameter to `uefi`.

Default boot modes for instance types

- Graviton instance types: UEFI
- Intel and AMD instance types: Legacy BIOS

Running Intel and AMD instances types on UEFI

[Most Intel and AMD instance types](#) can run on both UEFI and Legacy BIOS. To use UEFI, you must select an AMI with the boot mode parameter set either to `uefi` or `uefi-preferred`, and the operating system contained in the AMI must be configured to support UEFI.

Boot mode topics

- [Launch an instance \(p. 29\)](#)
- [Determine the boot mode parameter of an AMI \(p. 32\)](#)
- [Determine the supported boot modes of an instance type \(p. 32\)](#)
- [Determine the boot mode of an instance \(p. 33\)](#)
- [Determine the boot mode of the operating system \(p. 34\)](#)
- [Set the boot mode of an AMI \(p. 35\)](#)
- [UEFI variables \(p. 38\)](#)
- [UEFI Secure Boot \(p. 38\)](#)

Launch an instance

You can launch an instance in UEFI or Legacy BIOS boot mode.

Topics

- [Limitations \(p. 29\)](#)
- [Considerations \(p. 29\)](#)
- [Requirements for launching an instance on UEFI \(p. 31\)](#)

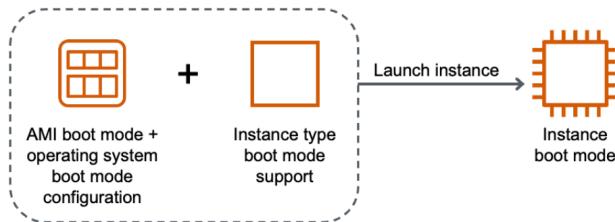

Limitations

UEFI boot is not supported in Local Zones, Wavelength Zones, or with AWS Outposts.

Considerations

Consider the following when launching an instance:

- The boot mode of the instance is determined by the configuration of the AMI, the operating system contained in it, and the instance type, illustrated by the following image:

The following table shows that the boot mode of an instance (indicated by the **Resulting instance boot mode** column) is determined by a combination of the boot mode parameter of the AMI (column 1), the boot mode configuration of the operating system contained in the AMI (column 2), and the boot mode support of the instance type (column 3).

AMI boot mode parameter	Operating system boot mode configuration	Instance type boot mode support	Resulting instance boot mode
UEFI	UEFI	UEFI	UEFI
Legacy BIOS	Legacy BIOS	Legacy BIOS	Legacy BIOS
UEFI Preferred	UEFI	UEFI	UEFI
UEFI Preferred	UEFI	UEFI and Legacy BIOS	UEFI
UEFI Preferred	Legacy BIOS	Legacy BIOS	Legacy BIOS
UEFI Preferred	Legacy BIOS	UEFI and Legacy BIOS	Legacy BIOS
No boot mode specified - ARM	UEFI	UEFI	UEFI
No boot mode specified - x86	Legacy BIOS	UEFI and Legacy BIOS	Legacy BIOS

- Default boot modes:
 - Graviton instance types: UEFI
 - Intel and AMD instance types: Legacy BIOS
- Intel and AMD instance types that support UEFI, in addition to Legacy BIOS:
 - All instances built on the AWS Nitro System, except: bare metal instances, DL1, G4ad, P4, u-3tb1, u-6tb1, u-9tb1, u-12tb1, u-18tb1, u-24tb1, and VT1

To see the available instance types that support UEFI in a specific Region

The available instance types vary by AWS Region. To see the available instance types that support UEFI in a Region, use the [describe-instance-types](#) command with the `--region` parameter. If you omit the `--region` parameter, your [default Region](#) is used in the request. Include the `--filters` parameter to scope the results to the instance types that support UEFI and the `--query` parameter to scope the output to the value of `InstanceType`.

```
aws ec2 describe-instance-types --filters Name=supported-boot-mode,Values=uefi --query "InstanceTypes[*].[InstanceType]" --output text | sort
```

Example output

```
a1.2xlarge
a1.4xlarge
a1.large
a1.medium
...
```

To see the available instance types that support UEFI Secure Boot and persist non-volatile variables in a specific Region

Currently, bare metal instances do not support UEFI Secure Boot and non-volatile variables. Use the [describe-instance-types](#) command as described in the preceding example, but filter out the bare metal instances by including the Name=hypervisor,Values=nitro filter. For information about UEFI Secure Boot, see [UEFI Secure Boot \(p. 38\)](#).

```
aws ec2 describe-instance-types --filters Name=supported-boot-mode,Values=uefi
Name=hypervisor,Values=nitro --query "InstanceTypes[*].[InstanceType]" --output text | sort
```

Requirements for launching an instance on UEFI

To launch an instance in UEFI boot mode, you must select an instance type that supports UEFI, and configure the AMI and the operating system for UEFI, as follows:

Instance type

When launching an instance, you must select an instance type that supports UEFI. For more information, see [Determine the supported boot modes of an instance type \(p. 32\)](#).

AMI

When launching an instance, you must select an AMI that is configured for UEFI. The AMI must be configured as follows:

- **Operating system** – The operating system contained in the AMI must be configured to use UEFI; otherwise, the instance launch will fail. For more information, see [Determine the boot mode of the operating system \(p. 34\)](#).
- **AMI boot mode parameter** – The boot mode parameter of the AMI must be set to uefi or uefi-preferred. For more information, see [Determine the boot mode parameter of an AMI \(p. 32\)](#).

The following Windows AMIs support UEFI:

- TPM-Windows_Server-2022-English-Full-Base
- TPM-Windows_Server-2022-English-Core-Base
- TPM-Windows_Server-2019-English-Full-Base
- TPM-Windows_Server-2019-English-Core-Base
- TPM-Windows_Server-2016-English-Full-Base
- TPM-Windows_Server-2016-English-Core-Base

For information about Linux AMIs, see [Requirements for launching an instance on UEFI](#) in the *Amazon EC2 User Guide for Linux Instances*.

Determine the boot mode parameter of an AMI

The AMI boot mode parameter is optional. An AMI can have one of the following boot mode parameter values: uefi, legacy-bios, or uefi-preferred.

Some AMIs don't have a boot mode parameter. When an AMI has no boot mode parameter, the instances launched from the AMI use the default value of the instance type, which is uefi on Graviton, and legacy-bios on Intel and AMD instance types.

To determine the boot mode parameter of an AMI (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**, and then select the AMI.
3. On the **Details** tab, inspect the **Boot mode** field.

To determine the boot mode parameter of an AMI when launching an instance (console)

When launching an instance using the launch instance wizard, at the step to select an AMI, inspect the **Boot mode** field. For more information, see [Application and OS Images \(Amazon Machine Image\) \(p. 555\)](#).

To determine the boot mode parameter of an AMI (AWS CLI)

Use the [describe-images](#) command to determine the boot mode of an AMI.

```
aws ec2 describe-images --region us-east-1 --image-id ami-0abcdef1234567890
```

In the output, the **BootMode** field indicates the boot mode of the AMI. A value of **uefi** indicates that the AMI supports UEFI. A value of **uefi-preferred** indicates that the AMI supports both UEFI and Legacy BIOS.

Expected output

```
{
  "Images": [
    {
      ...
      ],
      "EnaSupport": true,
      "Hypervisor": "xen",
      "ImageOwnerAlias": "amazon",
      "Name": "UEFI_Boot_Mode_Enabled-Windows_Server-2016-English-Full-Base-2020.09.30",
      "RootDeviceName": "/dev/sda1",
      "RootDeviceType": "ebs",
      "SriovNetSupport": "simple",
      "VirtualizationType": "hvm",
      "BootMode": "uefi"
    }
  ]
}
```

Determine the supported boot modes of an instance type

You can use the AWS CLI to determine the supported boot modes of an instance type.

To determine the supported boot modes of an instance type

Use the [describe-instance-types](#) command to determine the supported boot modes of an instance type. By including the `--query` parameter, you can filter the output. In this example, the output is filtered to return only the supported boot modes.

The following example shows that `m5.2xlarge` supports both UEFI and Legacy BIOS boot modes.

```
aws ec2 describe-instance-types --region us-east-1 --instance-types m5.2xlarge --query "InstanceTypes[*].SupportedBootModes"
```

Expected output

```
[  
  [  
    "legacy-bios",  
    "uefi"  
  ]  
]
```

The following example shows that `t2.xlarge` supports only Legacy BIOS.

```
aws ec2 describe-instance-types --region us-east-1 --instance-types t2.xlarge --query "InstanceTypes[*].SupportedBootModes"
```

Expected output

```
[  
  [  
    "legacy-bios"  
  ]  
]
```

Determine the boot mode of an instance

The boot mode of an instance is displayed in the **Boot mode** field in the Amazon EC2 console, and by the `currentInstanceBootMode` parameter in the AWS CLI.

When an instance is launched, the value for its boot mode parameter is determined by the value of the boot mode parameter of the AMI used to launch it, as follows:

- An AMI with a boot mode parameter of `uefi` creates an instance with a `currentInstanceBootMode` parameter of `uefi`.
- An AMI with a boot mode parameter of `legacy-bios` creates an instance with a `currentInstanceBootMode` parameter of `legacy-bios`.
- An AMI with a boot mode parameter of `uefi-preferred` creates an instance with a `currentInstanceBootMode` parameter of `uefi` if the instance type supports UEFI; otherwise, it creates an instance with a `currentInstanceBootMode` parameter of `legacy-bios`.
- An AMI with no boot mode parameter value creates an instance with a `currentInstanceBootMode` parameter value that is dependent on whether the AMI architecture is ARM or x86 and the supported boot mode of the instance type. The default boot mode is `uefi` on Graviton instance types, and `legacy-bios` on Intel and AMD instance types.

To determine the boot mode of an instance (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Instances**, and then select your instance.
3. On the **Details** tab, inspect the **Boot mode** field.

To determine the boot mode of an instance (AWS CLI)

Use the [describe-instances](#) command to determine the boot mode of an instance. You can also determine the boot mode of the AMI that was used to create the instance.

```
aws ec2 describe-instances --region us-east-1 --instance-ids i-1234567890abcdef0
```

In the output, the following parameters describe the boot mode:

- **BootMode** – The boot mode of the AMI that was used to create the instance.
- **CurrentInstanceBootMode** – The boot mode that is used to boot the instance at launch or start.

Expected output

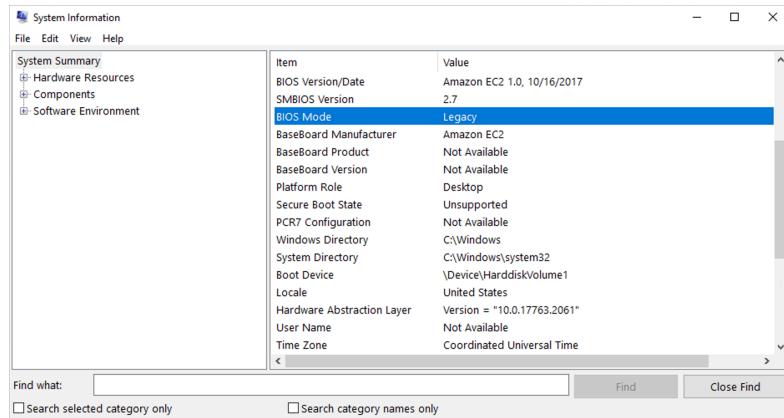

```
{  
    "Reservations": [  
        {  
            "Groups": [],  
            "Instances": [  
                {  
                    "AmiLaunchIndex": 0,  
                    "ImageId": "ami-0e2063e7f6dc3bee8",  
                    "InstanceId": "i-1234567890abcdef0",  
                    "InstanceType": "m5.2xlarge",  
                    ...  
                },  
                {  
                    "BootMode": "uefi",  
                    "CurrentInstanceBootMode": "uefi"  
                }  
            ],  
            "OwnerId": "1234567890",  
            "ReservationId": "r-1234567890abcdef0"  
        }  
    ]  
}
```

Determine the boot mode of the operating system

The boot mode of the AMI guides Amazon EC2 on which boot mode to use to boot an instance. To view whether the operating system of your instance is configured for UEFI, you need to connect to your instance using RDP.

To determine the boot mode of the instance's operating system

1. [Connect to your Windows instance using RDP \(p. 626\)](#).
2. Go to **System Information** and check the **BIOS Mode** row.

Set the boot mode of an AMI

When you create an AMI using the [register-image](#) command, you can set the boot mode of the AMI to either `uefi`, `legacy-bios`, or `uefi-preferred`.

When the AMI boot mode is set to `uefi-preferred`, the instance boots as follows:

- For instance types that support both UEFI and Legacy BIOS (for example, `m5.large`), the instance boots using UEFI.
- For instance types that support only Legacy BIOS (for example, `m4.large`), the instance boots using Legacy BIOS.

Note

If you set the AMI boot mode to `uefi-preferred`, the operating system must support the ability to boot both UEFI and Legacy BIOS.

Currently, you can't use the [register-image](#) command to create an AMI that supports both [NitroTPM \(p. 1696\)](#) and UEFI Preferred.

Warning

Some features, like UEFI Secure Boot, are only available on instances that boot on UEFI. When you use the `uefi-preferred` AMI boot mode parameter with an instance type that does not support UEFI, the instance will launch as Legacy BIOS and the UEFI-dependent feature will be disabled. If you rely on the availability of a UEFI-dependent feature, set your AMI boot mode parameter to `uefi`.

To convert an existing Legacy BIOS-based instance to UEFI, or an existing UEFI-based instance to Legacy BIOS, you need to perform a number of steps: First, modify the instance's volume and operating system to support the selected boot mode. Then, create a snapshot of the volume. Finally, use [register-image](#) to create the AMI using the snapshot.

You can't set the boot mode of an AMI using the [create-image](#) command. With [create-image](#), the AMI inherits the boot mode of the EC2 instance used for creating the AMI. For example, if you create an AMI from an EC2 instance running on Legacy BIOS, the AMI boot mode will be configured as `legacy-bios`. If you create an AMI from an EC2 instance that was launched using an AMI with a boot mode set to `uefi-preferred`, the AMI that is created will also have its boot mode set to `uefi-preferred`.

Warning

Setting the AMI boot mode parameter does not automatically configure the operating system for the specified boot mode. Before proceeding with these steps, you must first make suitable modifications to the instance's volume and operating system to support booting using the selected boot mode; otherwise, the resulting AMI will not be usable. For example, if you are

converting a Legacy BIOS-based instance to UEFI, you can use the [MBR2GPT](#) tool from Microsoft to convert the system disk from MBR to GPT. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.

To set the boot mode of an AMI (AWS CLI)

1. Make suitable modifications to the instance's volume and operating system to support booting via the selected boot mode. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.

Note

If you don't perform this step, the AMI will not be usable.

2. To find the volume ID of the instance, use the [describe-instances](#) command. You'll create a snapshot of this volume in the next step.

```
aws ec2 describe-instances --region us-east-1 --instance-ids i-1234567890abcdef0
```

Expected output

```
...
    "BlockDeviceMappings": [
        {
            "DeviceName": "/dev/sda1",
            "Ebs": {
                "AttachTime": "",
                "DeleteOnTermination": true,
                "Status": "attached",
                "VolumeId": "vol-1234567890abcdef0"
            }
        }
    ...
}
```

3. To create a snapshot of the volume, use the [create-snapshot](#) command. Use the volume ID from the previous step.

```
aws ec2 create-snapshot --region us-east-1 --volume-id vol-1234567890abcdef0 --description "add text"
```

Expected output

```
{
    "Description": "add text",
    "Encrypted": false,
    "OwnerId": "123",
    "Progress": "",
    "SnapshotId": "snap-01234567890abcdef",
    "StartTime": "",
    "State": "pending",
    "VolumeId": "vol-1234567890abcdef0",
    "VolumeSize": 30,
    "Tags": []
}
```

4. Note the snapshot ID in the output from the previous step.
5. Wait until the snapshot creation is completed before going to the next step. To query the state of the snapshot, use the [describe-snapshots](#) command.

```
aws ec2 describe-snapshots --region us-east-1 --snapshot-ids snap-01234567890abcdef
```

Example output

```
{  
    "Snapshots": [  
        {  
            "Description": "This is my snapshot",  
            "Encrypted": false,  
            "VolumeId": "vol-049df61146c4d7901",  
            "State": "completed",  
            "VolumeSize": 8,  
            "StartTime": "2019-02-28T21:28:32.000Z",  
            "Progress": "100%",  
            "OwnerId": "012345678910",  
            "SnapshotId": "snap-01234567890abcdef",  
            ...  
    ]  
}
```

6. To create a new AMI, use the [register-image](#) command. Use the snapshot ID that you noted in the earlier step.

- To set the boot mode to UEFI, add the --boot-mode parameter to the command and specify uefi as the value.

```
aws ec2 register-image \  
    --region us-east-1 \  
    --description "add description" \  
    --name "add name" \  
    --block-device-mappings "DeviceName=/dev/  
sda1,Ebs={SnapshotId=snap-01234567890abcdef,DeleteOnTermination=true}" \  
    --architecture x86_64 \  
    --root-device-name /dev/sda1 \  
    --virtualization-type hvm \  
    --ena-support \  
    --boot-mode uefi
```

- To set the boot mode to uefi-preferred, add the --boot-mode parameter to the command and specify uefi-preferred as the value.

```
aws ec2 register-image \  
    --region us-east-1 \  
    --description "add description" \  
    --name "add name" \  
    --block-device-mappings "DeviceName=/dev/  
sda1,Ebs={SnapshotId=snap-01234567890abcdef,DeleteOnTermination=true}" \  
    --architecture x86_64 \  
    --root-device-name /dev/sda1 \  
    --virtualization-type hvm \  
    --ena-support \  
    --boot-mode uefi-preferred
```

Expected output

```
{  
    "ImageId": "ami-new_ami_123"  
}
```

7. To verify that the newly-created AMI has the boot mode that you specified in the previous step, use the [describe-images](#) command.

```
aws ec2 describe-images --region us-east-1 --image-id ami-new_ami_123
```

Expected output

```
{  
  "Images": [  
    {  
      "Architecture": "x86_64",  
      "CreationDate": "2021-01-06T14:31:04.000Z",  
      "ImageId": "ami-new_ami_123",  
      "ImageLocation": "",  
      ...  
      "BootMode": "uefi"  
    }  
  ]  
}
```

8. Launch a new instance using the newly-created AMI.

If the AMI boot mode is uefi or legacy-bios, instances created from this AMI will have the same boot mode as the AMI. If the AMI boot mode is uefi-preferred, the instance will boot using UEFI if the instance type supports UEFI; otherwise, the instance will boot using Legacy BIOS. For more information, see [Considerations \(p. 29\)](#).

9. To verify that the new instance has the expected boot mode, use the [describe-instances](#) command.

UEFI variables

When you launch an instance where the boot mode is set to UEFI, a key-value store for variables is created. The store can be used by UEFI and the instance operating system for storing UEFI variables.

UEFI variables are used by the boot loader and the operating system to configure early system startup. They allow the operating system to manage certain settings of the boot process, like the boot order, or managing the keys for UEFI Secure Boot.

Warning

Anyone who can connect to the instance (and potentially any software running on the instance), or anyone with permissions to use the [GetInstanceUefiData](#) API on the instance can read the variables. You should never store sensitive data, such as passwords or personally identifiable information, in the UEFI variable store.

UEFI variable persistence

- For instances that were launched on or before May 10, 2022, UEFI variables are wiped on reboot or stop.
- For instances that are launched on or after May 11, 2022, UEFI variables that are marked as non-volatile are persisted on reboot and stop/start.
- Bare metal instances don't preserve UEFI non-volatile variables across instance stop/start operations.

UEFI Secure Boot

UEFI Secure Boot builds on the long-standing secure boot process of Amazon EC2, and provides additional defense-in-depth that helps customers secure software from threats that persist across reboots. It ensures that the instance only boots software that is signed with cryptographic keys. The

keys are stored in the key database of the [UEFI non-volatile variable store \(p. 38\)](#). UEFI Secure Boot prevents unauthorized modification of the instance boot flow.

Topics

- [How UEFI Secure Boot works \(p. 39\)](#)
- [Launch a Windows instance with UEFI Secure Boot support \(p. 40\)](#)
- [Verify whether a Windows instance is enabled for UEFI Secure Boot \(p. 40\)](#)

How UEFI Secure Boot works

UEFI Secure Boot is a feature specified in UEFI, which provides verification about the state of the boot chain. It is designed to ensure that only cryptographically verified UEFI binaries are executed after the self-initialization of the firmware. These binaries include UEFI drivers and the main bootloader, as well as chain-loaded components.

UEFI Secure Boot specifies four key databases, which are used in a chain of trust. The databases are stored in the UEFI variable store.

The chain of trust is as follows:

Platform key (PK) database

The PK database is the root of trust. It contains a single public PK key that is used in the chain of trust for updating the key exchange key (KEK) database.

To change the PK database, you must have the private PK key to sign an update request. This includes deleting the PK database by writing an empty PK key.

Key exchange key (KEK) database

The KEK database is a list of public KEK keys that are used in the chain of trust for updating the signature (db) and denylist (dbx) databases.

To change the public KEK database, you must have the private PK key to sign an update request.

Signature (db) database

The db database is a list of public keys and hashes that are used in the chain of trust to validate all UEFI boot binaries.

To change the db database, you must have the private PK key or any of the private KEK keys to sign an update request.

Signature denylist (dbx) database

The dbx database is a list of public keys and binary hashes that are not trusted, and are used in the chain of trust as a revocation file.

The dbx database always takes precedence over all other key databases.

To change the dbx database, you must have the private PK key or any of the private KEK keys to sign an update request.

The UEFI Forum maintains a publicly available dbx for many known-bad binaries and certs at <https://uefi.org/revocationlistfile>.

Important

UEFI Secure Boot enforces signature validation on any UEFI binaries. To permit execution of a UEFI binary in UEFI Secure Boot, you sign it with any of the private db keys described above.

By default, UEFI Secure Boot is disabled and the system is in SetupMode. When the system is in SetupMode, all key variables can be updated without a cryptographic signature. When the PK is set, UEFI Secure Boot is enabled and the SetupMode is exited.

Launch a Windows instance with UEFI Secure Boot support

When you [launch an instance \(p. 551\)](#) with the following prerequisites, the instance will automatically validate UEFI boot binaries against its UEFI Secure Boot database. You can also configure UEFI Secure Boot on an instance after launch.

Note

UEFI Secure Boot protects your instance and its operating system against boot flow modifications. Typically, UEFI Secure Boot is configured as part of the AMI. If you create a new AMI with different parameters from the base AMI, such as changing the UefiData within the AMI, you can disable UEFI Secure Boot.

Prerequisites for Windows instances

AMI

Requires an AMI with UEFI Secure Boot enabled.

The following Windows AMIs are preconfigured to enable UEFI Secure Boot with Microsoft keys:

- TPM-Windows_Server-2022-English-Core-Base
- TPM-Windows_Server-2022-English-Full-Base
- TPM-Windows_Server-2022-English-Full-SQL_2022_Enterprise
- TPM-Windows_Server-2022-English-Full-SQL_2022_Standard
- TPM-Windows_Server-2019-English-Core-Base
- TPM-Windows_Server-2019-English-Full-Base
- TPM-Windows_Server-2019-English-Full-SQL_2019_Enterprise
- TPM-Windows_Server-2019-English-Full-SQL_2019_Standard
- TPM-Windows_Server-2016-English-Core-Base
- TPM-Windows_Server-2016-English-Full-Base

Currently, we do not support importing Windows with UEFI Secure Boot by using the [import-image](#) command.

Instance type

- Supported: All virtualized instance types that support UEFI also support UEFI Secure Boot. For the instance types that support UEFI Secure Boot, see [Considerations \(p. 29\)](#).
- Not supported: Bare metal instance types do not support UEFI Secure Boot.

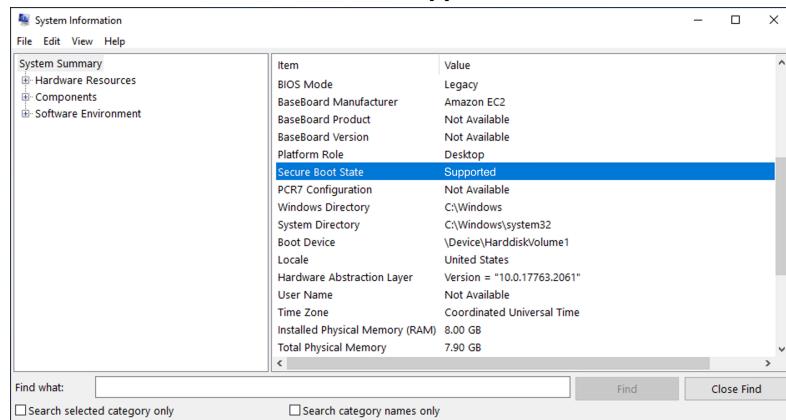

For the prerequisites for Linux instances, see [Launch an instance with UEFI Secure Boot support](#) in the *Amazon EC2 User Guide for Linux Instances*.

Verify whether a Windows instance is enabled for UEFI Secure Boot

To verify whether a Windows instance is enabled for UEFI Secure Boot

1. Open the msinfo32 tool.

2. Check the **Secure Boot State** field. **Supported** indicates that UEFI Secure Boot is enabled.

You can also use the Windows PowerShell Cmdlet `Confirm-SecureBootUEFI` to check the the Secure Boot status. For more information about the cmdlet, see [Confirm-SecureBootUEFI](#) in the *Microsoft Documentation website*.

To verify whether a Linux instance is enabled, see [Verify whether a Linux instance is supported for UEFI Secure Boot](#) in the *Amazon EC2 User Guide for Linux Instances*.

AWS Windows AMIs

AWS provides a set of publicly available AMIs that contain software configurations specific to the Windows platform. You can quickly start building and deploying your applications with Amazon EC2 by using these AMIs. First choose the AMI that meets your specific requirements, and then launch an instance using that AMI. You retrieve the password for the administrator account and then log in to the instance using Remote Desktop Connection, just as you would with any other Windows server.

When you launch an instance from a Windows AMI, the root device for the Windows instance is an Amazon Elastic Block Store (Amazon EBS) volume. Windows AMIs do not support instance store for the root device.

Windows AMIs that have been configured for faster launching are pre-provisioned, using snapshots to launch instances up to 65% faster. To learn more about faster launching for Windows AMIs, including how you can configure faster launching for your Windows AMI, see [Configure your Windows AMI for faster launching \(p. 43\)](#).

Some Windows AMIs include an edition of Microsoft SQL Server (SQL Enterprise Edition, SQL Server Standard, SQL Server Express, or SQL Server Web). Launching an instance from a Windows AMI with Microsoft SQL Server enables you to run the instance as a database server. Alternatively, you can launch an instance from any Windows AMI and then install the database software that you need on the instance.

Note

Microsoft no longer supports Windows Server 2003, 2008, and 2008 R2. We recommend that you launch new EC2 instances using a supported version of Windows Server. If you have existing EC2 instances that are running an unsupported version of Windows Server, we recommend that you upgrade those instances to a supported version of Windows Server. For more information, see [Upgrade an Amazon EC2 Windows instance to a newer version of Windows Server \(p. 927\)](#).

Windows AMI topics

- [Select an initial Windows AMI \(p. 42\)](#)

- [Keep your AMIs up to date \(p. 42\)](#)
- [Virtualization types \(p. 42\)](#)
- [Configure your Windows AMI for faster launching \(p. 43\)](#)
- [Managed AWS Windows AMIs \(p. 55\)](#)
- [Specialized Windows AMIs \(p. 62\)](#)
- [AWS Windows AMI version history \(p. 70\)](#)

Select an initial Windows AMI

To view the Windows AMIs provided by AWS, you can use the Amazon EC2 console or [AWS Marketplace](#). For more information, see [Find a Windows AMI \(p. 123\)](#).

You can also create an AMI from software running on your own Windows computer. For more information, see the following services:

- [AWS Application Migration Service](#)
- [VM Import/Export](#)

Keep your AMIs up to date

AWS provides updated and fully-patched Windows AMIs within five business days of Microsoft's patch Tuesday (the second Tuesday of each month). The AWS Windows AMIs contain the latest security updates available at the time they were created. For more information, see [Details about AWS Windows AMI versions \(p. 56\)](#) and [Patches, security updates, and AMI IDs \(p. 57\)](#).

Use the AWS Systems Manager Automation runbook [AWS-UpdateWindowsAmi](#) to update an AMI by installing Windows updates, Amazon software, and Amazon drivers. You can also use EC2 Image Builder, a fully managed AWS service, to help automate creating up-to-date AMIs. For more information, see the [EC2 Image Builder User Guide](#).

For EC2 instances in an Auto Scaling group, you can create and use the `PatchAMIAndUpdateASG` runbook to update an Auto Scaling group with a newly patched AMI. For more information, see [Updating AMIs for Auto Scaling groups](#) in the *AWS Systems Manager User Guide*.

For existing EC2 instances, we recommend that you regularly patch, update, and secure the operating system and applications. For more information, see [Update your Windows instance \(p. 60\)](#).

Virtualization types

AMIs use one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). The main differences between PV and HVM AMIs are the way in which they boot and whether they can take advantage of special hardware extensions for better performance. Windows AMIs are HVM AMIs.

HVM AMIs are presented with a fully virtualized set of hardware and boot by executing the master boot record of the root block device of your image. This virtualization type provides the ability to run an operating system directly on top of a virtual machine without any modification, as if it were run on the bare-metal hardware. The Amazon EC2 host system emulates some or all of the underlying hardware that is presented to the guest.

HVM guests can take advantage of hardware extensions that provide fast access to the underlying hardware on the host system. HVM AMIs are required to take advantage of enhanced networking and

GPU processing. In order to pass through instructions to specialized network and GPU devices, the OS needs to be able to have access to the native hardware platform; HVM virtualization provides this access.

Paravirtual guests traditionally performed better with storage and network operations than HVM guests because they could leverage special drivers for I/O that avoided the overhead of emulating network and disk hardware, whereas HVM guests had to translate these instructions to emulated hardware. Now PV drivers are available for HVM guests, so Windows instances can get performance advantages in storage and network I/O by using them. With these PV on HVM drivers, HVM guests can get the same performance as paravirtual guests, or better.

Configure your Windows AMI for faster launching

Every EC2 Windows instance must go through the standard Windows operating system (OS) launch steps, which include several reboots, and often take 15 minutes or longer to complete. Windows AMIs that are optimized for faster launching complete some of those steps and reboots in advance by launching a set of instances in the background, and then creating snapshots when they have completed the initial launch steps. The use of these snapshots in the faster launching process can significantly reduce the time it takes to launch instances when they are needed.

When you configure a Windows AMI for faster launching, Amazon EC2 automatically creates the snapshots for you, based on your settings, and you only pay for the resources that the process consumes. This is not the same process as [EBS fast snapshot restore](#). EBS fast snapshot restore must be explicitly enabled on a per-snapshot basis, and has its own associated costs.

Note

Any account that has access to an AMI with faster launching enabled can benefit from reduced launch times. However, it is the AMI owner's account that provides the snapshots that are consumed for the launch.

Key terms

- **Pre-provisioned snapshot** – A snapshot of an instance that was launched from a Windows AMI with faster launching enabled, and that has completed the following Windows launch steps, rebooting as required. Amazon EC2 creates these snapshots automatically, based on your configuration.
 - Sysprep specialize
 - Windows Out of Box Experience (OOBE)

When these steps are complete, Amazon EC2 stops the instance, and creates a snapshot that is later used for faster launching from the AMI.

- **Launch frequency** – Controls the number of pre-provisioned snapshots that Amazon EC2 can launch within the specified timeframe. When you enable Windows Fast Launch for your AMI, Amazon EC2 creates the initial set of pre-provisioned snapshots in the background. For example, if the launch frequency is set to five launches per hour, which is the default, then Amazon EC2 creates an initial set of five pre-provisioned snapshots.

When Amazon EC2 launches an instance from an AMI with Windows Fast Launch enabled, it uses one of the pre-provisioned snapshots to reduce the launch time. As snapshots are used, they are automatically replenished, up to the number specified by the launch frequency.

If you expect a spike in the number of instances that are launched from your AMI – during a special event, for example – you can increase the launch frequency in advance to cover the additional instances that you'll need. When your launch rate returns to normal, you can adjust the frequency back down.

When you experience a higher number of launches than anticipated, you might use up all the faster launching snapshots that you have available. This does not cause any launches to fail. However, it can result in some instances going through the standard launch process, until snapshots can be replenished.

- **Target resource count** – The number of pre-provisioned snapshots to keep on hand for an AMI with Windows Fast Launch enabled.
- **Max parallel launches** – Controls how many instances can be launched at a time for creating the pre-provisioned snapshots. If your target resource count is higher than the maximum number of parallel launches you've configured, Amazon EC2 will initially launch the number of instances specified by the **Max parallel launches** setting for creating the snapshots. As those instances complete the process and Amazon EC2 takes the snapshot and stops the instance, more instances are launched until the total number of snapshots available has reached the target resource count. This value must be 6 or greater.

Resource costs

There is no service charge to configure Windows AMIs for faster launching. However, standard pricing applies for underlying AWS resources that are used to prepare and store the pre-provisioned snapshots. The following example demonstrates how associated costs are allocated.

Example scenario: The AtoZ Example company has a Windows AMI with a 50 GiB EBS root volume. They enable faster launching for their AMI, and set the target resource count to five. Over the course of a month, using Windows faster launching for their AMI costs them around \$5.00, and the cost breakdown is as follows:

1. When AtoZ Example enables faster launching, Amazon EC2 launches five small instances. Each instance runs through the Sysprep and OOBE Windows launch steps, rebooting as required. This takes several minutes for each instance (time can vary, based on how busy that Region or Availability Zone (AZ) is, and on the size of the AMI).

Costs

- Instance runtime costs (or minimum runtime, if applicable): five instances
- Volume costs: five EBS root volumes

2. When the pre-provisioning process completes, Amazon EC2 takes a snapshot of the instance, which it stores in Amazon S3. Snapshots are typically stored for 4–8 hours before they are consumed by a launch. In this case, the cost is roughly \$0.02 to \$0.05 per snapshot.

Costs

- Snapshot storage (Amazon S3): five snapshots
3. After Amazon EC2 takes the snapshot, it stops the instance. At that point, the instance is no longer accruing costs. However EBS volume costs continue to accrue.

Costs

- EBS volumes: costs continue for the associated EBS root volumes.

Note

The costs shown here are for demonstration purposes only. Your costs will vary, depending on your AMI configuration and pricing plan.

Track faster launching costs on your bill

Cost allocation tags can help you organize your AWS bill to reflect the costs associated with Windows Fast Launch. You can use the following tag that Amazon EC2 adds to the resources it creates when it prepares and stores pre-provisioned snapshots for Windows Fast Launch:

Tag key: CreatedBy, **Value:** EC2 Fast Launch

After you activate the tag in the Billing and Cost Management console, and set up your detailed billing report, the `user:CreatedBy` column appears on the report. The column includes values from all

services. However, if you download the CSV file, you can import the data into a spreadsheet, and filter for EC2 Fast Launch in the value. This information also appears in the AWS Cost and Usage Report when the tag is activated.

Step 1: Activate user-defined cost allocation tags

To include resource tags in your cost reports, you must first activate the tag in the Billing and Cost Management console. For more information, see [Activating User-Defined Cost Allocation Tags](#) in the *AWS Billing and Cost Management User Guide*.

Note

Activation can take up to 24 hours.

Step 2: Set up a cost report

If you already have a cost report set up, a column for your tag appears the next time the report runs after activation is complete. To set up cost reports for the first time, choose one of the following.

- See [Setting up a monthly cost allocation report](#) in the *AWS Billing and Cost Management User Guide*.
- See [Creating Cost and Usage Reports](#) in the *AWS Cost and Usage Report User Guide*.

Note

It can take up to 24 hours for AWS to start delivering reports to your S3 bucket.

You can configure Windows AMIs that you own for faster launching using the Amazon EC2 console, API, SDKs, or `ec2` commands in the AWS CLI. The following sections cover configuration steps for the Amazon EC2 console and AWS CLI.

Contents

- [Prerequisites \(p. 45\)](#)
- [Use a launch template when you set up Windows Fast Launch \(p. 46\)](#)
- [Start Windows Fast Launch \(p. 47\)](#)
- [Stop Windows Fast Launch \(p. 49\)](#)
- [View AMIs with Windows Fast Launch enabled \(AWS CLI\) \(p. 50\)](#)
- [Monitor state changes with EventBridge \(p. 52\)](#)
- [Service-linked role for Windows Fast Launch \(p. 54\)](#)

Prerequisites

Before you set up Windows Fast Launch, verify that you've met the following prerequisites:

- If you don't use a launch template to configure your settings, ensure that a default VPC is configured for the Region in which you use Windows Fast Launch.

Note

If you accidentally delete your default VPC in the Region where you plan to configure Windows Fast Launch, you can create a new default VPC in that Region. To learn more, see [Create a default VPC](#) in the *Amazon VPC User Guide*.

- To specify a non-default VPC, you must use a launch template when you configure Windows fast launch. For more information, see [Use a launch template when you set up Windows Fast Launch \(p. 46\)](#).
- If your account includes a policy that enforces IMDSv2 for Amazon EC2 instances, you must create a launch template that specifies the metadata configuration to enforce IMDSv2.
- To change the settings for Windows Fast Launch, your AWS account must own the Windows AMI.

- To configure Windows Fast Launch for an AMI, you must create the AMI using **Sysprep** with the shutdown option. EC2 Windows Fast Launch doesn't currently support AMIs that were created from a running instance. To create an AMI using **Sysprep**, see [Create a custom Windows AMI \(p. 151\)](#).

Use a launch template when you set up Windows Fast Launch

With a launch template, you can configure a set of launch parameters that Amazon EC2 uses each time it launches an instance from that template. You can specify such things as an AMI to use for your base image, instance types, storage, network settings, and more.

Launch templates are optional, except for the following specific cases, where you must use a launch template for your Windows AMI when you configure faster launching:

- You must use a launch template to specify a non-default VPC for your Windows AMI.
- If your account includes a policy that enforces IMDSv2 for Amazon EC2 instances, you must create a launch template that specifies the metadata configuration to enforce IMDSv2.

Use the launch template that includes your metadata configuration from the EC2 console, or when you run the [enable-fast-launch](#) command in the AWS CLI, or call the [EnableFastLaunch](#) API action.

Note

Amazon EC2 Windows Fast Launch doesn't support user data scripts in the launch template. If you use a launch template for Windows Fast Launch, you must not specify user data.

Specify a non-default VPC

Step 1: Create a launch template

Create a launch template that specifies the VPC for your Windows instances from the AWS Management Console or from the AWS CLI. For more information, see [Create a launch template \(p. 570\)](#).

Step 2: Specify the launch template for your Windows Fast Launch AMI

- To specify the launch template for Windows Fast Launch, follow these steps:
 1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
 2. In the navigation pane, under **Images**, choose **AMIs**.
 3. Choose the AMI to update by selecting the check box next to the **Name**.
 4. From the **Actions** menu above the list of AMIs, choose **Manage image optimization**. This opens the **Manage image optimization** page, where you configure the settings for Windows Fast Launch.
 5. The **Launch template** box performs a filtered search that finds launch templates in your account in the current Region that match the text you've entered. Specify all or part of the launch template name or ID in the box to show a list of matching launch templates. For example, if you enter fast in the box, Amazon EC2 finds all of the launch templates in your account in the current Region that have "fast" in the name.

To create a new launch template, you can choose **Create launch template**.

- 6. When you select a launch template, Amazon EC2 shows the default version for that template in the **Source template version** box. To specify a different version, highlight the default version to replace it, and enter the version number you want in the box.
- 7. When you're done making changes, choose **Save changes**.
- Specify the launch template name or ID in the --launch-template parameter when you run the [enable-fast-launch](#) command in the AWS CLI.

- Specify the launch template name or ID in the LaunchTemplate parameter when you call the [EnableFastLaunch](#) API action.

For more information about EC2 launch templates, see [Launch an instance from a launch template \(p. 567\)](#).

Start Windows Fast Launch

To start Windows Fast Launch, choose the tab that matches your environment, and follow the steps.

Note

Before changing these settings, make sure that your AMI, and the Region that you run in meet all [Prerequisites \(p. 45\)](#).

Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, under **Images**, choose **AMIs**.
3. Choose the AMI to update by selecting the check box next to the **Name**.
4. From the **Actions** menu above the list of AMIs, choose **Manage image optimization**. This opens the **Manage image optimization** page, where you configure the settings for Windows Fast Launch.
5. To start using pre-provisioned snapshots to launch instances from your Windows AMI faster, select the **Enable Windows faster launching** check box.
6. From the **Set anticipated launch frequency** drop-down list, choose a value to specify the number of snapshots that are created and maintained to cover your expected instance launch volume.
7. When you're done making changes, choose **Save changes**.

Note

If you need to use a launch template to specify a non-default VPC, or to configure metadata settings for IMDSv2, see [Use a launch template when you set up Windows Fast Launch \(p. 46\)](#).

AWS CLI

The **enable-fast-launch** command calls the Amazon EC2 [EnableFastLaunch](#) API operation.

Syntax:

```
aws ec2 enable-fast-launch \
--image-id <value> \
--resource-type <value> \ (optional)
--snapshot-configuration <value> \ (optional)
--launch-template <value> \ (optional)
--max-parallel-launches <value> \ (optional)
--dry-run | --no-dry-run \ (optional)
--cli-input-json <value> \ (optional)
--generate-cli-skeleton <value> \ (optional)
```

Example:

The following [enable-fast-launch](#) example starts Windows Fast Launch for the specified AMI, launching six parallel instances for pre-provisioning. The ResourceType is set to snapshot, which is the default value.

```
aws ec2 enable-fast-launch \
--image-id ami-01234567890abcdef \
```

```
--max-parallel-launches 6 \
--resource-type snapshot
```

Output:

```
{  
    "ImageId": "ami-01234567890abcdef",  
    "ResourceType": "snapshot",  
    "SnapshotConfiguration": {  
        "TargetResourceCount": 10  
    },  
    "LaunchTemplate": {},  
    "MaxParallelLaunches": 6,  
    "OwnerId": "0123456789123",  
    "State": "enabling",  
    "StateTransitionReason": "Client.UserInitiated",  
    "StateTransitionTime": "2022-01-27T22:16:03.199000+00:00"  
}
```

Tools for Windows PowerShell

The **Enable-EC2FastLaunch** cmdlet calls the Amazon EC2 [EnableFastLaunch](#) API operation.

Syntax:

```
Enable-EC2FastLaunch  
    -ImageId <String>  
    -LaunchTemplate_LaunchTemplateId <String>  
    -LaunchTemplate_LaunchTemplateName <String>  
    -MaxParallelLaunch <Int32>  
    -ResourceType <String>  
    -SnapshotConfiguration_TargetResourceCount <Int32>  
    -LaunchTemplate_Version <String>  
    -Select <String>  
    -PassThru <SwitchParameter>  
    -Force <SwitchParameter>
```

Example:

The following [Enable-EC2FastLaunch](#) example starts Windows Fast Launch for the specified AMI, launching six parallel instances for pre-provisioning. The ResourceType is set to snapshot, which is the default value.

```
Enable-EC2FastLaunch `'  
-ImageId ami-01234567890abcdef`'  
-MaxParallelLaunch 6`'  
-Region us-west-2`'  
-ResourceType snapshot
```

Output:

```
ImageId      : ami-01234567890abcdef  
LaunchTemplate :  
MaxParallelLaunches : 6  
OwnerId       : 0123456789123  
ResourceType   : snapshot  
SnapshotConfiguration : Amazon.EC2.Model.FastLaunchSnapshotConfigurationResponse  
State         : enabling  
StateTransitionReason : Client.UserInitiated  
StateTransitionTime  : 2/25/2022 12:24:11 PM
```

Stop Windows Fast Launch

To stop Windows Fast Launch, choose the tab that matches your environment, and follow the steps.

Note

Before changing these settings, make sure that your AMI, and the Region that you run in meet all [Prerequisites \(p. 45\)](#).

Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, under **Images**, choose **AMIs**.
3. Choose the AMI to update by selecting the check box next to the **Name**.
4. From the **Actions** menu above the list of AMIs, choose **Manage image optimization**. This opens the **Manage image optimization** page, where you configure the settings for Windows Fast Launch.
5. Clear the **Enable Windows faster launching** check box to stop Windows Fast Launch and to remove pre-provisioned snapshots. This results in the AMI using the standard launch process for each instance, going forward.

Note

When you stop Windows image optimization, any existing pre-provisioned snapshots are automatically deleted. This step must be completed before you can start using the feature again.

6. When you're done making changes, choose **Save changes**.

AWS CLI

The **disable-fast-launch** command calls the Amazon EC2 [DisableFastLaunch](#) API operation.

Syntax:

```
aws ec2 disable-fast-launch \
--image-id <value> \
--force | --no-force \ (optional)
--dry-run | --no-dry-run \ (optional)
--cli-input-json <value> \ (optional)
--generate-cli-skeleton <value> \ (optional)
```

Example:

The following [disable-fast-launch](#) example stops Windows Fast Launch on the specified AMI, and cleans up existing pre-provisioned snapshots.

```
aws ec2 disable-fast-launch \
--image-id ami-01234567890abcdef
```

Output:

```
{
    "ImageId": "ami-01234567890abcdef",
    "ResourceType": "snapshot",
    "SnapshotConfiguration": {},
    "LaunchTemplate": {
        "LaunchTemplateId": "lt-01234567890abcdef",
        "LaunchTemplateName": "EC2FastLaunchDefaultResourceCreation-
a8c6215d-94e6-441b-9272-dbd1f87b07e2",
        "Version": "1"
    }
}
```

```
},  
"MaxParallelLaunches": 6,  
"OwnerId": "0123456789123",  
"State": "disabling",  
"StateTransitionReason": "Client.UserInitiated",  
"StateTransitionTime": "2022-01-27T22:47:29.265000+00:00"  
}
```

Tools for Windows PowerShell

The **Disable-EC2FastLaunch** cmdlet calls the Amazon EC2 [DisableFastLaunch](#) API operation.

Syntax:

```
Disable-EC2FastLaunch  
-ImageId <String>  
-ForceStop <Boolean>  
-Select <String>  
-PassThru <SwitchParameter>  
-Force <SwitchParameter>
```

Example:

The following [Disable-EC2FastLaunch](#) example stops Windows Fast Launch on the specified AMI, and cleans up existing pre-provisioned snapshots.

```
Disable-EC2FastLaunch -ImageId ami-01234567890abcdef
```

Output:

```
ImageId          : ami-01234567890abcdef  
LaunchTemplate   : Amazon.EC2.Model.FastLaunchLaunchTemplateSpecificationResponse  
MaxParallelLaunches : 6  
OwnerId         : 0123456789123  
ResourceType    : snapshot  
SnapshotConfiguration :  
State           : disabling  
StateTransitionReason : Client.UserInitiated  
StateTransitionTime : 2/25/2022 1:10:08 PM
```

View AMIs with Windows Fast Launch enabled (AWS CLI)

You can use the [describe-fast-launch-images](#) command in the AWS CLI, or the [Get-EC2FastLaunchImage](#) Tools for Windows PowerShell cmdlet to get details for AMIs that have Windows Fast Launch enabled.

Amazon EC2 provides the following details for each Windows AMI that is returned in the results:

- The image ID for an AMI with Windows Fast Launch enabled.
- The resource type that is used for pre-provisioning the associated Windows AMI. Supported value: `snapshot`.
- The snapshot configuration, which is a group of parameters that configure pre-provisioning for the associated Windows AMI using snapshots.
- Launch template information, including the ID, name, and version of the launch template that the associated AMI uses when it launches Window instances from pre-provisioned snapshots.
- The maximum number of instances that can be launched at the same time for creating resources.
- The owner ID for the associated AMI.

- The current state of Windows Fast Launch for the associated AMI. Supported values include: enabling | enabling-failed | enabled | enabled-failed | disabling | disabling-failed.

Note

You can also see the current state displayed in the **Manage image optimization** page in the EC2 console, as **Image optimization state**.

- The reason that Windows Fast Launch for the associated AMI changed to the current state.
- The time that Windows Fast Launch for the associated AMI changed to the current state.

Choose the tab that matches your command line environment:

AWS CLI

The **describe-fast-launch-images** command calls the Amazon EC2 [DescribeFastLaunchImages](#) API operation.

Syntax:

```
aws ec2 describe-fast-launch-images \
--image-ids <value> \ (optional)
--filters <value> \ (optional)
--dry-run | --no-dry-run \ (optional)
--cli-input-json <value> \ (optional)
--starting-token <value> \ (optional)
--page-size <value> \ (optional)
--max-items <value> \ (optional)
--generate-cli-skeleton <value> \ (optional)
```

Example:

The following [describe-fast-launch-images](#) example describes the details for each of the AMIs in the account that are configured for Windows Fast Launch. In this example, only one AMI in the account is configured for Windows Fast Launch.

```
aws ec2 describe-fast-launch-images
```

Output:

```
{
    "FastLaunchImages": [
        {
            "ImageId": "ami-01234567890abcdef",
            "ResourceType": "snapshot",
            "SnapshotConfiguration": {},
            "LaunchTemplate": {
                "LaunchTemplateId": "lt-01234567890abcdef",
                "LaunchTemplateName": "EC2FastLaunchDefaultResourceCreation-
a8c6215d-94e6-441b-9272-dbd1f87b07e2",
                "Version": "1"
            },
            "MaxParallelLaunches": 6,
            "OwnerId": "0123456789123",
            "State": "enabled",
            "StateTransitionReason": "Client.UserInitiated",
            "StateTransitionTime": "2022-01-27T22:20:06.552000+00:00"
        }
    ]
}
```

Tools for Windows PowerShell

The **Get-EC2FastLaunchImage** cmdlet calls the Amazon EC2 [DescribeFastLaunchImages API](#) operation.

Syntax:

```
Get-EC2FastLaunchImage
-Filter <Filter[]>
-ImageId <String[]>
-MaxResult <Int32>
-NextToken <String>
-Select <String>
-NoAutoIteration <SwitchParameter>
```

Example:

The following [Get-EC2FastLaunchImage](#) example describes the details for each of the AMIs in the account that are configured for Windows Fast Launch. In this example, only one AMI in the account is configured for Windows Fast Launch.

```
Get-EC2FastLaunchImage -ImageId ami-01234567890abcdef
```

Output:

```
ImageId      : ami-01234567890abcdef
LaunchTemplate : Amazon.EC2.Model.FastLaunchLaunchTemplateSpecificationResponse
MaxParallelLaunches : 6
OwnerId      : 0123456789123
ResourceType   : snapshot
SnapshotConfiguration :
State         : enabled
StateTransitionReason : Client.UserInitiated
StateTransitionTime  : 2/25/2022 12:54:43 PM
```

Monitor state changes with EventBridge

When the state changes for a Windows AMI with Windows Fast Launch enabled, Amazon EC2 generates an EC2 Fast Launch State-change Notification event. Then Amazon EC2 sends the state change event to Amazon EventBridge (formerly known as Amazon CloudWatch Events).

You can create EventBridge rules that trigger one or more actions in response to the state change event. For example, you can create an EventBridge rule that detects when Windows Fast Launch is enabled and performs the following actions:

- Sends a message to an Amazon SNS topic that notifies its subscribers.
- Invokes a Lambda function that performs some action.
- Sends the state change data to Amazon Kinesis Data Firehose for analytics.

For more information, see [Creating Amazon EventBridge rules that react to events](#) in the *Amazon EventBridge User Guide*.

State change events

The Windows Fast Launch feature emits JSON formatted state change events on a best-effort basis. Amazon EC2 sends the events to EventBridge in near real time. This section describes the event fields and shows an example of the event format.

EC2 Fast Launch State-change Notification

imageId

Identifies the AMI with the Windows Fast Launch state change.

resourceType

The type of resource to use for pre-provisioning. Supported value: `snapshot`. The default value is `snapshot`.

state

The current state of the Windows Fast Launch feature for the specified AMI. Valid values include the following:

- **enabling** – You've enabled the Windows Fast Launch feature for the AMI, and Amazon EC2 has started creating snapshots for the pre-provisioning process.
- **enabling-failed** – Something went wrong that caused the pre-provisioning process to fail the first time that you enabled the Windows Fast Launch for an AMI. This can happen anytime during the pre-provisioning process.
- **enabled** – The Windows Fast Launch feature is enabled. The state changes to enabled as soon as Amazon EC2 creates the first pre-provisioned snapshot for a newly enabled Windows Fast Launch AMI. If the AMI was already enabled and goes through pre-provisioning again, the state change happens right away.
- **enabled-failed** – This state applies only if this is not the first time your Windows Fast Launch AMI goes through the pre-provisioning process. This can happen if the Windows Fast Launch feature is disabled and then later enabled again, or if there is a configuration change or other error after pre-provisioning is completed for the first time.
- **disabling** – The AMI owner has turned off the Windows Fast Launch feature for the AMI, and Amazon EC2 has started the clean up process.
- **disabled** – The Windows Fast Launch feature is disabled. The state changes to disabled as soon as Amazon EC2 completes the clean up process.
- **disabling-failed** – Something went wrong that caused the clean up process to fail. This means that some pre-provisioned snapshots may still remain in the account.

stateTransitionReason

The reason that the state changed for the Windows Fast Launch AMI.

Note

All fields in this event message are required.

The following example shows a newly enabled Windows Fast Launch AMI that has launched the first instance to start the pre-provisioning process. At this point, the state is `enabling`. After Amazon EC2 creates the first pre-provisioned snapshot, the state changes to `enabled`.

```
{  
  "version": "0",  
  "id": "01234567-0123-0123-0123-012345678901",  
  "detail-type": "EC2 Fast Launch State-change Notification",  
  "source": "aws.ec2",  
  "account": "123456789012",  
  "time": "2022-08-31T20:30:12Z",  
  "region": "us-east-1",  
  "resources": [  
    "arn:aws:ec2:us-east-1:123456789012:image/ami-123456789012"  
  ],  
  "detail": {  
    "imageId": "ami-123456789012",  
    "resourceType": "snapshot",  
  }  
}
```

```
        "state": "enabling",
        "stateTransitionReason": "Client.UserInitiated"
    }
}
```

Service-linked role for Windows Fast Launch

Amazon EC2 uses service-linked roles for the permissions that it requires to call other AWS services on your behalf. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles provide a secure way to delegate permissions to AWS services because only the linked service can assume a service-linked role. For more information about how Amazon EC2 uses IAM roles, including service-linked roles, see [IAM roles for Amazon EC2 \(p. 1649\)](#).

Amazon EC2 uses the service-linked role named `AWSServiceRoleForEC2FastLaunch` to create and manage a set of pre-provisioned snapshots that reduce the time it takes to launch instances from your Windows AMI.

You don't need to create this service-linked role manually. When you start using Windows Fast Launch for your AMI, Amazon EC2 creates the service-linked role for you, if it doesn't already exist.

Note

If the service-linked role is deleted from your account, you can start Windows Fast Launch for another Windows AMI to re-create the role in your account. Alternatively, you can stop Windows Fast Launch for your current AMI, and then start it again. However, stopping the feature results in your AMI using the standard launch process for all new instances while Amazon EC2 removes all of your pre-provisioned snapshots. After all of the pre-provisioned snapshots are gone, you can start using Windows Fast Launch for your AMI again.

Amazon EC2 does not allow you to edit the `AWSServiceRoleForEC2FastLaunch` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role by using IAM. For more information, see [Editing a Service-Linked Role](#) in the *IAM User Guide*.

You can delete a service-linked role only after first deleting all of the related resources. This protects the Amazon EC2 resources that are associated with your AMI with Windows Fast Launch enabled, because you can't inadvertently remove permission to access the resources.

Amazon EC2 supports the Windows Fast Launch service-linked role in all of the Regions where the Amazon EC2 service is available. For more information, see [Regions \(p. 1222\)](#).

Permissions granted by `AWSServiceRoleForEC2FastLaunch`

Amazon EC2 uses the `EC2FastLaunchServiceRolePolicy` managed policy to complete the following actions:

- `cloudwatch:PutMetricData` – Post metric data associated with Windows Fast Launch to the Amazon EC2 namespace.
- `ec2:CreateLaunchTemplate` – Create a launch template for your AMI with Windows Fast Launch enabled.
- `ec2:CreateSnapshot` – Create pre-provisioned snapshots for your AMI with Windows Fast Launch enabled.
- `ec2:CreateTags` – Create tags for resources that are associated with launching and pre-provisioning Windows instances for your AMI with Windows Fast Launch enabled.
- `ec2:DeleteSnapshots` – Delete all associated pre-provisioned snapshots if Windows Fast Launch is turned off for a previously enabled AMI.
- `ec2:DescribeImages` – Describe images for all resources.
- `ec2:DescribeInstanceAttribute` – Describe instance attributes for all resources.
- `ec2:DescribeInstanceStatus` – Describe instance status for all resources.

- `ec2:DescribeInstances` – Describe instances for all resources.
- `ec2:DescribeInstanceTypeOfferings` – Describe instance type offerings for all resources.
- `ec2:DescribeLaunchTemplates` – Describe launch templates for all resources.
- `ec2:DescribeLaunchTemplateVersions` – Describe launch template versions for all resources.
- `ec2:DescribeSnapshots` – Describe snapshot resources for all resources.
- `ec2:DescribeSubnets` – Describe subnets for all resources.
- `ec2:RunInstances` – Launch instances from an AMI with Windows Fast Launch enabled, in order to perform provisioning steps.
- `ec2:StopInstances` – Stop instances that were launched from an AMI with Windows Fast Launch enabled, in order to create pre-provisioned snapshots.
- `ec2:TerminateInstances` – Terminate an instance that was launched from an AMI with Windows Fast Launch enabled, after creating the pre-provisioned snapshot from it.
- `iam:PassRole` – Allows the `AWSServiceRoleForEC2FastLaunch` service-linked role to launch instances on your behalf using the instance profile from your launch template.

For more information about using managed policies for Amazon EC2, see [AWS managed policies for Amazon Elastic Compute Cloud \(p. 1647\)](#).

Access to customer managed keys for use with encrypted AMIs and EBS snapshots

Prerequisite

- To enable Amazon EC2 to access an encrypted AMI on your behalf, you must have permission for the `createGrant` action in the customer managed key.

When you enable Windows Fast Launch for an encrypted AMI, Amazon EC2 ensures that permission is granted for the `AWSServiceRoleForEC2FastLaunch` role to use the customer managed key to access your AMI. This permission is needed to launch instances and create pre-provisioned snapshots on your behalf.

Managed AWS Windows AMIs

AWS provides managed Amazon Machine Images (AMIs) that include various versions and configurations of Windows Server. In general, the AWS Windows AMIs are configured with the default settings used by the Microsoft installation media. However, there are customizations. For example, the AWS Windows AMIs come with the following software and drivers:

- EC2Launch v2 (Windows Server 2022)
- EC2Launch (Windows Server 2016 and 2019)
- EC2Config service (through Windows Server 2012 R2)
- AWS Systems Manager
- AWS CloudFormation
- AWS Tools for Windows PowerShell
- Network drivers (SRIOV, ENA, Citrix PV)
- Storage drivers (NVMe, AWS PV, Citrix PV)
- Graphics drivers (Nvidia GPU, Elastic GPU)
- Spot Instance hibernation

For information about other customizations, see [AWS Windows AMIs \(p. 41\)](#).

Managed Windows AMIs topics

Details about AWS Windows AMI versions

Where AWS gets the Windows Server installation media

When a new version of Windows Server is released, we download the Windows ISO from Microsoft and validate the hash Microsoft publishes. An initial AMI is then created from the Windows distribution ISO. The drivers needed to boot on EC2 are included in addition to our EC2 launch agent. To prepare this initial AMI for public release, we perform automated processes to convert the ISO to an AMI. This prepared AMI is used for the monthly automated update and release process.

What to expect in an official AWS Windows AMI

AWS provides AMIs with a variety of configurations for popular versions of Microsoft supported Windows Server Operating Systems. As outlined in the previous section, we start with the Windows Server ISO from Microsoft's Volume Licensing Service Center (VLSC) and validates the hash to ensure it matches Microsoft's documentation for new Windows Server operating systems.

We perform the following changes using automation on AWS to take the current Windows Server AMIs and update them:

- Install all Microsoft recommended Windows security patches. We release images shortly after the monthly Microsoft patches are made available.
- Install the latest drivers for AWS hardware, including network and disk drivers, EC2WinUtil for troubleshooting, as well as GPU drivers in selected AMIs.
- Include the following AWS launch agent software by default:
 - [EC2Launch v2 \(p. 692\)](#) for Windows Server 2022 and optionally for Windows Server 2019 and 2016 with specific AMIs. For more information, see [Configure a Windows instance using EC2Launch v2](#).
 - [EC2Launch \(p. 743\)](#) for Windows Server 2016 and 2019.
 - [EC2Config \(p. 753\)](#) for Windows Server 2012 R2 and earlier.
- Configure Windows Time to use the [Amazon Time Sync Service \(p. 839\)](#).
- Make changes in all power schemes to set the display to never turn off.
- Perform minor bug fixes – generally one-line registry changes to enable or disable features that we have found to improve performance on AWS.
- Tests and validates AMIs across new and existing EC2 platforms to ensure compatibility, stability, and consistency prior to release.
- Other than the previously mentioned changes, we keep the AMIs as close as possible to the Microsoft default installation of Windows Server. For example, we keep the PowerShell and .NET Framework installations as they are and don't install additional Windows roles, role services, or features.

How AWS validates security, integrity, and authenticity of software on AMIs

We take a number of steps during the image build process, to maintain the security, integrity, and authenticity of AWS provided Windows AMIs. A few examples include:

- AWS provided Windows AMIs are built using source media obtained directly from Microsoft.
- Windows Updates are downloaded directly from Microsoft's Windows Update Service by Windows, and installed on the instance used to create the AMI during the image build process.
- AWS Software is downloaded from secure S3 buckets and installed in the AMIs.
- Drivers—such as for the chipset and GPU—are obtained directly from the vendor, stored in secure S3 buckets, and installed on the AMIs during the image build process.

How AWS decides which Windows AMIs to offer

Each AMI is extensively tested prior to release to the general public. We periodically streamline our AMI offerings to simplify customer choice and to reduce costs.

- New AMI offerings are created for new OS releases. You can count on AWS releasing "Base," "Core/Container," and "SQL Express/Standard/Web/Enterprise" offerings in English and other widely used languages. The primary difference between Base and Core offerings is that Base offerings have a desktop/GUI whereas Core offerings are PowerShell command line only. For more information about Windows Server Core, see <https://docs.microsoft.com/en-us/windows-server/administration/server-core/what-is-server-core>.
- New AMI offerings are created to support new platforms – for example, the Deep Learning and "NVIDIA" AMIs were created to support customers using our GPU-based instance types (P2 and P3, G2 and G3, and more).
- Less popular AMIs are sometimes removed. If we see a particular AMI is launched only a few times in its entire lifespan, we will remove it in favor of more widely used options.

If there is an AMI variant that you would like to see, let us know by filing a ticket with Cloud Support, or by providing feedback through [one of our established channels](#).

Patches, security updates, and AMI IDs

AWS provides updated, fully-patched Windows AMIs within five business days of Microsoft's patch Tuesday (the second Tuesday of each month). The new AMIs are available immediately from the **Images** page in the Amazon EC2 console. The new AMIs are available in the AWS Marketplace and the **Quick Start** tab of the launch instance wizard within a few days of their release.

Note

Instances launched from Windows Server 2019 and later AMIs may show a Windows Update dialog message stating "Some settings are managed by your organization." This message appears as a result of changes in Windows Server 2019 and does not impact the behavior of Windows Update or your ability to manage update settings.

To remove this warning, see ["Some settings are managed by your organization"](#).

To ensure that customers have the latest security updates by default, AWS keeps Windows AMIs available for three months. After releasing new Windows AMIs, AWS makes the Windows AMIs that are older than three months private within 10 days. After an AMI has been made private, when you look at an instance launched from that AMI in the console, the **AMI ID** field states, "Cannot load detail for ami-xxxxx. You may not be permitted to view it." You can still retrieve the AMI ID using the AWS CLI or an AWS SDK.

The Windows AMIs in each release have new AMI IDs. Therefore, we recommend that you write scripts that locate the latest AWS Windows AMIs by their names, rather than by their IDs. For more information, see the following examples:

- [Get-EC2ImageByName](#) (AWS Tools for Windows PowerShell)

- [Query for the Latest Windows AMI Using Systems Manager Parameter Store](#)
- [Walkthrough: Looking Up Amazon Machine Image IDs \(AWS Lambda, AWS CloudFormation\)](#)

Configuration changes for AWS Windows AMIs

The following configuration changes are applied to each AWS Windows AMI.

Clean and prepare

Change	Applies to
Check for pending file renames or reboots, and reboot as needed	All AMIs
Delete .dmp files	All AMIs
Delete logs (event logs, Systems Manager, EC2Config)	All AMIs
Delete temporary folders and files for Sysprep	All AMIs
Clear recent history (Start menu, Windows Explorer, and more)	Windows Server 2012 R2 and earlier
Perform virus scan	All AMIs
Pre-compile queued .NET assemblies (before Sysprep)	All AMIs
Run Windows maintenance tools	Windows Server 2012 R2 and later
Restore default values for Internet Explorer	All AMIs
Restore default values for EC2Config	Windows Server 2012 R2 and earlier
Set EC2Launch to run at the next launch	Windows Server 2016 and 2019
Reset the Windows wallpaper	All AMIs
Run Sysprep	All AMIs

Install and configure

Change	Applies to
Add links to the Amazon EC2 Windows Guide	All AMIs
Attach instance storage volumes to extended mount points	All AMIs
Install the current AWS Tools for Windows PowerShell	All AMIs
Install the current AWS CloudFormation helper scripts	All AMIs
Install the current EC2Config and SSM Agent	Windows Server 2012 R2 and earlier
Install the current EC2Launch and SSM Agent	Windows Server 2016 and 2019
Install the current EC2Launch v2 and SSM Agent	Windows Server 2022 and later

Change	Applies to
Install the current AWS PV, ENA, and NVMe drivers	Windows Server 2008 R2 and later
Install the current SRIOV drivers	Windows Server 2012 R2 and later
Install the current Citrix PV driver	Windows Server 2008 SP2 and earlier
Install the current EC2WinUtil driver	Windows Server 2008 R2 and later
Install PowerShell 2.0 and 3.0	Windows Server 2008 SP2 and R2
If Microsoft SQL Server is installed: <ul style="list-style-type: none"> • Install service packs • Configure to start automatically • Add BUILTIN\Administrators to the SysAdmin role • Open TCP port 1433 and UDP port 1434 	All AMIs
Apply the following hotfixes: <ul style="list-style-type: none"> • MS15-011 • KB2582281 • KB2634328 • KB2800213 • KB2922223 • KB2394911 • KB2780879 	Windows Server 2008 SP2 and R2
Allow ICMP traffic through the firewall	Windows Server 2012 R2 and earlier
Enable file and printer sharing	Windows Server 2012 R2 and earlier
Disable RunOnce for Internet Explorer	All AMIs
Enable remote PowerShell	All AMIs
Configure a paging file on the system volume as follows: <ul style="list-style-type: none"> • Windows Server 2016 and later - Managed by the system • Windows Server 2012 R2 - Initial size and max size are 8 GB • Windows Server 2012 and earlier - Initial size is 512 MB, max size is 8 GB 	All AMIs
Configure an additional system managed paging file on Z:, if available	Windows Server 2012 R2 and earlier
Disable hibernation and delete the hibernation file	All AMIs
Disable the Connected User Experiences and Telemetry service	All AMIs

Change	Applies to
Set the performance options for best performance	All AMIs
Set the power setting to high performance	All AMIs
Disable the screen saver password	All AMIs
Set the RealTimelsUniversal registry key	All AMIs
Set the timezone to UTC	All AMIs
Disable Windows updates and notifications	All AMIs
Run Windows Update and reboot until there are no pending updates	All AMIs
Set the display in all power schemes to never turn off	All AMIs
Set the PowerShell execution policy to "Unrestricted"	All AMIs

Update your Windows instance

After you launch a Windows instance, you are responsible for installing updates on it. For more information, see [Update management in Amazon EC2 \(p. 1694\)](#).

You can manually install only the updates that interest you, or you can start from a current AWS Windows AMI and build a new Windows instance. For information about finding the current AWS Windows AMIs, and keeping your AMIs up to date, see [Find a Windows AMI \(p. 123\)](#) and [Keep your AMIs up to date \(p. 42\)](#).

Note

Instances should be stateless when updating. For more information, see [Managing Your AWS Infrastructure at Scale](#).

For Windows instances, you can install updates to the following services or applications:

- [Windows Server](#)
- [Microsoft SQL Server](#)
- [Windows PowerShell](#)
- [Install the latest version of EC2Launch v2 \(p. 697\)](#)
- [Install the latest version of EC2Launch \(p. 745\)](#)
- [Install the latest version of EC2Config \(p. 755\)](#)
- [AWS Systems Manager SSM Agent](#)
- [Enable enhanced networking on Windows \(p. 1329\)](#)
- [Install or upgrade AWS NVMe drivers using PowerShell \(p. 799\)](#)
- [Upgrade PV drivers on Windows instances \(p. 786\)](#)
- [AWS Tools for Windows PowerShell](#)
- [AWS CloudFormation helper scripts](#)

We recommend that you reboot your Windows instance after installing updates. For more information, see [Reboot your instance \(p. 612\)](#).

Upgrade or migrate to a newer version of Windows Server

For information about how to upgrade or migrate a Windows instance to a newer version of Windows Server, see [Upgrade an Amazon EC2 Windows instance to a newer version of Windows Server \(p. 927\)](#).

Subscribe to Windows AMI notifications

To be notified when new AMIs are released or when previously released AMIs are made private, subscribe to notifications using Amazon SNS.

To subscribe to Windows AMI notifications

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use this Region because the SNS notifications that you are subscribing to were created in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. For the **Create subscription** dialog box, do the following:
 - a. For **Topic ARN**, copy and paste one of the following Amazon Resource Names (ARNs):
 - **arn:aws:sns:us-east-1:801119661308:ec2-windows-ami-update**
 - **arn:aws:sns:us-east-1:801119661308:ec2-windows-ami-private**
6. You'll receive a confirmation email with the subject line AWS Notification - Subscription Confirmation. Open the email and choose **Confirm subscription** to complete your subscription.

Whenever Windows AMIs are released, we send notifications to the subscribers of the ec2-windows-ami-update topic. Whenever released Windows AMIs are made private, we send notifications to the subscribers of the ec2-windows-ami-private topic. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

To unsubscribe from Windows AMI notifications

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use this Region because the SNS notifications were created in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Select the subscriptions and then choose **Delete**. When prompted for confirmation, choose **Delete**.

Changes in Windows Server 2016 and later AMIs

AWS provides AMIs for Windows Server 2016 and later. These AMIs include the following high-level changes from earlier Windows AMIs:

- To accommodate the change from .NET Framework to .NET Core, the EC2Config service has been deprecated on Windows Server 2016 AMIs and replaced by EC2Launch. EC2Launch is a bundle of Windows PowerShell scripts that perform many of the tasks performed by the EC2Config service. For more information, see [Configure a Windows instance using EC2Launch \(p. 743\)](#). EC2Launch v2 replaces EC2Launch in Windows Server 2022 and later. For more information, see [Configure a Windows instance using EC2Launch v2 \(p. 692\)](#).
- On earlier versions of Windows Server AMIs, you can use the EC2Config service to join an EC2 instance to a domain and configure integration with Amazon CloudWatch. On Windows Server 2016 and later AMIs, you can use the CloudWatch agent to configure integration with Amazon CloudWatch. For more information about configuring instances to send log data to CloudWatch, see [Collect Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent](#). For information about joining an EC2 instance to a domain, see [Join an Instance to a Domain Using the AWS-JoinDirectoryServiceDomain JSON Document](#) in the *AWS Systems Manager User Guide*.

Other differences

Note the following additional important differences for instances created from Windows Server 2016 and later AMIs.

- By default, EC2Launch does not initialize secondary EBS volumes. You can configure EC2Launch to initialize disks automatically by either scheduling the script to run or by calling EC2Launch in user data. For the procedure to initialize disks using EC2Launch, see "Initialize Drives and Drive Letter Mappings" in [Configure EC2Launch \(p. 746\)](#).
- If you previously enabled CloudWatch integration on your instances by using a local configuration file (`AWS.EC2.Windows.CloudWatch.json`), you can configure the file to work with the SSM Agent on instances created from Windows Server 2016 and later AMIs.

For more information, see [Windows Server](#) on Microsoft.com.

Specialized Windows AMIs

This section contains information about specialized Windows AMIs, and Windows AMIs developed for Microsoft workload solutions.

Topics

- [SQL Server AMIs provided by AWS \(p. 62\)](#)
- [STIG Hardened Amazon EC2 Windows Server AMIs \(p. 62\)](#)

SQL Server AMIs provided by AWS

To discover available SQL Server license-included AMIs, see [Find a SQL Server license-included AMI](#) in the *Microsoft SQL Server on Amazon EC2 User Guide*.

To view changes to each release of the AWS Windows AMIs, including SQL Server updates, see the [AWS Windows AMI version history](#) in the *Amazon EC2 User Guide*.

STIG Hardened Amazon EC2 Windows Server AMIs

Security Technical Implementation Guides (STIGs) are the configuration standards created by the Defense Information Systems Agency (DISA) to secure information systems and software. DISA documents three levels of compliance risk, known as categories:

- **Category I** — The highest level of risk. It covers the most severe risks, and includes any vulnerability that can result in a loss of confidentiality, availability, or integrity.

- **Category II** — Medium risk.
- **Category III** — Low risk.

Each compliance level includes all STIG settings from lower levels. This means that the highest level includes all applicable settings from all levels.

To ensure that your systems are compliant with STIG standards, you must install, configure, and test a variety of security settings. STIG Hardened EC2 Windows Server AMIs are pre-configured with over 160 required security settings. Amazon EC2 supports the following operating systems for STIG Hardened AMIs:

- Windows Server 2022
- Windows Server 2019
- Windows Server 2016
- Windows Server 2012 R2

The STIG Hardened AMIs include updated Department of Defense (DoD) certificates to help you get started and achieve STIG compliance. STIG Hardened AMIs are available in all public AWS and GovCloud Regions. You can launch instances from these AMIs directly from the Amazon EC2 console. They are billed using standard Windows pricing. There are no additional charges for using STIG Hardened AMIs.

You can find the STIG Hardened EC2 Windows Server AMIs in the Community AMIs when you launch an instance, as follows.

Launch an EC2 instance with a STIG Hardened Windows Server AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Instances** from the navigation pane. This opens a list of your EC2 instances in the current AWS Region.
3. Choose **Launch instances** from the upper right corner above the list. This opens the **Launch an instance** page.
4. To find a STIG Hardened AMI, choose **Browse more AMIs** on the right side of the **Application and OS Images (Amazon Machine Image)** section. This displays an advanced AMI search.
5. Select the **Community AMIs** tab, and enter part or all of one of the following name patterns in the search bar. Our AMIs indicate that they are "provided by Amazon".

Note

The date suffix for the AMI (**YYYY.MM.DD**) is the date when the latest version was created. You can search for the version without the date suffix.

Name patterns for STIG Hardened AMI names

- Windows_Server-2022-English-STIG-Full-**YYYY.MM.DD**
- Windows_Server-2022-English-STIG-Core-**YYYY.MM.DD**
- Windows_Server-2019-English-STIG-Full-**YYYY.MM.DD**
- Windows_Server-2019-English-STIG-Core-**YYYY.MM.DD**
- Windows_Server-2016-English-STIG-Full-**YYYY.MM.DD**
- Windows_Server-2016-English-STIG-Core-**YYYY.MM.DD**
- Windows_Server-2012-R2-English-STIG-Full-**YYYY.MM.DD**
- Windows_Server-2012-R2-English-STIG-Core-**YYYY.MM.DD**

The following sections list the STIG settings that Amazon applies to Windows Operating Systems and components.

Topics

- [Core and base operating systems \(p. 64\)](#)
- [Microsoft .NET Framework 4.0 STIG Version 2 Release 2 \(p. 66\)](#)
- [Windows Firewall STIG Version 2 Release 1 \(p. 66\)](#)
- [Internet Explorer \(IE\) 11 STIG Version 2 Release 3 \(p. 67\)](#)
- [Microsoft Edge STIG Version 1 Release 6 \(p. 67\)](#)
- [Microsoft Defender STIG Version 2 Release 4 \(p. 68\)](#)
- [Version history \(p. 68\)](#)

Core and base operating systems

STIG Hardened EC2 AMIs are designed for use as standalone servers, and have the highest level of STIG settings applied.

The following list contains STIG settings that apply for STIG Hardened Windows AMIs. Not all settings apply in all cases. For example, some STIG settings might not apply to standalone servers. Organization-specific policies can also affect which settings apply, such as a requirement for administrators to review document settings.

For a complete list of Windows STIGs, see the [STIGs Document Library](#). For information about how to view the complete list, see [STIG Viewing Tools](#).

Windows Server 2022 STIG Version 1 Release 1

This release includes the following STIG settings for Windows operating systems:

V-254247, V-254265, V-254269, V-254270, V-254271, V-254272, V-254273, V-254274, V-254276, V-254277, V-254278, V-254285, V-254286, V-254287, V-254288, V-254289, V-254290, V-254291, V-254292, V-254293, V-254300, V-254301, V-254302, V-254303, V-254304, V-254305, V-254306, V-254307, V-254308, V-254309, V-254310, V-254311, V-254312, V-254313, V-254314, V-254315, V-254316, V-254317, V-254318, V-254319, V-254320, V-254321, V-254322, V-254323, V-254324, V-254325, V-254326, V-254327, V-254328, V-254329, V-254330, V-254331, V-254332, V-254333, V-254334, V-254335, V-254336, V-254337, V-254338, V-254339, V-254341, V-254342, V-254344, V-254345, V-254346, V-254347, V-254348, V-254349, V-254350, V-254351, V-254352, V-254353, V-254354, V-254355, V-254356, V-254357, V-254358, V-254359, V-254360, V-254361, V-254362, V-254363, V-254364, V-254365, V-254366, V-254367, V-254368, V-254369, V-254370, V-254371, V-254372, V-254373, V-254374, V-254375, V-254376, V-254377, V-254378, V-254379, V-254380, V-254381, V-254382, V-254383, V-254431, V-254432, V-254433, V-254434, V-254435, V-254436, V-254438, V-254439, V-254442, V-254443, V-254444, V-254445, V-254446, V-254449, V-254450, V-254451, V-254452, V-254453, V-254454, V-254455, V-254456, V-254459, V-254460, V-254461, V-254462, V-254463, V-254464, V-254465, V-254466, V-254467, V-254468, V-254469, V-254470, V-254471, V-254472, V-254473, V-254474, V-254475, V-254476, V-254477, V-254478, V-254479, V-254480, V-254481, V-254482, V-254483, V-254484, V-254485, V-254486, V-254487, V-254488, V-254489, V-254490, V-254493, V-254494, V-254495, V-254497, V-254499, V-254500, V-254501, V-254502, V-254503, V-254504, V-254505, V-254507, V-254508, V-254509, V-254510, V-254511, and V-254512

Windows Server 2019 STIG Version 2 Release 5

This release includes the following STIG settings for Windows operating systems:

V-205625, V-205626, V-205627, V-205628, V-205629, V-205630, V-205631, V-205632, V-205633, V-205634, V-205635, V-205636, V-205637, V-205638, V-205639, V-205640, V-205641, V-205642, V-205643, V-205644, V-205645, V-205646, V-205647, V-205648, V-205649, V-205650, V-205651, V-205652, V-205653, V-205654, V-205655, V-205656, V-205657, V-205658, V-205659, V-205660, V-205661, V-205662, V-205663, V-205664, V-205665, V-205666, V-205667, V-205668, V-205669,

Microsoft .NET Framework 4.0 STIG Version 2 Release 2

The following list contains STIG settings that apply to Windows operating system components for STIG Hardened EC2 AMIs. The following list contains STIG settings that apply for STIG Hardened Windows AMIs. Not all settings apply in all cases. For example, some STIG settings might not apply to standalone servers. Organization-specific policies can also affect which settings apply, such as a requirement for administrators to review document settings.

For a complete list of Windows STIGs, see the [STIGs Document Library](#). For information about how to view the complete list, see [STIG Viewing Tools](#).

.NET Framework on Windows Server 2019, 2016, and 2012 R2 MS

V-225238

Windows Firewall STIG Version 2 Release 1

The following list contains STIG settings that apply to Windows operating system components for STIG Hardened EC2 AMIs. The following list contains STIG settings that apply for STIG Hardened Windows AMIs. Not all settings apply in all cases. For example, some STIG settings might not apply to standalone

servers. Organization-specific policies can also affect which settings apply, such as a requirement for administrators to review document settings.

For a complete list of Windows STIGs, see the [STIGs Document Library](#). For information about how to view the complete list, see [STIG Viewing Tools](#).

Microsoft Edge STIG Version 1 Release 6

The following list contains STIG settings that apply to Windows operating system components for STIG Hardened EC2 AMIs. The following list contains STIG settings that apply for STIG Hardened Windows AMIs. Not all settings apply in all cases. For example, some STIG settings might not apply to standalone servers. Organization-specific policies can also affect which settings apply, such as a requirement for administrators to review document settings.

For a complete list of Windows STIGs, see the [STIGs Document Library](#). For information about how to view the complete list, see [STIG Viewing Tools](#).

2020.9.25	<p>A new version of Amazon Machine Images with SQL Server 2019 dated 2020.09.25 has been released. This release includes the same software components as the previous release dated 2020.09.09 but does not include CU7 for SQL 2019, which has recently been removed from public availability by Microsoft due to a known issue with reliability of the database snapshot feature. For more information, please see the following Microsoft blog post: https://techcommunity.microsoft.com/t5/sql-server/cumulative-update-7-for-sql-server-2019-rtm-removed/ba-p/1629317.</p> <p>New Windows AMIs</p> <ul style="list-style-type: none"> • Windows_Server-2016-English-Full-SQL_2019_Enterprise-2020.09.25 • Windows_Server-2016-English-Full-SQL_2019_Express-2020.09.25 • Windows_Server-2016-English-Full-SQL_2019_Standard-2020.09.25 • Windows_Server-2016-English-Full-SQL_2019_Web-2020.09.25 • Windows_Server-2019-English-Full-SQL_2019_Enterprise-2020.09.25 • Windows_Server-2019-English-Full-SQL_2019_Express-2020.09.25 • Windows_Server-2019-English-Full-SQL_2019_Standard-2020.09.25 • Windows_Server-2019-English-Full-SQL_2019_Web-2020.09.25 <p>EC2LaunchV2_Preview AMIs</p> <ul style="list-style-type: none"> • EC2LaunchV2_Preview-Windows_Server-2019-English-Full-SQL_2019_Express-2020.09.25

Release	Changes
2020.7.01	<p>A new version of Amazon Machine Images has been released. These images include EC2Launch v2 and serve as a functional preview of the new launch agent in advance of it being included by default on all Windows AMIs currently provided by AWS later this year. Note that some SSM documents and dependent services, such as EC2 Image Builder, may require updates to support EC2 Launch v2. These updates will follow in the coming weeks. These images are not recommended for use in production environments. You can read more about EC2Launch v2 at https://aws.amazon.com/about-aws/whats-new/2020/07/introducing-ec2-launch-v2-simplifying-customizing-windows-instances/ and Configure a Windows instance using EC2Launch v2 (p. 692). All current Windows Server AMIs will continue to be provided without changes to the current launch agent, either EC2Config (Server 2012 RTM or 2012 R2) or EC2Launch v1 (Server 2016 or later), for the next several months. In the near future, all Windows Server AMIs currently provided by AWS will be migrated to use EC2Launch v2 by default as part of the monthly release. EC2LaunchV2_Preview AMIs will be updated monthly and remain available until this migration occurs.</p> <p>New Windows AMIs</p> <ul style="list-style-type: none"> • EC2LaunchV2_Preview-Windows_Server-2004-English-Core-Base-2020.06.30 • EC2LaunchV2_Preview-Windows_Server-2019-English-Full-Base-2020.06.30 • EC2LaunchV2_Preview-Windows_Server-2019-English-Core-Base-2020.06.30 • EC2LaunchV2_Preview-Windows_Server-2016-English-Full-Base-2020.06.30 • EC2LaunchV2_Preview-Windows_Server-2016-English-Core-Base-2020.06.30 • EC2LaunchV2_Preview-Windows_Server-2012_R2_RTM-English-Full-Base-2020.06.30 • EC2LaunchV2_Preview-Windows_Server-2012_R2_RTM-English-Core-Base-2020.06.30 • EC2LaunchV2_Preview-Windows_Server-2012_RTM-English-Full-Base-2020.06.30 • EC2LaunchV2_Preview-Windows_Server-2019-English-Full-SQL_2019_Express-2020.06.30 • EC2LaunchV2_Preview-Windows_Server-2016-English-Full-SQL_2017_Express-2020.06.30

Release	Changes
2016.8.26	All Windows Server 2008 R2 AMIs dated 2016.08.11 were updated to fix a known issue. New AMIs are dated 2016.08.25.
2016.8.11	<p>All AMIs</p> <ul style="list-style-type: none"> Ec2Config v3.19.1153 Microsoft security updates current to August 10, 2016 Enabled the registry key User32 exception handler hardening feature in Internet Explorer for MS15-124 <p>Windows Server 2008 R2, Windows Server 2012 RTM, and Windows Server 2012 R2</p> <ul style="list-style-type: none"> Elastic Network Adapter (ENA) Driver 1.0.8.0 ENA AMI property set to enabled AWS PV Driver for Windows Server 2008 R2 was re-released this month because of a known issue. Windows Server 2008 R2 AMI's were removed in July because of this issue.
2016.8.2	All Windows Server 2008 R2 AMIs for July were removed and rolled back to AMIs dated 2016.06.15, because of an issue discovered in the AWS PV driver. The AWS PV driver issue has been fixed. The August AMI release will include Windows Server 2008 R2 AMIs with the fixed AWS PV driver and July/August Windows updates.
2016.7.26	<p>All AMIs</p> <ul style="list-style-type: none"> Ec2Config v3.18.1118 2016.07.13 AMIs were missing security patches. AMIs were re-patched. Additional processes were put in place to verify successful patch installations going forward.
2016.7.13	<p>All AMIs</p> <ul style="list-style-type: none"> Microsoft security updates current to July 2016 Current AWS Tools for Windows PowerShell Updated AWS PV Driver 7.4.2.0 AWS PV Driver for Windows Server 2008 R2
2016.6.16	<p>All AMIs</p> <ul style="list-style-type: none"> Microsoft security updates current to June 2016 Current AWS Tools for Windows PowerShell EC2Config service version 3.17.1032 <p>Microsoft SQL Server</p> <ul style="list-style-type: none"> Released 10 AMIs that include 64-bit versions of Microsoft SQL Server 2016. If using the Amazon EC2 console, navigate to Images, AMIs, Public Images, and type Windows_Server-2012-R2_RTM-English-64Bit-SQL_2016_Standard in the search bar. For more information, see What's New in SQL Server 2016 on MSDN.

Find a Windows AMI

Before you can launch an instance, you must select an AMI from which to launch the instance. When you select an AMI, consider the following requirements you might have for the instances that you want to launch:

- The Region
- The operating system
- The architecture: 32-bit (i386) or 64-bit (x86_64)
- The provider (for example, Amazon Web Services)
- Additional software (for example, SQL Server)

If you want to find an Ubuntu AMI, see their [EC2 AMI Locator](#).

If you want to find a RedHat AMI, see the RHEL [knowledgebase article](#).

If you want to find a Linux AMI, see [Find a Linux AMI](#) in the *Amazon EC2 User Guide for Linux Instances*.

Find a Windows AMI topics

- [Find a Windows AMI using the Amazon EC2 console \(p. 124\)](#)
- [Find an AMI using the AWS Tools for Windows PowerShell \(p. 125\)](#)
- [Find an AMI using the AWS CLI \(p. 125\)](#)
- [Find the latest Windows AMI using Systems Manager \(p. 125\)](#)
- [Use a Systems Manager parameter to find an AMI \(p. 126\)](#)

Find a Windows AMI using the Amazon EC2 console

You can find Windows AMIs using the Amazon EC2 console. You can select from the list of AMIs when you use the launch instance wizard to launch an instance, or you can search through all available AMIs using the **Images** page. AMI IDs are unique to each AWS Region.

To find a Windows AMI using the launch instance wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. From the console dashboard, choose **Launch instance**.
4. (New console) Under **Application and OS Images (Amazon Machine Image)**, choose **Quick Start**, choose the operating system (OS) for your instance, and then, from **Amazon Machine Image (AMI)**, select from one of the commonly used AMIs in the list. If you don't see the AMI that you want to use, choose **Browse more AMIs** to browse the full AMI catalog. For more information, see [Application and OS Images \(Amazon Machine Image\) \(p. 555\)](#).

(Old console) On the **Quick Start** tab, select from one of the commonly used AMIs in the list. If you don't see the AMI that you want to use, choose the **My AMIs**, **AWS Marketplace**, or **Community AMIs** tab to find additional AMIs. For more information, see [Step 1: Choose an Amazon Machine Image \(AMI\) \(p. 562\)](#).

To find a Windows AMI using the AMIs page

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. In the navigation pane, choose **AMIs**.
4. (Optional) Use the filter and search options to scope the list of displayed AMIs to see only the AMIs that match your criteria. For example, to list all Windows AMIs provided by AWS, choose **Public images**. Then use the search options to further scope the list of displayed AMIs.

(New console) Choose the **Search** bar and, from the menu, choose **Owner alias**, then the = operator, and then the value **amazon**. Choose the **Search** bar again to choose **Platform**, then the = operator, and then the operating system from the list provided.

(Old console) Choose the **Search** bar and, from the menu, choose **Owner** and then the value **Amazon images**. Choose the **Search** bar again to choose **Platform** and then the operating system from the list provided.

5. (Optional) Choose the **Preferences** icon (new console) or **Show/Hide Columns** icon (old console) to select which image attributes to display, such as the root device type. Alternatively, you can select an AMI from the list and view its properties on the **Details** tab.
6. To launch an instance from this AMI, select it and then choose **Launch instance from image** (new console) or **Launch** (old console). For more information about launching an instance using the console, see [Launch an instance using the new launch instance wizard \(p. 552\)](#). If you're not ready to launch the instance now, make note of the AMI ID for later.

Find an AMI using the AWS Tools for Windows PowerShell

You can use PowerShell cmdlets for Amazon EC2 or AWS Systems Manager to list only the Windows AMIs that match your requirements. After locating an AMI that matches your requirements, make note of its ID so that you can use it to launch instances. For more information, see [Launch an Instance Using Windows PowerShell](#) in the *AWS Tools for Windows PowerShell User Guide*.

Amazon EC2

For information and examples, see [Find an AMI Using Windows PowerShell](#) in the *AWS Tools for Windows PowerShell User Guide*.

Systems Manager Parameter Store

For information and examples, see [Query for the Latest Windows AMI Using Systems Manager Parameter Store](#).

Find an AMI using the AWS CLI

You can use AWS CLI commands for Amazon EC2 or AWS Systems Manager to list only the Windows AMIs that match your requirements. After locating an AMI that matches your requirements, make note of its ID so that you can use it to launch instances. For more information, see [Launch your instance](#) in the *AWS Command Line Interface User Guide*.

Amazon EC2

The [describe-images](#) command supports filtering parameters. For example, use the `--owners` parameter to display public AMIs owned by Amazon.

```
aws ec2 describe-images --owners self amazon
```

You can add the following filter to the previous command to display only Windows AMIs.

```
--filters "Name=platform,Values=windows"
```

Important

Omitting the `--owners` flag from the `describe-images` command returns all images for which you have launch permissions, regardless of ownership.

Systems Manager Parameter Store

For information and examples, see [Query for the Latest Windows AMI Using Systems Manager Parameter Store](#).

Find the latest Windows AMI using Systems Manager

Amazon EC2 provides AWS Systems Manager public parameters for public AMIs maintained by AWS that you can use when launching instances.

To find the latest Amazon Linux 2023 AMI using AWS Systems Manager, see [Get started with Amazon Linux 2023](#).

The Amazon EC2 AMI public parameters are available from the following path:

/aws/service/ami-windows-latest

You can view a list of all Windows AMIs in the current AWS Region by running the following AWS CLI command.

```
aws ssm get-parameters-by-path --path /aws/service/ami-windows-latest --query "Parameters[].[Name]"
```

For more information, see [Using public parameters](#) in the *AWS Systems Manager User Guide* and [Query for the Latest Windows AMI Using AWS Systems Manager Parameter Store](#).

Use a Systems Manager parameter to find an AMI

When you launch an instance using the EC2 launch instance wizard in the console, you can either select an AMI from the list, or you can select an AWS Systems Manager parameter that points to an AMI ID. If you use automation code to launch your instances, you can specify the Systems Manager parameter instead of the AMI ID.

A Systems Manager parameter is a customer-defined key-value pair that you can create in Systems Manager Parameter Store. The Parameter Store provides a central store to externalize your application configuration values. For more information, see [AWS Systems Manager Parameter Store](#) in the *AWS Systems Manager User Guide*.

When you create a parameter that points to an AMI ID, make sure that you specify the data type as `aws:ec2:image`. Specifying this data type ensures that when the parameter is created or modified, the parameter value is validated as an AMI ID. For more information, see [Native parameter support for Amazon Machine Image IDs](#) in the *AWS Systems Manager User Guide*.

Systems Manager parameter topics

- [Use cases \(p. 126\)](#)
- [Permissions \(p. 127\)](#)
- [Limitations \(p. 127\)](#)
- [Launch an instance using a Systems Manager parameter \(p. 127\)](#)

Use cases

When you use Systems Manager parameters to point to AMI IDs, it is easier for your users to select the correct AMI when launching instances. Systems Manager parameters can also simplify the maintenance of automation code.

Easier for users

If you require instances to be launched using a specific AMI, and the AMI is regularly updated, we recommend that you require your users to select a Systems Manager parameter to find the AMI. Requiring your users to select a Systems Manager parameter ensures that the latest AMI is used to launch instances.

For example, every month in your organization you might create a new version of your AMI that has the latest operating system and application patches. You also require your users to launch instances using the latest version of your AMI. To ensure that your users use the latest version, you can create a Systems Manager parameter (for example, `golden-ami`) that points to the correct AMI ID. Each time a new version of the AMI is created, you update the AMI ID value in the parameter so that it always points to the latest AMI. Your users don't have to know about the periodic updates to the AMI because they continue to select the same Systems Manager parameter each time. Using a Systems Manager parameter for your AMI makes it easier for them to select the correct AMI for an instance launch.

Simplify automation code maintenance

If you use automation code to launch your instances, you can specify the Systems Manager parameter instead of the AMI ID. If a new version of the AMI is created, you can change the AMI ID value in the parameter so that it points to the latest AMI. The automation code that references the parameter doesn't have to be modified each time a new version of the AMI is created. This simplifies the maintenance of the automation and helps to drive down deployment costs.

Note

Running instances are not affected when you change the AMI ID pointed to by the Systems Manager parameter.

Permissions

If you use Systems Manager parameters that point to AMI IDs in the launch instance wizard, you must add `ssm:DescribeParameters` and `ssm:GetParameters` to your IAM policy. `ssm:DescribeParameters` grants your users permission to view and select Systems Manager parameters. `ssm:GetParameters` grants your users permission to retrieve the values of the Systems Manager parameters. You can also restrict access to specific Systems Manager parameters. For more information, see [Use the EC2 launch instance wizard \(p. 1640\)](#).

Limitations

AMIs and Systems Manager parameters are Region specific. To use the same Systems Manager parameter name across Regions, create a Systems Manager parameter in each Region with the same name (for example, `golden-ami`). In each Region, point the Systems Manager parameter to an AMI in that Region.

Launch an instance using a Systems Manager parameter

You can launch an instance using the console or the AWS CLI. Instead of specifying an AMI ID, you can specify an AWS Systems Manager parameter that points to an AMI ID.

New console

To find a Windows AMI using a Systems Manager parameter (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. From the console dashboard, choose **Launch instance**.
4. Under **Application and OS Images (Amazon Machine Image)**, choose **Browse more AMIs**.
5. Choose the arrow button to the right of the search bar, and then choose **Search by Systems Manager parameter**.
6. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears below **Currently resolves to**.
7. Choose **Search**. The AMIs that match the AMI ID appear in the list.
8. Select the AMI from the list, and choose **Select**.

For more information about launching an instance using the launch instance wizard, see [Launch an instance using the new launch instance wizard \(p. 552\)](#).

Old console

To find a Windows AMI using a Systems Manager parameter (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. From the console dashboard, choose **Launch instance**.
4. Choose **Search by Systems Manager parameter** (at top right).
5. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears next to **Currently resolves to**.
6. Choose **Search**. The AMIs that match the AMI ID appear in the list.
7. Select the AMI from the list, and choose **Select**.

For more information about launching an instance from an AMI using the launch instance wizard, see [Step 1: Choose an Amazon Machine Image \(AMI\) \(p. 562\)](#).

To launch an instance using an AWS Systems Manager parameter instead of an AMI ID (AWS CLI)

The following example uses the Systems Manager parameter `golden-ami` to launch an `m5.xlarge` instance. The parameter points to an AMI ID.

To specify the parameter in the command, use the following syntax: `resolve:ssm:/parameter-name`, where `resolve:ssm` is the standard prefix and `parameter-name` is the unique parameter name. Note that the parameter name is case-sensitive. Backslashes for the parameter name are only necessary when the parameter is part of a hierarchy, for example, `/amis/production/golden-ami`. You can omit the backslash if the parameter is not part of a hierarchy.

In this example, the `--count` and `--security-group` parameters are not included. For `--count`, the default is 1. If you have a default VPC and a default security group, they are used.

```
aws ec2 run-instances
  --image-id resolve:ssm:/golden-ami
  --instance-type m5.xlarge
  ...
```

To launch an instance using a specific version of an AWS Systems Manager parameter (AWS CLI)

Systems Manager parameters have version support. Each iteration of a parameter is assigned a unique version number. You can reference the version of the parameter as follows `resolve:ssm:parameter-name:version`, where `version` is the unique version number. By default, the latest version of the parameter is used when no version is specified.

The following example uses version 2 of the parameter.

In this example, the `--count` and `--security-group` parameters are not included. For `--count`, the default is 1. If you have a default VPC and a default security group, they are used.

```
aws ec2 run-instances
  --image-id resolve:ssm:/golden-ami:2
  --instance-type m5.xlarge
  ...
```

To launch an instance using a public parameter provided by AWS

Amazon EC2 provides Systems Manager public parameters for public AMIs provided by AWS. For example, the public parameter `/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2` is available in all Regions, and always points to the latest version of the Amazon Linux 2 AMI in the Region.

```
aws ec2 run-instances
  --image-id resolve:ssm:/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2
```

```
--instance-type m5.xlarge  
...
```

Shared AMIs

A *shared AMI* is an AMI that a developer created and made available for others to use. One of the easiest ways to get started with Amazon EC2 is to use a shared AMI that has the components you need and then add custom content. You can also create your own AMIs and share them with others.

You use a shared AMI at your own risk. Amazon can't vouch for the integrity or security of AMIs shared by other Amazon EC2 users. Therefore, you should treat shared AMIs as you would any foreign code that you might consider deploying in your own data center, and perform the appropriate due diligence. We recommend that you get an AMI from a trusted source, such as a verified provider.

Verified provider

In the Amazon EC2 console, public AMIs that are owned by Amazon or a verified Amazon partner are marked **Verified provider**.

You can also use the [describe-images](#) AWS CLI command to identify the public AMIs that come from a verified provider. Public images that are owned by Amazon or a verified partner have an aliased owner, which is either amazon or aws-marketplace. In the CLI output, these values appear for ImageOwnerAlias. Other users can't alias their AMIs. This enables you to easily find AMIs from Amazon or verified partners.

To become a verified provider, you must register as a seller on the AWS Marketplace. Once registered, you can list your AMI on the AWS Marketplace. For more information, see [Getting started as a seller](#) and [AMI-based products](#) in the *AWS Marketplace Seller Guide*.

Shared AMI topics

- [Find shared AMIs \(p. 129\)](#)
- [Make an AMI public \(p. 132\)](#)
- [Share an AMI with specific organizations or organizational units \(p. 134\)](#)
- [Share an AMI with specific AWS accounts \(p. 141\)](#)
- [Cancel having an AMI shared with your AWS account \(p. 145\)](#)
- [Use bookmarks \(p. 146\)](#)
- [Best practices for shared Windows AMIs \(p. 146\)](#)

If you're looking for information about other topics

- For information about creating an AMI, see [Create a custom Windows AMI](#).
- For information about building, delivering, and maintaining your applications on the AWS Marketplace, see the [AWS Marketplace Documentation](#).

Find shared AMIs

You can use the Amazon EC2 console or the command line to find shared AMIs.

AMIs are a Regional resource. When you search for a shared AMI (public or private), you must search for it from the same Region from which it is shared. To make an AMI available in a different Region, copy the AMI to the Region, and then share it. For more information, see [Copy an AMI \(p. 166\)](#).

Topics

- [Find a shared AMI \(console\) \(p. 130\)](#)
- [Find a shared AMI \(Tools for Windows PowerShell\) \(p. 130\)](#)
- [Find a shared AMI \(AWS CLI\) \(p. 131\)](#)

Find a shared AMI (console)

To find a shared private AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose **Private images**. All AMIs that have been shared with you are listed. To granulate your search, choose the **Search** bar and use the filter options provided in the menu.

To find a shared public AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose **Public images**. To granulate your search, choose the **Search** field and use the filter options provided in the menu.

To find Amazon's shared public AMIs using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose **Public images**.
4. Choose the **Search** field and then, from the menu options that appear, choose **Owner alias**, then **=**, and then **amazon** to display only Amazon's public images.

To find a shared public AMI from a verified provider using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMI Catalog**.
3. Choose **Community AMIs**.
4. The **Verified provider** label indicates the AMIs that are from Amazon or a verified partner.

Find a shared AMI (Tools for Windows PowerShell)

Use the [Get-EC2Image](#) command (Tools for Windows PowerShell) to list AMIs. You can scope the list to the types of AMIs that interest you, as shown in the following examples.

Example: List all public AMIs

The following command lists all public AMIs, including any public AMIs that you own.

```
PS C:\> Get-EC2Image -ExecutableUser all
```

Example: List AMIs with explicit launch permissions

The following command lists the AMIs for which you have explicit launch permissions. This list does not include any AMIs that you own.

```
PS C:\> Get-EC2Image -ExecutableUser self
```

Example: List AMIs owned by verified providers

The following command lists the AMIs owned by verified providers. Public AMIs owned by verified providers (either Amazon or verified partners) have an aliased owner, which appears as amazon or aws-marketplace in the account field. This helps you to easily find AMIs from verified providers. Other users can't alias their AMIs.

```
PS C:\> Get-EC2Image -Owner amazon aws-marketplace
```

Example: List AMIs owned by an account

The following command lists the AMIs owned by the specified AWS account.

```
PS C:\> Get-EC2Image -Owner 123456789012
```

Example: Scope AMIs using a filter

To reduce the number of displayed AMIs, use a filter to list only the types of AMIs that interest you. For example, use the following filter to display only EBS-backed AMIs.

```
-Filter @{ Name="root-device-type"; Values="ebs" }
```

Find a shared AMI (AWS CLI)

Use the [describe-images](#) command (AWS CLI) to list AMIs. You can scope the list to the types of AMIs that interest you, as shown in the following examples.

Example: List all public AMIs

The following command lists all public AMIs, including any public AMIs that you own.

```
aws ec2 describe-images --executable-users all
```

Example: List AMIs with explicit launch permissions

The following command lists the AMIs for which you have explicit launch permissions. This list does not include any AMIs that you own.

```
aws ec2 describe-images --executable-users self
```

Example: List AMIs owned by verified providers

The following command lists the AMIs owned by verified providers. Public AMIs owned by verified providers (either Amazon or verified partners) have an aliased owner, which appears as amazon or aws-marketplace in the account field. This helps you to easily find AMIs from verified providers. Other users can't alias their AMIs.

```
aws ec2 describe-images \
```

```
--owners amazon aws-marketplace \
--query 'Images[*].[ImageId]' \
--output text
```

Example: List AMIs owned by an account

The following command lists the AMIs owned by the specified AWS account.

```
aws ec2 describe-images --owners 123456789012
```

Example: Scope AMIs using a filter

To reduce the number of displayed AMIs, use a filter to list only the types of AMIs that interest you. For example, use the following filter to display only EBS-backed AMIs.

```
--filters "Name=root-device-type,Values=ebs"
```

Make an AMI public

You can share your AMIs with other AWS accounts. To allow all AWS accounts to use an AMI to launch instances, make the AMI public. To allow only specific accounts to use the AMI to launch instances, see [Share an AMI with specific AWS accounts \(p. 141\)](#).

Public AMI topics

- [Considerations \(p. 132\)](#)
- [Share an AMI with all AWS accounts \(console\) \(p. 133\)](#)
- [Share an AMI with all AWS accounts \(Tools for Windows PowerShell\) \(p. 133\)](#)
- [Share an AMI with all AWS accounts \(AWS CLI\) \(p. 134\)](#)

Considerations

Consider the following before making an AMI public.

- **Ownership** – To make an AMI public, your AWS account must own the AMI.
- **Some AMIs can't be made public** – If your AMI includes one of the following components, you can't make it public (but you can [share the AMI with specific AWS accounts \(p. 141\)](#)):
 - Encrypted volumes
 - Snapshots of encrypted volumes
 - Product codes
- **Region** – AMIs are a Regional resource. When you share an AMI, it is available only in the Region from which you shared it. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see [Copy an AMI \(p. 166\)](#).
- **Usage** – When you share an AMI, users can only launch instances from the AMI. They can't delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from the instance they launched.
- **Automatic depreciation** – By default, the deprecation date of all public AMIs is set to two years from the AMI creation date. You can set the deprecation date to earlier than two years. To cancel the deprecation date, or to move the deprecation to a later date, you must make the AMI private by only [sharing it with specific AWS accounts \(p. 141\)](#).
- **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

Share an AMI with all AWS accounts (console)

After you make an AMI public, it is available in **Community AMIs** when you launch an instance in the same Region using the console. Note that it can take a short while for an AMI to appear in **Community AMIs** after you make it public. It can also take a short while for an AMI to be removed from **Community AMIs** after you make it private.

New console

To share a public AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI from the list, and then choose **Actions, Edit AMI permissions**.
4. Choose **Public**, and then choose **Save changes**.

Old console

To share a public AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI from the list, and then choose **Actions, Modify Image Permissions**.
4. Choose **Public**, and then choose **Save**.

Share an AMI with all AWS accounts (Tools for Windows PowerShell)

Each AMI has a `launchPermission` property that controls which AWS accounts, besides the owner's, are allowed to use that AMI to launch instances. By modifying the `launchPermission` property of an AMI, you can make the AMI public (which grants launch permissions to all AWS accounts), or share it with only the AWS accounts that you specify.

You can add or remove account IDs from the list of accounts that have launch permissions for an AMI. To make the AMI public, specify the `all` group. You can specify both public and explicit launch permissions.

To make an AMI public

1. Use the [Edit-EC2ImageAttribute](#) command as follows to add the `all` group to the `launchPermission` list for the specified AMI.

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute
          launchPermission -OperationType add -UserGroup all
```

2. To verify the launch permissions of the AMI, use the following [Get-EC2ImageAttribute](#) command.

```
PS C:\> Get-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute
          launchPermission
```

3. (Optional) To make the AMI private again, remove the `all` group from its launch permissions. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission -OperationType remove -UserGroup all
```

Share an AMI with all AWS accounts (AWS CLI)

Each AMI has a `launchPermission` property that controls which AWS accounts, besides the owner's, are allowed to use that AMI to launch instances. By modifying the `launchPermission` property of an AMI, you can make the AMI public (which grants launch permissions to all AWS accounts), or share it with only the AWS accounts that you specify.

You can add or remove account IDs from the list of accounts that have launch permissions for an AMI. To make the AMI public, specify the `all` group. You can specify both public and explicit launch permissions.

To make an AMI public

1. Use the [modify-image-attribute](#) command as follows to add the `all` group to the `launchPermission` list for the specified AMI.

```
aws ec2 modify-image-attribute \  
  --image-id ami-0abcdef1234567890 \  
  --launch-permission "Add=[{Group=all}]"
```

2. To verify the launch permissions of the AMI, use the [describe-image-attribute](#) command.

```
aws ec2 describe-image-attribute \  
  --image-id ami-0abcdef1234567890 \  
  --attribute launchPermission
```

3. (Optional) To make the AMI private again, remove the `all` group from its launch permissions. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 modify-image-attribute \  
  --image-id ami-0abcdef1234567890 \  
  --launch-permission "Remove=[{Group=all}]"
```

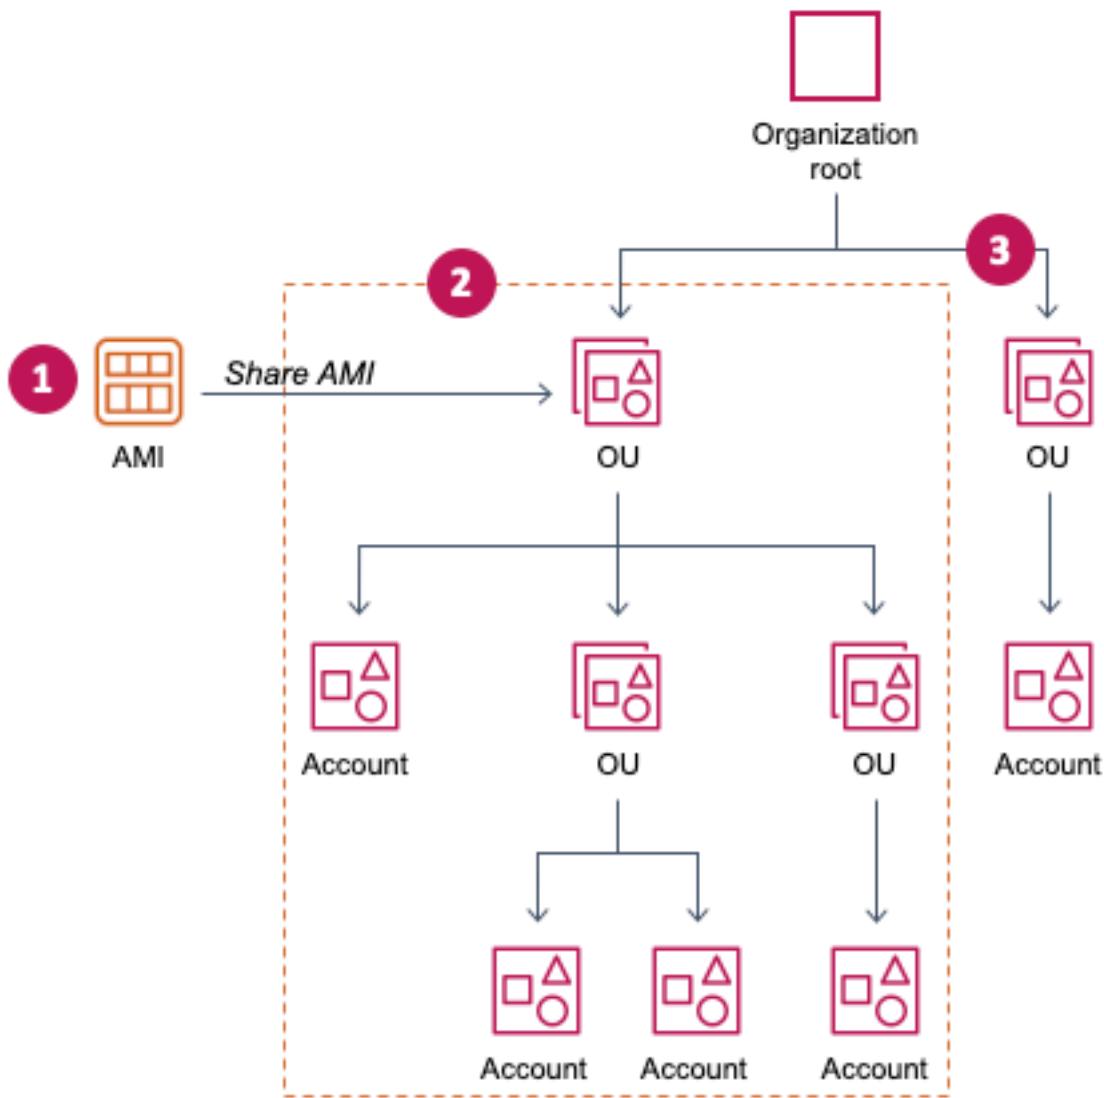

Share an AMI with specific organizations or organizational units

[AWS Organizations](#) is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage. You can share an AMI with an organization or an organizational unit (OU) that you have created, in addition to [sharing it with specific accounts \(p. 141\)](#).

An organization is an entity that you create to consolidate and centrally manage your AWS accounts. You can organize the accounts in a hierarchical, tree-like structure, with a [root](#) at the top and [organizational units](#) nested under the organization root. Each account can be added directly to the root, or placed in one of the OUs in the hierarchy. For more information, see [AWS Organizations terminology and concepts](#) in the [AWS Organizations User Guide](#).

When you share an AMI with an organization or an OU, all of the children accounts gain access to the AMI. For example, in the following diagram, the AMI is shared with a top-level OU (indicated by the arrow at the number 1). All of the OUs and accounts that are nested underneath that top-level OU

(indicated by the dotted line at number 2) also have access to the AMI. The accounts in the organization and OU outside the dotted line (indicated by the number 3) do not have access to the AMI because they are not children of the OU that the AMI is shared with.

Considerations

Consider the following when sharing AMIs with specific organizations or organizational units.

- **Ownership** – To share an AMI, your AWS account must own the AMI.
- **Sharing limits** – The AMI owner can share an AMI with any organization or OU, including organizations and OUs that they're not a member of.

For the maximum number of entities to which an AMI can be shared within a Region, see the [Amazon EC2 service quotas](#).

- **Tags** – You can't share user-defined tags (tags that you attach to an AMI). When you share an AMI, your user-defined tags are not available to any AWS account in an organization or OU with which the AMI is shared.

- **ARN format** – When you specify an organization or OU in a command, make sure to use the correct ARN format. You'll get an error if you specify only the ID, for example, if you specify only o-123example or ou-1234-5example.

Correct ARN formats:

- Organization ARN: `arn:aws:organizations::account-id:organization/organization-id`
- OU ARN: `arn:aws:organizations::account-id:ou/organization-id/ou-id`

Where:

- **account-id** is the 12-digit management account number, for example, 123456789012. If you don't know the management account number, you can describe the organization or the organizational unit to get the ARN, which includes the management account number. For more information, see [Get the ARN \(p. 141\)](#).
- **organization-id** is the organization ID, for example, o-123example.
- **ou-id** is the organizational unit ID, for example, ou-1234-5example.

For more information about the format of ARNs, see [Amazon Resource Names \(ARNs\)](#) in the *AWS General Reference*.

- **Encryption and keys** – You can share AMIs that are backed by unencrypted and encrypted snapshots.
 - The encrypted snapshots must be encrypted with a customer managed key. You can't share AMIs that are backed by snapshots that are encrypted with the default AWS managed key. For more information, see [Share an Amazon EBS snapshot \(p. 1810\)](#).
 - If you share an AMI that is backed by encrypted snapshots, you must allow the organizations or OUs to use the customer managed keys that were used to encrypt the snapshots. For more information, see [Allow organizations and OUs to use a KMS key \(p. 136\)](#).
- **Region** – AMIs are a Regional resource. When you share an AMI, it is available only in the Region from which you shared it. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see [Copy an AMI \(p. 166\)](#).
- **Usage** – When you share an AMI, users can only launch instances from the AMI. They can't delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from the instance they launched.
- **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

Allow organizations and OUs to use a KMS key

If you share an AMI that is backed by encrypted snapshots, you must also allow the organizations or OUs to use the AWS KMS keys that were used to encrypt the snapshots.

Use the `aws:PrincipalOrgID` and `aws:PrincipalOrgPaths` keys to compare the AWS Organizations path for the principal who is making the request to the path in the policy. That principal can be a user, IAM role, federated user, or AWS account root user. In a policy, this condition key ensures that the requester is an account member within the specified organization root or OUs in AWS Organizations. For more example condition statements, see [aws:PrincipalOrgID](#) and [aws:PrincipalOrgPaths](#) in the *IAM User Guide*.

For information about editing a key policy, see [Allowing users in other accounts to use a KMS key](#) in the *AWS Key Management Service Developer Guide* and [Share a KMS key \(p. 1812\)](#).

To give an organization or OU permission to use a KMS key, add the following statement to the key policy.

```
{  
    "Sid": "Allow access for organization root",
```

```
"Effect": "Allow",
"Principal": "*",
>Action": [
    "kms:Describe*",
    "kms>List*",
    "kms:Get*",
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*"
],
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:PrincipalOrgID": "o-123example"
    }
}
}
```

To share a KMS key with multiple OUs, you can use a policy similar to the following example.

```
{
    "Sid": "Allow access for specific OUs and their descendants",
    "Effect": "Allow",
    "Principal": "*",
    "Action": [
        "kms:Describe*",
        "kms>List*",
        "kms:Get*",
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:PrincipalOrgID": "o-123example"
        },
        "ForAnyValue:StringLike": {
            "aws:PrincipalOrgPaths": [
                "o-123example/r-ab12/ou-ab12-33333333/*",
                "o-123example/r-ab12/ou-ab12-22222222/*"
            ]
        }
    }
}
```

Share an AMI

You can use the Amazon EC2 console or the AWS CLI to share an AMI with an organization or OU.

Share an AMI (console)

To share an AMI with an organization or an OU using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions**, **Edit AMI permissions**.
4. Under **AMI availability**, choose **Private**.
5. Next to **Shared organizations/OUs**, choose **Add organization/OU ARN**.

6. For **Organization/OU ARN**, enter the organization ARN or OU ARN with which you want to share the AMI, and then choose **Share AMI**. Note that you must specify the full ARN, not just the ID.

To share this AMI with multiple organizations or OUs, repeat this step until you have added all of the required organizations or OUs.

Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared, and the system automatically provides the instance with access to the referenced Amazon EBS snapshots for the launch. However, you do need to share the KMS keys used to encrypt snapshots that the AMI references. For more information, see [Allow organizations and OUs to use a KMS key \(p. 136\)](#).

7. Choose **Save changes** when you're done.
8. (Optional) To view the organizations or OUs with which you have shared the AMI, select the AMI in the list, choose the **Permissions** tab, and scroll down to **Shared organizations/OUs**. To find AMIs that are shared with you, see [Find shared AMIs \(p. 129\)](#).

Share an AMI (Tools for Windows PowerShell)

Use the [Edit-EC2ImageAttribute](#) command (Tools for Windows PowerShell) to share an AMI as shown in the following examples.

To share an AMI with an organization or an OU

The following command grants launch permissions for the specified AMI to the specified organization.

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -  
Attribute launchPermission -OperationType add -OrganizationArn  
"arn:aws:organizations::123456789012:organization/o-123example"
```

Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared, and the system automatically provides the instance with access to the referenced Amazon EBS snapshots for the launch. However, you do need to share the KMS keys used to encrypt snapshots that the AMI references. For more information, see [Allow organizations and OUs to use a KMS key \(p. 136\)](#).

To stop sharing an AMI with an organization or OU

The following command removes launch permissions for the specified AMI from the specified organization:

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -  
Attribute launchPermission -OperationType remove -OrganizationArn  
"arn:aws:organizations::123456789012:organization/o-123example"
```

To stop sharing an AMI with all organizations, OUs, and AWS accounts

The following command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
PS C:\> Reset-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission
```

Share an AMI (AWS CLI)

Use the [modify-image-attribute](#) command (AWS CLI) to share an AMI.

To share an AMI with an organization using the AWS CLI

The [modify-image-attribute](#) command grants launch permissions for the specified AMI to the specified organization. Note that you must specify the full ARN, not just the ID.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
--launch-permission
"Add=[{OrganizationArn=arn:aws:organizations::123456789012:organization/o-123example}]"
```

To share an AMI with an OU using the AWS CLI

The [modify-image-attribute](#) command grants launch permissions for the specified AMI to the specified OU. Note that you must specify the full ARN, not just the ID.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
--launch-permission
"Add=[{OrganizationalUnitArn=arn:aws:organizations::123456789012:ou/o-123example/
ou-1234-5example}]"
```

Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared, and the system automatically provides the instance with access to the referenced Amazon EBS snapshots for the launch. However, you do need to share the KMS keys used to encrypt snapshots that the AMI references. For more information, see [Allow organizations and OUs to use a KMS key \(p. 136\)](#).

Stop sharing an AMI

You can use the Amazon EC2 console or the AWS CLI to stop sharing an AMI with an organization or OU.

Stop sharing an AMI (console)

To stop sharing an AMI with an organization or OU using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions, Edit AMI permissions**.
4. Under **Shared organizations/OUs**, select the organizations or OUs with which you want to stop sharing the AMI, and then choose **Remove selected**.
5. Choose **Save changes** when you're done.
6. (Optional) To confirm that you have stopped sharing the AMI with the organizations or OUs, select the AMI in the list, choose the **Permissions** tab, and scroll down to **Shared organizations/OUs**.

Stop sharing an AMI (AWS CLI)

Use the [modify-image-attribute](#) or [reset-image-attribute](#) commands (AWS CLI) to stop sharing an AMI.

To stop sharing an AMI with an organization or OU using the AWS CLI

The [modify-image-attribute](#) command removes launch permissions for the specified AMI from the specified organization. Note that you must specify the ARN.

```
aws ec2 modify-image-attribute \
--image-id ami-0abcdef1234567890 \
```

```
--launch-permission  
"Remove=[{OrganizationArn=arn:aws:organizations::123456789012:organization/o-123example}]"
```

To stop sharing an AMI with all organizations, OUs, and AWS accounts using the AWS CLI

The [reset-image-attribute](#) command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 reset-image-attribute \  
--image-id ami-0abcdef1234567890 \  
--attribute launchPermission
```

Note

You can't stop sharing an AMI with a specific account if it's in an organization or OU with which an AMI is shared. If you try to stop sharing the AMI by removing launch permissions for the account, Amazon EC2 returns a success message. However, the AMI continues to be shared with the account.

View the organizations and OUs with which an AMI is shared

You can use the Amazon EC2 console or the AWS CLI to check with which organizations and OUs you've shared your AMI.

View the organizations and OUs with which an AMI is shared (console)

To check with which organizations and OUs you've shared your AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, choose the **Permissions** tab, and scroll down to **Shared organizations/OUs**.

To find AMIs that are shared with you, see [Find shared AMIs \(p. 129\)](#).

View the organizations and OUs with which an AMI is shared (AWS CLI)

You can check which organizations and OUs you've shared your AMI with by using the [describe-image-attribute](#) command (AWS CLI) and the `launchPermission` attribute.

To check with which organizations and OUs you've shared your AMI using the AWS CLI

The [describe-image-attribute](#) command describes the `launchPermission` attribute for the specified AMI, and returns the organizations and OUs with which you've shared the AMI.

```
aws ec2 describe-image-attribute \  
--image-id ami-0abcdef1234567890 \  
--attribute launchPermission
```

Example response

```
{  
    "ImageId": "ami-0abcdef1234567890",  
    "LaunchPermissions": [  
        {  
            "OrganizationalUnitArn": "arn:aws:organizations::111122223333:ou/o-123example/  
ou-1234-5example"  
        }  
    ]  
}
```

}

Get the ARN

The organization and the organizational unit ARNs contain the 12-digit management account number. If you don't know the management account number, you can describe the organization and the organizational unit to get the ARN for each. In the following examples, 123456789012 is the management account number.

Before you can get the ARNs, you must have the permission to describe organizations and organizational units. The following policy provides the necessary permission.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "organizations:Describe*",  
                ],  
            "Resource": "*"  
        }  
    ]  
}
```

To get the ARN of an organization

Use the [describe-organization](#) command and the --query parameter set to 'Organization.Arn' to return only the organization ARN.

```
aws organizations describe-organization --query 'Organization.Arn'
```

Example response

"arn:aws:organizations::123456789012:organization/o-123example"

To get the ARN of an organizational unit

Use the [describe-organizational-unit](#) command, specify the OU ID, and set the --query parameter to 'OrganizationalUnit.Arn' to return only the organizational unit ARN.

```
aws organizations describe-organizational-unit --organizational-unit-id ou-1234-5example --query 'OrganizationalUnit.Arn'
```

Example response

"arn:aws:organizations::123456789012:ou/o-123example/ou-1234-5example"

Share an AMI with specific AWS accounts

You can share an AMI with specific AWS accounts without making the AMI public. All you need are the AWS account IDs.

An AWS account ID is a 12-digit number, such as 012345678901, that uniquely identifies an AWS account. For more information, see [Viewing AWS account identifiers](#) in the *AWS Account Management Reference Guide*.

Considerations

Consider the following when sharing AMIs with specific AWS accounts.

- **Ownership** – To share an AMI, your AWS account must own the AMI.
- **Sharing limits** – For the maximum number of entities to which an AMI can be shared within a Region, see the [Amazon EC2 service quotas](#).
- **Tags** – You can't share user-defined tags (tags that you attach to an AMI). When you share an AMI, your user-defined tags are not available to any AWS account that the AMI is shared with.
- **Encryption and keys** – You can share AMIs that are backed by unencrypted and encrypted snapshots.
 - The encrypted snapshots must be encrypted with a KMS key. You can't share AMIs that are backed by snapshots that are encrypted with the default AWS managed key. For more information, see [Share an Amazon EBS snapshot \(p. 1810\)](#).
 - If you share an AMI that is backed by encrypted snapshots, you must allow the AWS accounts to use the KMS keys that were used to encrypt the snapshots. For more information, see [Allow organizations and OUs to use a KMS key \(p. 136\)](#). To set up the key policy that you need to launch Auto Scaling instances when you use a customer managed key for encryption, see [Required AWS KMS key policy for use with encrypted volumes](#) in the *Amazon EC2 Auto Scaling User Guide*.
- **Region** – AMIs are a Regional resource. When you share an AMI, it is only available in that Region. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see [Copy an AMI \(p. 166\)](#).
- **Usage** – When you share an AMI, users can only launch instances from the AMI. They can't delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from their instance.
- **Copying shared AMIs** – If users in another account want to copy a shared AMI, you must grant them read permissions for the storage that backs the AMI. For more information, see [Cross-account copying \(p. 171\)](#).
- **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

Share an AMI (console)

New console

To grant explicit launch permissions using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions, Edit AMI permissions**.
4. Choose **Private**.
5. Under **Shared accounts**, choose **Add account ID**.
6. For **AWS account ID**, enter the AWS account ID with which you want to share the AMI, and then choose **Share AMI**.

To share this AMI with multiple accounts, repeat Steps 5 and 6 until you have added all the required account IDs.

Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch.

However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see [Share an Amazon EBS snapshot \(p. 1810\)](#).

7. Choose **Save changes** when you are done.
8. (Optional) To view the AWS account IDs with which you have shared the AMI, select the AMI in the list, and choose the **Permissions** tab. To find AMIs that are shared with you, see [Find shared AMIs \(p. 129\)](#).

Old console

To grant explicit launch permissions using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions, Modify Image Permissions**.
4. Specify the AWS account ID of the user with whom you want to share the AMI in the **AWS Account Number** field, then choose **Add Permission**.

To share this AMI with multiple users, repeat this step until you have added all the required users.

Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see [Share an Amazon EBS snapshot \(p. 1810\)](#).

5. Choose **Save** when you are done.
6. (Optional) To view the AWS account IDs with which you have shared the AMI, select the AMI in the list, and choose the **Permissions** tab. To find AMIs that are shared with you, see [Find shared AMIs \(p. 129\)](#).

Share an AMI (Tools for Windows PowerShell)

Use the [Edit-EC2ImageAttribute](#) command (Tools for Windows PowerShell) to share an AMI as shown in the following examples.

To grant explicit launch permissions

The following command grants launch permissions for the specified AMI to the specified AWS account. In the following example, replace the example AMI ID with a valid AMI ID, and replace `account-id` with the 12-digit AWS account ID.

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission -OperationType add -UserId "account-id"
```

Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see [Share an Amazon EBS snapshot \(p. 1810\)](#).

To remove launch permissions for an account

The following command removes launch permissions for the specified AMI from the specified AWS account. In the following example, replace the example AMI ID with a valid AMI ID, and replace *account-id* with the 12-digit AWS account ID.

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission -OperationType remove -UserId "account-id"
```

To remove all launch permissions

The following command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command. In the following example, replace the example AMI ID with a valid AMI ID.

```
PS C:\> Reset-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission
```

Share an AMI (AWS CLI)

Use the [modify-image-attribute](#) command (AWS CLI) to share an AMI as shown in the following examples.

To grant explicit launch permissions

The following command grants launch permissions for the specified AMI to the specified AWS account. In the following example, replace the example AMI ID with a valid AMI ID, and replace *account-id* with the 12-digit AWS account ID.

```
aws ec2 modify-image-attribute \  
  --image-id ami-0abcdef1234567890 \  
  --launch-permission "Add=[{UserId=account-id}]"
```

Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see [Share an Amazon EBS snapshot \(p. 1810\)](#).

To remove launch permissions for an account

The following command removes launch permissions for the specified AMI from the specified AWS account. In the following example, replace the example AMI ID with a valid AMI ID, and replace *account-id* with the 12-digit AWS account ID.

```
aws ec2 modify-image-attribute \  
  --image-id ami-0abcdef1234567890 \  
  --launch-permission "Remove=[{UserId=account-id}]"
```

To remove all launch permissions

The following command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command. In the following example, replace the example AMI ID with a valid AMI ID.

```
aws ec2 reset-image-attribute \  
  --image-id ami-0abcdef1234567890 \  
  --attribute launchPermission
```

Cancel having an AMI shared with your AWS account

An Amazon Machine Image (AMI) can be [shared with specific AWS accounts \(p. 141\)](#) by adding the accounts to the AMI's launch permissions. If an AMI has been shared with your AWS account and you no longer want it shared with your account, you can remove your account from the AMI's launch permissions. You do this by running the `cancel-image-launch-permission` AWS CLI command. When running this command, your AWS account is removed from the launch permissions for the specified AMI.

You might cancel having an AMI shared with your account, for example, to reduce the likelihood of launching an instance with an unused or deprecated AMI that was shared with you. When you cancel having an AMI shared with your account, it no longer appears in any AMI lists in the EC2 console or in the output for [describe-images](#).

Topics

- [Limitations \(p. 145\)](#)
- [Cancel having an AMI shared with your account \(p. 145\)](#)
- [Find AMIs that are shared with your account \(p. 146\)](#)

Limitations

- You can remove your account from the launch permissions of an AMI that is shared with your AWS account only. You can't use `cancel-image-launch-permission` to remove your account from the launch permissions of an [AMI shared with an organization or organizational unit \(OU\) \(p. 134\)](#) or to remove access to public AMIs.
- You can't permanently remove your account from the launch permissions of an AMI. An AMI owner can share an AMI with your account again.
- AMIs are a Regional resource. When running `cancel-image-launch-permission`, you must specify the Region in which the AMI is located. Either specify the Region in the command, or use the [AWS_DEFAULT_REGION environment variable](#).
- Only the AWS CLI and SDKs support removing your account from the launch permissions of an AMI. The EC2 console does not currently support this action.

Cancel having an AMI shared with your account

Note

After you cancel having an AMI shared with your account, you can't undo it. To regain access to the AMI, the AMI owner must share it with your account.

AWS CLI

To cancel having an AMI shared with your AWS account

Use the [cancel-image-launch-permission](#) command and specify the AMI ID.

```
aws ec2 cancel-image-launch-permission \
    --image-id ami-0123456789example \
    --region us-east-1
```

Expected output

```
{  
    "Return": true
```

}

PowerShell

To cancel having an AMI shared with your AWS account using the AWS Tools for PowerShell

Use the [Stop-EC2ImageLaunchPermission](#) command and specify the AMI ID.

```
Stop-EC2ImageLaunchPermission  
  -ImageId ami-0123456789example  
  -Region us-east-1
```

Expected output

```
True
```

Find AMIs that are shared with your account

To find the AMIs that are shared with your AWS account, see [Find shared AMIs \(p. 129\)](#).

Use bookmarks

If you have created a public AMI, or shared an AMI with another AWS account, you can create a *bookmark* that allows a user to access your AMI and launch an instance in their own account immediately. This is an easy way to share AMI references, so users don't have to spend time finding your AMI in order to use it.

Note that your AMI must be public, or you must have shared it with the user to whom you want to send the bookmark.

To create a bookmark for your AMI

1. Type a URL with the following information, where *region* is the Region in which your AMI resides:

```
https://console.aws.amazon.com/ec2/v2/home?  
region=region#LaunchInstanceWizard:ami=ami\_id
```

For example, this URL launches an instance from the ami-0abcdef1234567890 AMI in the US East (N. Virginia) us-east-1 Region:

```
https://console.aws.amazon.com/ec2/v2/home?  
region=us-east-1#LaunchInstanceWizard:ami=ami-0abcdef1234567890
```

2. Distribute the link to users who want to use your AMI.
3. To use a bookmark, choose the link or copy and paste it into your browser. The launch wizard opens, with the AMI already selected.

Best practices for shared Windows AMIs

Use the following guidelines to reduce the attack surface and improve the reliability of the AMIs you create.

- No list of security guidelines can be exhaustive. Build your shared AMIs carefully and take time to consider where you might expose sensitive data.

- Develop a repeatable process for building, updating, and republishing AMIs.
- Build AMIs using the most up-to-date operating systems, packages, and software.
- [Download](#) and install the latest version of the EC2Config service. For more information about installing this service, see [Install the latest version of EC2Config \(p. 755\)](#).
- Verify that Ec2SetPassword, Ec2WindowsActivate and Ec2HandleUserData are enabled.
- Verify that no guest accounts or Remote Desktop user accounts are present.
- Disable or remove unnecessary services and programs to reduce the attack surface of your AMI.
- Remove instance credentials, such as your key pair, from the AMI (if you saved them on the AMI). Store the credentials in a safe location.
- Ensure that the administrator password and passwords on any other accounts are set to an appropriate value for sharing. These passwords are available for anyone who launches your shared AMI.
- Test your AMI before you share it.

Paid AMIs

After you create an AMI, you can keep it private so that only you can use it, or you can share it with a specified list of AWS accounts. You can also make your custom AMI public so that the community can use it. Building a safe, secure, usable AMI for public consumption is a fairly straightforward process, if you follow a few simple guidelines. For information about how to create and use shared AMIs, see [Shared AMIs \(p. 129\)](#).

You can purchase AMIs from a third party, including AMIs that come with service contracts from organizations such as Red Hat. You can also create an AMI and sell it to other Amazon EC2 users.

A *paid AMI* is an AMI that you can purchase from a developer.

Amazon EC2 integrates with AWS Marketplace, enabling developers to charge other Amazon EC2 users for the use of their AMIs or to provide support for instances.

The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs that you can use to launch your EC2 instance. The AWS Marketplace AMIs are organized into categories, such as Developer Tools, to enable you to find products to suit your requirements. For more information about AWS Marketplace, see the [AWS Marketplace](#) website.

Launching an instance from a paid AMI is the same as launching an instance from any other AMI. No additional parameters are required. The instance is charged according to the rates set by the owner of the AMI, as well as the standard usage fees for the related web services, for example, the hourly rate for running an m1.small instance type in Amazon EC2. Additional taxes might also apply. The owner of the paid AMI can confirm whether a specific instance was launched using that paid AMI.

Important

Amazon DevPay is no longer accepting new sellers or products. AWS Marketplace is now the single, unified e-commerce platform for selling software and services through AWS. For information about how to deploy and sell software from AWS Marketplace, see [Selling in AWS Marketplace](#). AWS Marketplace supports AMIs backed by Amazon EBS.

Contents

- [Sell your AMI \(p. 148\)](#)
- [Find a paid AMI \(p. 148\)](#)
- [Purchase a paid AMI \(p. 149\)](#)
- [Get the product code for your instance \(p. 149\)](#)
- [Use paid support \(p. 150\)](#)
- [Bills for paid and supported AMIs \(p. 150\)](#)
- [Manage your AWS Marketplace subscriptions \(p. 150\)](#)

Sell your AMI

You can sell your AMI using AWS Marketplace. AWS Marketplace offers an organized shopping experience. Additionally, AWS Marketplace also supports AWS features such as Amazon EBS-backed AMIs, Reserved Instances, and Spot Instances.

For information about how to sell your AMI on the AWS Marketplace, see [Selling in AWS Marketplace](#).

Find a paid AMI

There are several ways that you can find AMIs that are available for you to purchase. For example, you can use [AWS Marketplace](#), the Amazon EC2 console, or the command line. Alternatively, a developer might let you know about a paid AMI themselves.

Find a paid AMI using the console

To find a paid AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**.
3. Choose **Public images** for the first filter.
4. In the Search bar, choose **Owner alias**, then =, and then **aws-marketplace**.
5. If you know the product code, choose **Product code**, then =, and then enter the product code.

Find a paid AMI using AWS Marketplace

To find a paid AMI using AWS Marketplace

1. Open [AWS Marketplace](#).
2. Enter the name of the operating system in the search field, and then choose the search button (magnifying glass).
3. To scope the results further, use one of the categories or filters.
4. Each product is labeled with its product type: either AMI or Software as a Service.

Find a paid AMI using the Tools for Windows PowerShell

You can find a paid AMI using the following [Get-EC2Image](#) command.

```
PS C:\> Get-EC2Image -Owner aws-marketplace
```

The output for a paid AMI includes the product code.

ProductCodeId	ProductCodeType
----- <i>product_code</i>	----- marketplace

If you know the product code, you can filter the results by product code. This example returns the most recent AMI with the specified product code.

```
PS C:\> (Get-EC2Image -Owner aws-marketplace -Filter @{"Name"="product-code"; "Value"="product_code"} | sort CreationDate -Descending | Select-Object -First 1).ImageId
```

Find a paid AMI using the AWS CLI

You can find a paid AMI using the following [describe-images](#) command (AWS CLI).

```
aws ec2 describe-images
--owners aws-marketplace
```

This command returns numerous details that describe each AMI, including the product code for a paid AMI. The output from `describe-images` includes an entry for the product code like the following:

```
"ProductCodes": [
{
    "ProductCodeId": "product_code",
    "ProductCodeType": "marketplace"
},
],
```

If you know the product code, you can filter the results by product code. This example returns the most recent AMI with the specified product code.

```
aws ec2 describe-images
--owners aws-marketplace \
--filters "Name=product-code,Values=product_code" \
--query "sort_by(Images, &CreationDate)[-1].[ImageId]"
```

Purchase a paid AMI

You must sign up for (purchase) a paid AMI before you can launch an instance using the AMI.

Typically a seller of a paid AMI presents you with information about the AMI, including its price and a link where you can buy it. When you click the link, you're first asked to log into AWS, and then you can purchase the AMI.

Purchase a paid AMI using the console

You can purchase a paid AMI by using the Amazon EC2 launch wizard. For more information, see [Launch an AWS Marketplace instance \(p. 592\)](#).

Subscribe to a product using AWS Marketplace

To use the AWS Marketplace, you must have an AWS account. To launch instances from AWS Marketplace products, you must be signed up to use the Amazon EC2 service, and you must be subscribed to the product from which to launch the instance. There are two ways to subscribe to products in the AWS Marketplace:

- **AWS Marketplace website:** You can launch preconfigured software quickly with the 1-Click deployment feature.
- **Amazon EC2 launch wizard:** You can search for an AMI and launch an instance directly from the wizard. For more information, see [Launch an AWS Marketplace instance \(p. 592\)](#).

Get the product code for your instance

You can retrieve the AWS Marketplace product code for your instance using its instance metadata. For more information about retrieving metadata, see [Instance metadata and user data \(p. 862\)](#).

To retrieve a product code, use the following command:

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/product-codes
```

If the instance has a product code, Amazon EC2 returns it.

Use paid support

Amazon EC2 also enables developers to offer support for software (or derived AMIs). Developers can create support products that you can sign up to use. During sign-up for the support product, the developer gives you a product code, which you must then associate with your own AMI. This enables the developer to confirm that your instance is eligible for support. It also ensures that when you run instances of the product, you are charged according to the terms for the product specified by the developer.

Important

You can't use a support product with Reserved Instances. You always pay the price that's specified by the seller of the support product.

To associate a product code with your AMI, use one of the following commands, where *ami_id* is the ID of the AMI and *product_code* is the product code:

- [modify-image-attribute](#) (AWS CLI)

```
aws ec2 modify-image-attribute --image-id ami_id --product-codes "product_code"
```

- [Edit-EC2ImageAttribute](#) (AWS Tools for Windows PowerShell)

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami_id -ProductCode product_code
```

After you set the product code attribute, it cannot be changed or removed.

Bills for paid and supported AMIs

At the end of each month, you receive an email with the amount your credit card has been charged for using any paid or supported AMIs during the month. This bill is separate from your regular Amazon EC2 bill. For more information, see [Paying for products](#) in the *AWS Marketplace Buyer Guide*.

Manage your AWS Marketplace subscriptions

On the AWS Marketplace website, you can check your subscription details, view the vendor's usage instructions, manage your subscriptions, and more.

To check your subscription details

1. Log in to the [AWS Marketplace](#).
2. Choose Your Marketplace Account.
3. Choose Manage your software subscriptions.
4. All your current subscriptions are listed. Choose **Usage Instructions** to view specific instructions for using the product, for example, a user name for connecting to your running instance.

To cancel an AWS Marketplace subscription

1. Ensure that you have terminated any instances running from the subscription.

- a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
 - b. In the navigation pane, choose **Instances**.
 - c. Select the instance, and then choose **Instance state, Terminate instance**.
 - d. Choose **Terminate** when prompted for confirmation.
2. Log in to the [AWS Marketplace](#), and choose **Your Marketplace Account**, then **Manage your software subscriptions**.
 3. Choose **Cancel subscription**. You are prompted to confirm your cancellation.

Note

After you've canceled your subscription, you are no longer able to launch any instances from that AMI. To use that AMI again, you need to resubscribe to it, either on the AWS Marketplace website, or through the launch wizard in the Amazon EC2 console.

AMI lifecycle

You can create your own AMIs, copy them, back them up, and maintain them until you are ready to deprecate or deregister them.

Contents

- [Create a custom Windows AMI \(p. 151\)](#)
- [Modify an AMI \(p. 166\)](#)
- [Copy an AMI \(p. 166\)](#)
- [Store and restore an AMI using S3 \(p. 173\)](#)
- [Deprecate an AMI \(p. 179\)](#)
- [Deregister your AMI \(p. 185\)](#)
- [Recover AMIs from the Recycle Bin \(p. 189\)](#)
- [Automate the EBS-backed AMI lifecycle \(p. 193\)](#)

Create a custom Windows AMI

You can launch an instance from an existing Windows AMI, customize the instance, and then save this updated configuration as a custom AMI. Instances launched from this new custom AMI include the customizations that you made when you created the AMI.

To help categorize and manage your AMIs, you can assign custom *tags* to them. For more information, see [Tag your Amazon EC2 resources \(p. 2085\)](#).

To create a custom Linux AMI, use the procedure for the type of volume for the instance. For more information, see [Create an Amazon EBS-backed Linux AMI](#) or [Create an instance store-backed Linux AMI](#) in the *Amazon EC2 User Guide for Linux Instances*.

Topics

- [How the creation of a custom AMI works \(p. 151\)](#)
- [Create a Windows AMI from a running instance \(p. 152\)](#)
- [Create a standardized Amazon Machine Image \(AMI\) using Sysprep \(p. 154\)](#)

How the creation of a custom AMI works

First, launch an instance from an AMI that's similar to the AMI that you'd like to create. You can connect to your instance and customize it. When the instance is set up the way you want it, ensure data integrity

by stopping the instance before you create an AMI and then create the image. We automatically register the AMI for you.

During the AMI-creation process, Amazon EC2 creates snapshots of your instance's root volume and any other EBS volumes attached to your instance. You're charged for the snapshots until you deregister the AMI and delete the snapshots. For more information, see [Deregister your AMI \(p. 185\)](#). If any volumes attached to the instance are encrypted, the new AMI only launches successfully on instance types that support Amazon EBS encryption. For more information, see [Amazon EBS encryption \(p. 1921\)](#).

Depending on the size of the volumes, it can take several minutes for the AMI-creation process to complete (sometimes up to 24 hours). You may find it more efficient to create snapshots of your volumes prior to creating your AMI. This way, only small, incremental snapshots need to be created when the AMI is created, and the process completes more quickly (the total time for snapshot creation remains the same). For more information, see [Create Amazon EBS snapshots \(p. 1762\)](#).

After the process completes, you have a new AMI and snapshot created from the root volume of the instance. When you launch an instance using the new AMI, we create a new EBS volume for its root volume using the snapshot.

Note

A Windows AMI must be created from an Amazon EC2 instance. Creation of a Windows AMI from an EBS snapshot is currently not supported as it might cause issues with billing, performance, and general operation.

If you add instance store volumes or Amazon Elastic Block Store (Amazon EBS) volumes to your instance in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI automatically contain information for these volumes. The instance store volumes specified in the block device mapping for the new instance are new and don't contain any data from the instance store volumes of the instance you used to create the AMI. The data on EBS volumes persists. For more information, see [Block device mappings \(p. 2026\)](#).

Note

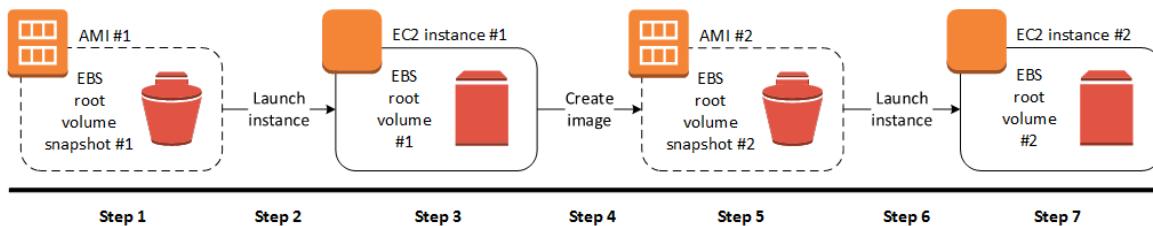

When you create a new instance from a custom AMI, you should initialize both its root volume and any additional EBS storage before putting it into production. For more information, see [Initialize Amazon EBS volumes](#).

Create a Windows AMI from a running instance

You can create an AMI using the AWS Management Console or the command line. The following diagram summarizes the process for creating an AMI from a running EC2 instance. Start with an existing AMI, launch an instance, customize it, create a new AMI from it, and finally launch an instance of your new AMI. The steps in the following diagram match the steps in the procedure below.

Note

If you already have a running Windows instance, you can go directly to step 5.

To create an AMI from an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, under **Images**, choose **AMIs**.

3. Use the **Filter** options to scope the list of AMIs to the Windows AMIs that meet your needs. For example, to view the Windows AMIs provided by AWS, choose **Public images** from the drop-down list. Choose the Search bar, and then from the menu, choose **Owner alias**, then **=**, and then **amazon**. Choose **Source** from the menu and enter one of the following, depending on the version of Windows Server that you need:

- **amazon/Windows_Server-2022**
- **amazon/Windows_Server-2019**
- **amazon/Windows_Server-2016**
- **amazon/Windows_Server-2012**

Add any other filters that you need. When you have chosen an AMI, select its check box.

4. Choose **Launch instance from AMI** (new console) or **Launch** (old console). Accept the default values as you step through the wizard. For more information, see [Launch an instance using the new launch instance wizard \(p. 552\)](#). When the instance is ready, connect to it. For more information, see [Connect to your Windows instance \(p. 626\)](#).
5. Once you connect to the instance, you can perform any of the following actions to customize it for your needs:

- Install software and applications
- Copy data
- Reduce start time by deleting temporary files and defragmenting your hard drive
- Attach additional EBS volumes
- Create a new user account and add it to the Administrators group

If you are sharing your AMI, these credentials can be supplied for RDP access without disclosing your default administrator password.

- [Windows Server 2022 and later] Configure settings using EC2Launch v2. To generate a random password at launch time, configure the `setAdminAccount` task. For more information, see [setAdminAccount \(p. 726\)](#).
- [Windows Server 2016 and 2019] Configure settings using EC2Launch. To generate a random password at launch time, use the `adminPasswordType` setting. For more information, see [Configure EC2Launch \(p. 746\)](#).
- [Windows Server 2012 R2 and earlier] Configure settings using EC2Config. To generate a random password at launch time, enable the `Ec2SetPassword` plugin; otherwise, the current administrator password is used. For more information, see [EC2Config settings files \(p. 760\)](#).
- [Windows Server 2008 R2] If the instance uses RedHat drivers to access Xen virtualized hardware, upgrade to Citrix drivers before you create an AMI. For more information, see [Upgrade Windows Server 2008 and 2008 R2 instances \(Redhat to Citrix PV upgrade\) \(p. 789\)](#).

6. In the navigation pane, choose **Instances** and select your instance. Choose **Actions, Image and templates**, and **Create image**.

Tip

If this option is disabled, your instance isn't an Amazon EBS-backed instance.

7. Specify a unique name for the image and an optional description (up to 255 characters).

By default, when Amazon EC2 creates the new AMI, it reboots the instance so that it can take snapshots of the attached volumes while data is at rest, in order to ensure a consistent state. For the **No reboot** setting, you can select the **Enable** check box to prevent Amazon EC2 from shutting down and rebooting the instance.

Warning

If you choose to enable **No reboot**, we can't guarantee the file system integrity of the created image.

(Optional) Modify the root volume, EBS volumes, and instance store volumes as needed. For example:

- To change the size of the root volume, locate the **Root** volume in the **Type** column, and fill in the **Size** field.
- To suppress an EBS volume specified by the block device mapping of the AMI used to launch the instance, locate the EBS volume in the list and choose **Delete**.
- To add an EBS volume, choose **Add New Volume**, **Type**, and **EBS**, and fill in the fields. When you then launch an instance from your new AMI, these additional volumes are automatically attached to the instance. Empty volumes must be formatted and mounted. Volumes based on a snapshot must be mounted.
- To suppress an instance store volume specified by the block device mapping of the AMI used to launch the instance, locate the volume in the list and choose **Delete**.
- To add an instance store volume, choose **Add New Volume**, **Type**, and **Instance Store**, and select a device name from the **Device** list. When you launch an instance from your new AMI, these additional volumes are automatically initialized and mounted. These volumes don't contain data from the instance store volumes of the running instance from which you based your AMI.

When you are finished, choose **Create Image**.

8. While your AMI is being created, you can choose **AMIs** in the navigation pane to view its status. Clear your previous filters, and choose **Owned by me** from the drop-down list. Initially, the status is pending. After a few minutes, the status should change to available.

(Optional) Choose **Snapshots** in the navigation pane to view the snapshot that was created for the new AMI. When you launch an instance from this AMI, we use this snapshot to create its root device volume.

9. Launch an instance from your new AMI. For more information, see [Launch an instance using the new launch instance wizard \(p. 552\)](#). The new running instance contains all of the customizations you applied in previous steps, and any additional customization you add when launching the instance, such as user data (scripts that run when the instance starts).

Create an AMI from an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [create-image](#) (AWS CLI)
- [New-EC2Image](#) (AWS Tools for Windows PowerShell)

Create a standardized Amazon Machine Image (AMI) using Sysprep

The Microsoft System Preparation (Sysprep) tool simplifies the process of duplicating a customized installation of Windows. You can use Sysprep to create a standardized Amazon Machine Image (AMI). You can then create new Amazon EC2 instances for Windows from this standardized image.

We recommend that you use [EC2 Image Builder](#) to automate the creation, management, and deployment of customized, secure, and up-to-date "golden" server images that are pre-installed and preconfigured with software and settings.

If you use Sysprep to create a standardized AMI, we recommend that you run Sysprep with [EC2Launch v2 \(p. 692\)](#). If you are still using the EC2Config (Windows Server 2012 R2 and earlier) or EC2Launch

(Windows Server 2016 and 2019) agents, see the documentation for using Sysprep with EC2Config and EC2Launch below.

Important

Do not use Sysprep to create an instance backup. Sysprep removes system-specific information; removing this information might have unintended consequences for an instance backup.

To troubleshoot Sysprep, see [Troubleshoot Sysprep \(p. 2149\)](#).

Contents

- [Before you begin \(p. 155\)](#)
- [Use Sysprep with EC2Launch v2 \(p. 155\)](#)
- [Use Sysprep with EC2Launch \(p. 158\)](#)
- [Use Sysprep with EC2Config \(p. 162\)](#)

Before you begin

- Before performing Sysprep, we recommend that you remove all local user accounts and all account profiles other than a single administrator account under which Sysprep will be run. If you perform Sysprep with additional accounts and profiles, unexpected behavior could result, including loss of profile data or failure to complete Sysprep.
- Learn more about [Sysprep](#) on Microsoft TechNet.
- Learn which [server roles are supported for Sysprep](#).

Use Sysprep with EC2Launch v2

This section contains details about the different Sysprep execution phases and the tasks performed by the EC2Launch v2 service as the image is prepared. It also includes the steps to create a standardized AMI using Sysprep with the EC2Launch v2 service.

Sysprep with EC2Launch v2 topics

- [Sysprep phases \(p. 155\)](#)
- [Sysprep actions \(p. 156\)](#)
- [Post Sysprep \(p. 157\)](#)
- [Run Sysprep with EC2Launch v2 \(p. 158\)](#)

Sysprep phases

Sysprep runs through the following phases:

- **Generalize:** The tool removes image-specific information and configurations. For example, Sysprep removes the security identifier (SID), the computer name, the event logs, and specific drivers, to name a few. After this phase is completed, the operating system (OS) is ready to create an AMI.

Note

When you run Sysprep with the EC2Launch v2 service, the system prevents drivers from being removed because the PersistAllDeviceInstalls setting is set to true by default.

- **Specialize:** Plug and Play scans the computer and installs drivers for any detected devices. The tool generates OS requirements, like the computer name and SID. Optionally, you can run commands in this phase.
- **Out-of-Box Experience (OOBE):** The system runs an abbreviated version of Windows Setup and asks you to enter information such as system language, time zone, and registered organization. When you run Sysprep with EC2Launch v2, the answer file automates this phase.

Sysprep actions

Sysprep and EC2Launch v2 perform the following actions when preparing an image.

1. When you choose **Shutdown with Sysprep** in the **EC2Launch settings** dialog box, the system runs the `ec2launch sysprep` command.
2. EC2Launch v2 edits the content of the `unattend.xml` file by reading the registry value at `HKEY_USERS\.DEFAULT\Control Panel\International\LocaleName`. This file is located in the following directory: `C:\ProgramData\Amazon\EC2Launch\sysprep`.
3. The system run the `BeforeSysprep.cmd`. This command creates a registry key as follows:

```
reg add "HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Terminal Server" /v fDenyTSConnections /t REG_DWORD /d 1 /f
```

The registry key disables RDP connections until they are re-enabled. Disabling RDP connections is a necessary security measure because, during the first boot session after Sysprep has run, there is a short period of time where RDP allows connections and the Administrator password is blank.

4. The EC2Launch v2 service calls Sysprep by running the following command:

```
sysprep.exe /oobe /generalize /shutdown /unattend: "C:\ProgramData\Amazon\EC2Launch\sysprep\unattend.xml"
```

Generalize phase

- EC2Launch v2 removes image-specific information and configurations, such as the computer name and the SID. If the instance is a member of a domain, it is removed from the domain. The `unattend.xml` answer file includes the following settings that affect this phase:
 - **PersistAllDeviceInstalls**: This setting prevents Windows Setup from removing and reconfiguring devices, which speeds up the image preparation process because Amazon AMIs require certain drivers to run and re-detection of those drivers would take time.
 - **DoNotCleanUpNonPresentDevices**: This setting retains Plug and Play information for devices that are not currently present.
- Sysprep shuts down the OS as it prepares to create the AMI. The system either launches a new instance or starts the original instance.

Specialize phase

The system generates OS-specific requirements, such as a computer name and an SID. The system also performs the following actions based on configurations that you specify in the `unattend.xml` answer file.

- **CopyProfile**: Sysprep can be configured to delete all user profiles, including the built-in Administrator profile. This setting retains the built-in Administrator account so that any customizations you make to that account are carried over to the new image. The default value is True.

CopyProfile replaces the default profile with the existing local administrator profile. All accounts that you log in to after running Sysprep receive a copy of that profile and its contents at first login.

If you don't have specific user-profile customizations that you want to carry over to the new image, then change this setting to False. Sysprep will remove all user profiles (this saves time and disk space).

- **TimeZone**: The time zone is set to Coordinate Universal Time (UTC) by default.
- **Synchronous command with order 1**: The system runs the following command, which enables the administrator account and specifies the password requirement:

```
net user Administrator /ACTIVE:YES /LOGONPASSWORDCHG:NO /EXPIRES:NEVER /  
PASSWORDREQ:YES
```

- **Synchronous command with order 2:** The system scrambles the administrator password. This security measure is designed to prevent the instance from being accessible after Sysprep completes if you did not enable the ec2setpassword setting.

C:\Program Files\Amazon\Ec2ConfigService\ScramblePassword.exe" -u Administrator

- **Synchronous command with order 3:** The system runs the following command:

C:\Program Files\Amazon\Ec2ConfigService\Scripts\SysprepSpecializePhase.cmd

This command adds the following registry key, which re-enables RDP:

```
reg add "HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Terminal Server" /v  
fDenyTSConnections /t REG_DWORD /d 0 /f
```

OOBE phase

1. The system specifies the following configurations using the EC2Launch v2 answer file:

- <InputLocale>en-US</InputLocale>
- <SystemLocale>en-US</SystemLocale>
- <UILanguage>en-US</UILanguage>
- <UserLocale>en-US</UserLocale>
- <HideEULAPage>true</HideEULAPage>
- <HideWirelessSetupInOOBE>true</HideWirelessSetupInOOBE>
- <ProtectYourPC>3</ProtectYourPC>
- <BluetoothTaskbarIconEnabled>false</BluetoothTaskbarIconEnabled>
- <TimeZone>UTC</TimeZone>
- <RegisteredOrganization>Amazon.com</RegisteredOrganization>
- <RegisteredOwner>EC2</RegisteredOwner>

Note

During the generalize and specialize phases, EC2Launch v2 monitors the status of the OS. If EC2Launch v2 detects that the OS is in a Sysprep phase, then it publishes the following message to the system log:

Windows is being configured. SysprepState=IMAGE_STATE_UNDEPLOYABLE

2. The system runs EC2Launch v2.

Post Sysprep

After Sysprep completes, EC2Launch v2 sends the following message to the console output:

```
Windows sysprep configuration complete.
```

EC2Launch v2 then performs the following actions:

1. Reads the content of the agent-config.yml file and runs configured tasks.
2. Executes all tasks in the preReady stage.
3. After it is finished, sends a Windows is ready message to the instance system logs.
4. Executes all tasks in the PostReady stage.

For more information about EC2Launch v2 , see [Configure a Windows instance using EC2Launch v2 \(p. 692\)](#).

Run Sysprep with EC2Launch v2

Use the following procedure to create a standardized AMI using Sysprep with EC2Launch v2.

1. In the Amazon EC2 console, locate or [create \(p. 151\)](#) an AMI that you want to duplicate.
2. Launch and connect to your Windows instance.
3. Customize it.
4. From the Windows **Start** menu, search for and choose **Amazon EC2Launch settings**. For more information about the options and settings in the Amazon EC2Launch settings dialog box, see [EC2Launch v2 settings \(p. 703\)](#).
5. Select **Shutdown with Sysprep** or **Shutdown without Sysprep**.

When you are asked to confirm that you want to run Sysprep and shut down the instance, click **Yes**. EC2Launch v2 runs Sysprep. Next, you are logged off the instance, and the instance shuts down. If you check the **Instances** page in the Amazon EC2 console, the instance state changes from Running to Stopping to Stopped. At this point, it's safe to create an AMI from this instance.

You can manually invoke the Sysprep tool from the command line using the following command:

```
"%programfiles%\amazon\ec2launch\ec2launch.exe" sysprep --shutdown=true
```

Use Sysprep with EC2Launch

EC2Launch offers a default answer file and batch files for Sysprep that automate and secure the image-preparation process on your AMI. Modifying these files is optional. These files are located in the following directory by default: C:\ProgramData\Amazon\EC2-Windows\Launch\Sysprep.

Important

Do not use Sysprep to create an instance backup. Sysprep removes system-specific information. If you remove this information there might be unintended consequences for an instance backup.

Sysprep with EC2Launch topics

- [EC2Launch answer and batch files for Sysprep \(p. 158\)](#)
- [Run Sysprep with EC2Launch \(p. 159\)](#)
- [Update metadata/KMS routes for Server 2016 and later when launching a custom AMI \(p. 162\)](#)

EC2Launch answer and batch files for Sysprep

The EC2Launch answer file and batch files for Sysprep include the following:

Unattend.xml

This is the default answer file. If you run SysprepInstance.ps1 or choose **ShutdownWithSysprep** in the user interface, the system reads the setting from this file.

BeforeSysprep.cmd

Customize this batch file to run commands before EC2Launch runs Sysprep.

SysprepSpecialize.cmd

Customize this batch file to run commands during the Sysprep specialize phase.

Run Sysprep with EC2Launch

On the full installation of Windows Server 2016 and later (with a desktop experience), you can run Sysprep with EC2Launch manually or by using the **EC2 Launch Settings** application.

To run Sysprep using the EC2Launch Settings application

1. In the Amazon EC2 console, locate or create a Windows Server 2016 or later AMI.
2. Launch a Windows instance from the AMI.
3. Connect to your Windows instance and customize it.
4. Search for and run the **EC2LaunchSettings** application. It is located in the following directory by default: C:\ProgramData\Amazon\EC2-Windows\Launch\Settings.

 Ec2 Launch Settings X

General

Set Computer Name

Set the computer name of the instance ip-<hex internal IP>. Disable this feature to persist your own computer name setting.

Set Wallpaper

Overlay instance information on the current wallpaper.

Extend Boot Volume

Extend OS partition to consume free space for boot volume.

Add DNS Suffix List

Add DNS suffix list to allow DNS resolution of servers running in EC2 without providing the fully qualified domain name.

Handle User Data

Execute user data provided at instance launch.
Note: This will be re-enabled when running shutdown with sysprep below.

Administrator Password

Random (Retrieve from console)

Specify (Temporarily store in config file)

Do Nothing (Customize Unattend.xml for sysprep)

These changes will take effect on next boot if Ec2Launch script is scheduled. By default, it is scheduled by shutdown options below.

Sysprep

Sysprep is a Microsoft tool that prepares an image for multiple launches.

Ec2Launch Script Location: [Found](#)

Run EC2Launch on every boot (instead of just the next boot).

Shutdown without Sysprep ¹⁶⁰ Shutdown with Sysprep

5. Select or clear options as needed. These settings are stored in the `LaunchConfig.json` file.
6. For **Administrator Password**, do one of the following:
 - Choose **Random**. EC2Launch generates a password and encrypts it using the user's key. The system disables this setting after the instance is launched so that this password persists if the instance is rebooted or stopped and started.
 - Choose **Specify** and type a password that meets the system requirements. The password is stored in `LaunchConfig.json` as clear text and is deleted after Sysprep sets the administrator password. If you shut down now, the password is set immediately. EC2Launch encrypts the password using the user's key.
 - Choose **DoNothing** and specify a password in the `unattend.xml` file. If you don't specify a password in `unattend.xml`, the administrator account is disabled.
7. Choose **Shutdown with Sysprep**.

To manually run Sysprep using EC2Launch

1. In the Amazon EC2 console locate or create a Windows Server 2016 or later Datacenter edition AMI that you want to duplicate.
2. Launch and connect to your Windows instance.
3. Customize the instance.
4. Specify settings in the `LaunchConfig.json` file. This file is located in the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config` directory by default.

For `adminPasswordType`, specify one of the following values:

Random

EC2Launch generates a password and encrypts it using the user's key. The system disables this setting after the instance is launched so that this password persists if the instance is rebooted or stopped and started.

Specify

EC2Launch uses the password you specify in `adminPassword`. If the password does not meet the system requirements, EC2Launch generates a random password instead. The password is stored in `LaunchConfig.json` as clear text and is deleted after Sysprep sets the administrator password. EC2Launch encrypts the password using the user's key.

DoNothing

EC2Launch uses the password you specify in the `unattend.xml` file. If you don't specify a password in `unattend.xml`, the administrator account is disabled.

5. (Optional) Specify settings in `unattend.xml` and other configuration files. If plan to attend to the installation, then you don't need to make changes in these files. The files are located in the following directory by default: `C:\ProgramData\Amazon\EC2-Windows\Launch\Sysprep`.
6. In Windows PowerShell, run `./InitializeInstance.ps1 -Schedule`. The script is located in the following directory, by default: `C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts`. This script schedules the instance to initialize during the next boot. You must run this script before you run the `SysprepInstance.ps1` script in the next step.
7. In Windows PowerShell, run `./SysprepInstance.ps1`. The script is located in the following directory by default: `C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts`.

You are logged off the instance and the instance shuts down. If you check the **Instances** page in the Amazon EC2 console, the instance state changes from Running to Stopping, and then to Stopped. At this point, it is safe to create an AMI from this instance.

Update metadata/KMS routes for Server 2016 and later when launching a custom AMI

To update metadata/KMS routes for Server 2016 and later when launching a custom AMI, do one of the following:

- Run the EC2LaunchSettings GUI (C:\ProgramData\Amazon\EC2-Windows\Launch\Settings\Ec2LaunchSettings.exe) and select the option to shut down with Sysprep.
- Run EC2LaunchSettings and shut down without Sysprep before creating the AMI. This sets the EC2 Launch Initialize tasks to run at the next boot, which will set routes based on the subnet for the instance.
- Manually reschedule EC2 Launch initialize tasks before creating an AMI from [PowerShell \(p. 747\)](#).

Important

Take note of the default password reset behavior before rescheduling tasks.

- To update the routes on a running instance that is experiencing Windows activation or communication with instance metadata failures, see ["Unable to activate Windows" \(p. 2112\)](#).

Use Sysprep with EC2Config

This section contains details about the different Sysprep execution phases and the tasks performed by the EC2Config service as the image is prepared. It also includes the steps to create a standardized AMI using Sysprep with the EC2Config service.

Sysprep with EC2Config topics

- [Sysprep phases \(p. 155\)](#)
- [Sysprep actions \(p. 162\)](#)
- [Post Sysprep \(p. 165\)](#)
- [Run Sysprep with the EC2Config service \(p. 165\)](#)

Sysprep phases

Sysprep runs through the following phases:

- **Generalize:** The tool removes image-specific information and configurations. For example, Sysprep removes the security identifier (SID), the computer name, the event logs, and specific drivers, to name a few. After this phase is completed, the operating system (OS) is ready to create an AMI.

Note

When you run Sysprep with the EC2Config service, the system prevents drivers from being removed because the PersistAllDeviceInstalls setting is set to true by default.

- **Specialize:** Plug and Play scans the computer and installs drivers for any detected devices. The tool generates OS requirements like the computer name and SID. Optionally, you can run commands in this phase.
- **Out-of-Box Experience (OOBE):** The system runs an abbreviated version of Windows Setup and asks the user to enter information such as a system language, the time zone, and a registered organization. When you run Sysprep with EC2Config, the answer file automates this phase.

Sysprep actions

Sysprep and the EC2Config service perform the following actions when preparing an image.

1. When you choose **Shutdown with Sysprep** in the **EC2 Service Properties** dialog box, the system runs the **ec2config.exe –sysprep** command.
2. The EC2Config service reads the content of the **BundleConfig.xml** file. This file is located in the following directory, by default: C:\Program Files\Amazon\Ec2ConfigService\Settings.

The `BundleConfig.xml` file includes the following settings. You can change these settings:

- **AutoSysprep:** Indicates whether to use Sysprep automatically. You do not need to change this value if you are running Sysprep from the EC2 Service Properties dialog box. The default value is No.
- **SetRDPCertificate:** Sets a self-signed certificate for the Remote Desktop server. This enables you to securely use the Remote Desktop Protocol (RDP) to connect to the instance. Change the value to Yes if new instances should use a certificate. This setting is not used with Windows Server 2008 or Windows Server 2012 instances because these operating systems can generate their own certificates. The default value is No.
- **SetPasswordAfterSysprep:** Sets a random password on a newly launched instance, encrypts it with the user launch key, and outputs the encrypted password to the console. Change the value to No if new instances should not be set to a random encrypted password. The default value is Yes.
- **PreSysprepRunCmd:** The location of the command to run. The command is located in the following directory, by default: `C:\Program Files\Amazon\Ec2ConfigService\Scripts\BeforeSysprep.cmd`

3. The system runs `BeforeSysprep.cmd`. This command creates a registry key as follows:

```
reg add "HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Terminal Server" /v fDenyTSConnections /t REG_DWORD /d 1 /f
```

The registry key disables RDP connections until they are re-enabled. Disabling RDP connections is a necessary security measure because, during the first boot session after Sysprep has run, there is a short period of time where RDP allows connections and the Administrator password is blank.

4. The EC2Config service calls Sysprep by running the following command:

```
sysprep.exe /unattend: "C:\Program Files\Amazon\Ec2ConfigService\sysprep2008.xml" /oobe /generalize /shutdown
```

Generalize phase

- The tool removes image-specific information and configurations such as the computer name and the SID. If the instance is a member of a domain, it is removed from the domain. The `sysprep2008.xml` answer file includes the following settings that affect this phase:
 - **PersistAllDeviceInstalls:** This setting prevents Windows Setup from removing and reconfiguring devices, which speeds up the image preparation process because Amazon AMIs require certain drivers to run and re-detection of those drivers would take time.
 - **DoNotCleanUpNonPresentDevices:** This setting retains Plug and Play information for devices that are not currently present.
- Sysprep shuts down the OS as it prepares to create the AMI. The system either launches a new instance or starts the original instance.

Specialize phase

The system generates OS specific requirements such as a computer name and a SID. The system also performs the following actions based on configurations that you specify in the `sysprep2008.xml` answer file.

- **CopyProfile:** Sysprep can be configured to delete all user profiles, including the built-in Administrator profile. This setting retains the built-in Administrator account so that any customizations you made to that account are carried over to the new image. The default value is True.

CopyProfile replaces the default profile with the existing local administrator profile. All accounts logged into after running Sysprep will receive a copy of that profile and its contents at first login.

If you don't have specific user-profile customizations that you want to carry over to the new image then change this setting to False. Sysprep will remove all user profiles; this saves time and disk space.

- **TimeZone:** The time zone is set to Coordinate Universal Time (UTC) by default.
- **Synchronous command with order 1:** The system runs the following command that enables the administrator account and specifies the password requirement.

```
net user Administrator /ACTIVE:YES /LOGONPASSWORDCHG:NO /EXPIRES:NEVER /  
PASSWORDREQ:YES
```

- **Synchronous command with order 2:** The system scrambles the administrator password. This security measure is designed to prevent the instance from being accessible after Sysprep completes if you did not enable the ec2setpassword setting.

```
C:\Program Files\Amazon\Ec2ConfigService\ScramblePassword.exe" -u Administrator
```

- **Synchronous command with order 3:** The system runs the following command:

```
C:\Program Files\Amazon\Ec2ConfigService\Scripts\SysprepSpecializePhase.cmd
```

This command adds the following registry key, which re-enables RDP:

```
reg add "HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Terminal Server" /v  
fDenyTSConnections /t REG_DWORD /d 0 /f
```

OOBE phase

1. Using the EC2Config service answer file, the system specifies the following configurations:

- <InputLocale>en-US</InputLocale>
- <SystemLocale>en-US</SystemLocale>
- <UILanguage>en-US</UILanguage>
- <UserLocale>en-US</UserLocale>
- <HideEULAPage>true</HideEULAPage>
- <HideWirelessSetupInOOBE>true</HideWirelessSetupInOOBE>
- <NetworkLocation>Other</NetworkLocation>
- <ProtectYourPC>3</ProtectYourPC>
- <BluetoothTaskbarIconEnabled>false</BluetoothTaskbarIconEnabled>
- <TimeZone>UTC</TimeZone>
- <RegisteredOrganization>Amazon.com</RegisteredOrganization>
- <RegisteredOwner>Amazon</RegisteredOwner>

Note

During the generalize and specialize phases the EC2Config service monitors the status of the OS. If EC2Config detects that the OS is in a Sysprep phase, then it publishes the following message to the system log:

EC2ConfigMonitorState: 0 Windows is being configured.

SysprepState=IMAGE_STATE_UNDEPLOYABLE

2. After the OOBE phase completes, the system runs SetupComplete.cmd from the following location: C:\Windows\Setup\Scripts\SetupComplete.cmd. In Amazon public AMIs before April 2015 this file was empty and ran nothing on the image. In public AMIs dated after April 2015, the file includes the following value: call "C:\Program Files\Amazon\Ec2ConfigService\Scripts\PostSysprep.cmd".
3. The system runs PostSysprep.cmd, which performs the following operations:
 - Sets the local Administrator password to not expire. If the password expired, Administrators might not be able to log on.
 - Sets the MSSQLServer machine name (if installed) so that the name will be in sync with the AMI.

Post Sysprep

After Sysprep completes, the EC2Config services sends the following message to the console output:

```
Windows sysprep configuration complete.  
Message: Sysprep Start  
Message: Sysprep End
```

EC2Config then performs the following actions:

1. Reads the content of the config.xml file and lists all enabled plug-ins.
2. Executes all "Before Windows is ready" plug-ins at the same time.
 - Ec2SetPassword
 - Ec2SetComputerName
 - Ec2InitializeDrives
 - Ec2EventLog
 - Ec2ConfigureRDP
 - Ec2OutputRDPCert
 - Ec2SetDriveLetter
 - Ec2WindowsActivate
 - Ec2DynamicBootVolumeSize
3. After it is finished, sends a "Windows is ready" message to the instance system logs.
4. Runs all "After Windows is ready" plug-ins at the same time.
 - Amazon CloudWatch Logs
 - UserData
 - AWS Systems Manager (Systems Manager)

For more information about Windows plug-ins, see [Configure a Windows instance using the EC2Config service \(p. 753\)](#).

Run Sysprep with the EC2Config service

Use the following procedure to create a standardized AMI using Sysprep and the EC2Config service.

1. In the Amazon EC2 console, locate or [create \(p. 151\)](#) an AMI that you want to duplicate.
2. Launch and connect to your Windows instance.
3. Customize it.
4. Specify configuration settings in the EC2Config service answer file:

```
C:\Program Files\Amazon\Ec2ConfigService\sysprep2008.xml
```

5. From the Windows **Start** menu, choose **All Programs**, and then choose **EC2ConfigService Settings**.
6. Choose the **Image** tab in the **Ec2 Service Properties** dialog box. For more information about the options and settings in the Ec2 Service Properties dialog box, see [Ec2 Service Properties \(p. 753\)](#).
7. Select an option for the Administrator password, and then select **Shutdown with Sysprep** or **Shutdown without Sysprep**. EC2Config edits the settings files based on the password option that you selected.
 - **Random**: EC2Config generates a password, encrypts it with user's key, and displays the encrypted password to the console. We disable this setting after the first launch so that this password persists if the instance is rebooted or stopped and started.
 - **Specify**: The password is stored in the Sysprep answer file in unencrypted form (clear text). When Sysprep runs next, it sets the Administrator password. If you shut down now, the password is set

immediately. When the service starts again, the Administrator password is removed. It's important to remember this password, as you can't retrieve it later.

- **Keep Existing:** The existing password for the Administrator account doesn't change when Sysprep is run or EC2Config is restarted. It's important to remember this password, as you can't retrieve it later.

8. Choose **OK**.

When you are asked to confirm that you want to run Sysprep and shut down the instance, click **Yes**. You'll notice that EC2Config runs Sysprep. Next, you are logged off the instance, and the instance is shut down. If you check the **Instances** page in the Amazon EC2 console, the instance state changes from Running to Stopping, and then finally to Stopped. At this point, it's safe to create an AMI from this instance.

You can manually invoke the Sysprep tool from the command line using the following command:

```
"%programfiles%\amazon\ec2configservice\"ec2config.exe -sysprep""
```

Note

The double quotation marks in the command are not required if your CMD shell is already in the C:\Program Files\Amazon\EC2ConfigService\ directory.

However, you must be very careful that the XML file options specified in the Ec2ConfigService\Settings folder are correct; otherwise, you might not be able to connect to the instance. For more information about the settings files, see [EC2Config settings files \(p. 760\)](#). For an example of configuring and then running Sysprep from the command line, see Ec2ConfigService\Scripts\InstallUpdates.ps1.

Modify an AMI

You can modify a limited set of Amazon Machine Image (AMI) attributes, such as the AMI's description and sharing properties. However, AMI content (volume binary data) can't be modified. To modify the AMI content, you must [create a new AMI \(p. 151\)](#).

Important

You can't modify the content (volume binary data) of an EBS-backed AMI because the snapshots that back them are immutable.

For the AMI attributes that can be modified, see [ModifyImageAttribute](#) in the *Amazon EC2 API Reference*.

The following topics provide instructions for using the Amazon EC2 console and AWS CLI to modify the attributes of an AMI:

- [Make an AMI public \(p. 132\)](#)
- [Share an AMI with specific organizations or organizational units \(p. 134\)](#)
- [Share an AMI with specific AWS accounts \(p. 141\)](#)
- [Use paid support \(p. 150\)](#)
- [Configure the AMI \(p. 870\)](#)

Copy an AMI

You can copy an Amazon Machine Image (AMI) within or across AWS Regions. You can copy both Amazon EBS-backed AMIs and instance-store-backed AMIs. You can copy AMIs with encrypted snapshots and also change encryption status during the copy process. You can copy AMIs that are shared with you.

Copying a source AMI results in an identical but distinct target AMI with its own unique identifier. You can change or deregister the source AMI with no effect on the target AMI. The reverse is also true.

With an Amazon EBS-backed AMI, each of its backing snapshots is copied to an identical but distinct target snapshot. If you copy an AMI to a new Region, the snapshots are complete (non-incremental) copies. If you encrypt unencrypted backing snapshots or encrypt them to a new KMS key, the snapshots are complete (non-incremental) copies. Subsequent copy operations of an AMI result in incremental copies of the backing snapshots.

Contents

- [Considerations \(p. 167\)](#)
- [Costs \(p. 167\)](#)
- [Permissions for copying an instance store-backed AMI \(p. 167\)](#)
- [Copy an AMI \(p. 168\)](#)
- [Stop a pending AMI copy operation \(p. 170\)](#)
- [Cross-Region copying \(p. 170\)](#)
- [Cross-account copying \(p. 171\)](#)
- [Encryption and copying \(p. 172\)](#)

Considerations

- You can use IAM policies to grant or deny users permissions to copy AMIs. Resource-level permissions specified for the CopyImage action apply only to the new AMI. You cannot specify resource-level permissions for the source AMI.
- AWS does not copy launch permissions or Amazon S3 bucket permissions from the source AMI to the new AMI. After the copy operation is complete, you can apply launch permissions and Amazon S3 bucket permissions to the new AMI.
- You can only copy user-defined AMI tags that you attached to the AMI. System tags (prefixed with aws :) and user-defined tags that are attached by other AWS accounts will not be copied.
- The CopyImage action is not supported for copying an AWS Marketplace AMI that was shared from another account. Instead, if you want to copy an AWS Marketplace AMI in another account, you must do the following: share the AWS Marketplace AMI with the other account and then, in the other account, launch an EC2 instance using the AWS Marketplace AMI. You can then create an AMI from the instance using the CreateImage action. The new AMI retains all the AWS Marketplace codes. Note that this process also applies to any AMIs that were directly or indirectly derived from an AWS Marketplace AMI. For more information about creating an AMI from an instance, see [Create a custom Windows AMI \(p. 151\)](#).

Costs

There are no charges for copying an AMI. However, standard storage and data transfer rates apply. If you copy an EBS-backed AMI, you will incur charges for the storage of any additional EBS snapshots.

Permissions for copying an instance store-backed AMI

To copy an instance store-backed AMI, the user must have the following Amazon S3 permissions: s3:CreateBucket, s3:GetBucketAcl, s3>ListAllMyBuckets, s3:GetObject, s3:PutObject, and s3:PutObjectAcl.

The following example policy allows the user to copy the AMI source in the specified bucket to the specified Region.

```
{
```

```
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Action": "s3>ListAllMyBuckets",
        "Resource": [
            "arn:aws:s3:::*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": "s3GetObject",
        "Resource": [
            "arn:aws:s3:::ami-source-bucket/*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [
            "s3>CreateBucket",
            "s3:GetBucketAcl",
            "s3:PutObjectAcl",
            "s3:PutObject"
        ],
        "Resource": [
            "arn:aws:s3:::amis-for-123456789012-in-us-east-1*"
        ]
    }
]
```

To find the Amazon Resource Name (ARN) of the AMI source bucket, open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>, in the navigation pane choose **AMIs**, and locate the bucket name in the **Source** column.

Note

The `s3>CreateBucket` permission is only needed the first time that the user copies an instance store-backed AMI to an individual Region. After that, the Amazon S3 bucket that is already created in the Region is used to store all future AMIs that you copy to that Region.

Copy an AMI

You can copy an AMI using the AWS Management Console, the AWS Command Line Interface or SDKs, or the Amazon EC2 API, all of which support the `CopyImage` action.

Prerequisite

Create or obtain an AMI backed by an Amazon EBS snapshot. Note that you can use the Amazon EC2 console to search a wide variety of AMIs provided by AWS. For more information, see [Create a custom Windows AMI \(p. 151\)](#) and [Finding an AMI](#).

New console

To copy an AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the console navigation bar, select the Region that contains the AMI.
3. In the navigation pane, choose **Images, AMIs** to display the list of AMIs available to you in the Region.
4. Select the AMI to copy and choose **Actions, Copy AMI**.

5. On the **Copy AMI** page, specify the following information:
 - **AMI copy name:** A name for the new AMI. You can include operating system information in the name, as we do not provide this information when displaying details about the AMI.
 - **AMI copy description:** By default, the description includes information about the source AMI so that you can distinguish a copy from its original. You can change this description as needed.
 - **Destination Region:** The Region in which to copy the AMI. For more information, see [Cross-Region copying \(p. 170\)](#).
 - **Copy tags:** Select this check box to include your user-defined AMI tags when copying the AMI. System tags (prefixed with aws :) and user-defined tags that are attached by other AWS accounts will not be copied.
 - **Encrypt EBS snapshots of AMI copy:** Select this check box to encrypt the target snapshots, or to re-encrypt them using a different key. If you have enabled [encryption by default \(p. 1925\)](#), the **Encrypt EBS snapshots of AMI copy** check box is selected and cannot be cleared. For more information, see [Encryption and copying \(p. 172\)](#).
 - **KMS key:** The KMS key to used to encrypt the target snapshots.
6. Choose **Copy AMI**.

The initial status of the new AMI is Pending. The AMI copy operation is complete when the status is Available.

Old console

To copy an AMI using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the console navigation bar, select the Region that contains the AMI. In the navigation pane, choose **Images, AMIs** to display the list of AMIs available to you in the Region.
3. Select the AMI to copy and choose **Actions, Copy AMI**.
4. In the **Copy AMI** dialog box, specify the following information and then choose **Copy AMI**:
 - **Destination region:** The Region in which to copy the AMI. For more information, see [Cross-Region copying \(p. 170\)](#).
 - **Name:** A name for the new AMI. You can include operating system information in the name, as we do not provide this information when displaying details about the AMI.
 - **Description:** By default, the description includes information about the source AMI so that you can distinguish a copy from its original. You can change this description as needed.
 - **Encryption:** Select this field to encrypt the target snapshots, or to re-encrypt them using a different key. If you have enabled [encryption by default \(p. 1925\)](#), the **Encryption** option is set and cannot be unset. For more information, see [Encryption and copying \(p. 172\)](#).
 - **KMS Key:** The KMS key to used to encrypt the target snapshots.
5. We display a confirmation page to let you know that the copy operation has been initiated and to provide you with the ID of the new AMI.

To check on the progress of the copy operation immediately, follow the provided link. To check on the progress later, choose **Done**, and then when you are ready, use the navigation bar to switch to the target Region (if applicable) and locate your AMI in the list of AMIs.

The initial status of the target AMI is pending and the operation is complete when the status is available.

To copy an AMI using the AWS CLI

You can copy an AMI using the [copy-image](#) command. You must specify both the source and destination Regions. You specify the source Region using the `--source-region` parameter. You can specify the destination Region using either the `--region` parameter or an environment variable. For more information, see [Configuring the AWS Command Line Interface](#).

When you encrypt a target snapshot during copying, you must specify these additional parameters: `--encrypted` and `--kms-key-id`.

For example commands, see the [Examples under copy-image](#) in the *AWS CLI Command Reference*.

To copy an AMI using the Tools for Windows PowerShell

You can copy an AMI using the [Copy-EC2Image](#) command. You must specify both the source and destination Regions. You specify the source Region using the `-SourceRegion` parameter. You can specify the destination Region using either the `-Region` parameter or the `Set-AWSDefaultRegion` command. For more information, see [Specifying AWS Regions](#).

When you encrypt a target snapshot during copying, you must specify these additional parameters: `-Encrypted` and `-KmsKeyId`.

Stop a pending AMI copy operation

You can stop a pending AMI copy as follows.

New console

To stop an AMI copy operation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the destination Region from the Region selector.
3. In the navigation pane, choose **AMIs**.
4. Select the AMI to stop copying and choose **Actions, Deregister AMI**.
5. When asked for confirmation, choose **Deregister AMI**.

Old console

To stop an AMI copy operation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the destination Region from the Region selector.
3. In the navigation pane, choose **AMIs**.
4. Select the AMI to stop copying and choose **Actions, Deregister**.
5. When asked for confirmation, choose **Continue**.

To stop an AMI copy operation using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

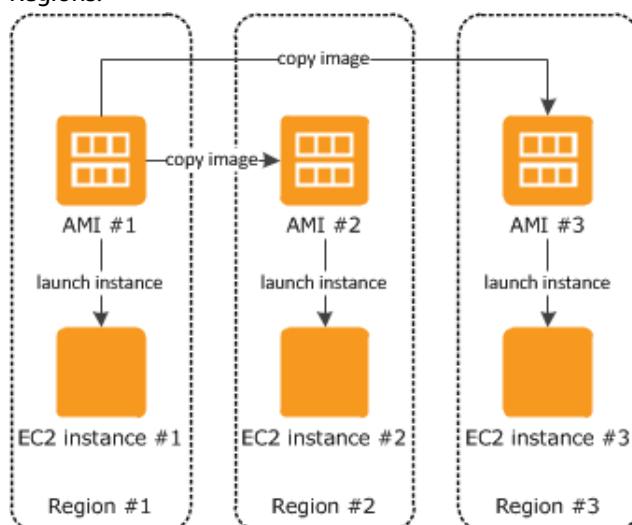

- [deregister-image](#) (AWS CLI)
- [Unregister-EC2Image](#) (AWS Tools for Windows PowerShell)

Cross-Region copying

Copying an AMI across geographically diverse Regions provides the following benefits:

- **Consistent global deployment:** Copying an AMI from one Region to another enables you to launch consistent instances in different Regions based on the same AMI.
- **Scalability:** You can more easily design and build global applications that meet the needs of your users, regardless of their location.
- **Performance:** You can increase performance by distributing your application, as well as locating critical components of your application in closer proximity to your users. You can also take advantage of Region-specific features, such as instance types or other AWS services.
- **High availability:** You can design and deploy applications across AWS Regions, to increase availability.

The following diagram shows the relations among a source AMI and two copied AMIs in different Regions, as well as the EC2 instances launched from each. When you launch an instance from an AMI, it resides in the same Region where the AMI resides. If you make changes to the source AMI and want those changes to be reflected in the AMIs in the target Regions, you must recopy the source AMI to the target Regions.

When you first copy an instance store-backed AMI to a Region, we create an Amazon S3 bucket for the AMIs copied to that Region. All instance store-backed AMIs that you copy to that Region are stored in this bucket. The bucket names have the following format: `amis-for-account-in-region-hash`. For example: `amis-for-123456789012-in-us-east-2-yhjmxvp6`.

Prerequisite

Prior to copying an AMI, you must ensure that the contents of the source AMI are updated to support running in a different Region. For example, you should update any database connection strings or similar application configuration data to point to the appropriate resources. Otherwise, instances launched from the new AMI in the destination Region may still use the resources from the source Region, which can impact performance and cost.

Limits

- Destination Regions are limited to 100 concurrent AMI copies.

Cross-account copying

You can share an AMI with another AWS account. Sharing an AMI does not affect the ownership of the AMI. The owning account is charged for the storage in the Region. For more information, see [Share an AMI with specific AWS accounts \(p. 141\)](#).

If you copy an AMI that has been shared with your account, you are the owner of the target AMI in your account. The owner of the source AMI is charged standard Amazon EBS or Amazon S3 transfer fees, and you are charged for the storage of the target AMI in the destination Region.

Resource permissions

To copy an AMI that was shared with you from another account, the owner of the source AMI must grant you read permissions for the storage that backs the AMI. The storage is either the associated EBS snapshot (for an Amazon EBS-backed AMI) or an associated S3 bucket (for an instance store-backed AMI). If the shared AMI has encrypted snapshots, the owner must share the key or keys with you as well. For more information about granting resource permissions, for EBS snapshots, see [Share an Amazon EBS snapshot \(p. 1810\)](#), and for S3 buckets, see [Identity and access management in Amazon S3](#) in the *Amazon Simple Storage Service User Guide*.

Note

To copy an AMI with its tags, you must have launch permissions for the source AMI.

Encryption and copying

The following table shows encryption support for various AMI-copying scenarios. While it is possible to copy an unencrypted snapshot to yield an encrypted snapshot, you cannot copy an encrypted snapshot to yield an unencrypted one.

Scenario	Description	Supported
1	Unencrypted-to-unencrypted	Yes
2	Encrypted-to-encrypted	Yes
3	Unencrypted-to-encrypted	Yes
4	Encrypted-to-unencrypted	No

Note

Encrypting during the CopyImage action applies only to Amazon EBS-backed AMIs. Because an instance store-backed AMI does not rely on snapshots, you cannot use copying to change its encryption status.

By default (i.e., without specifying encryption parameters), the backing snapshot of an AMI is copied with its original encryption status. Copying an AMI backed by an unencrypted snapshot results in an identical target snapshot that is also unencrypted. If the source AMI is backed by an encrypted snapshot, copying it results in an identical target snapshot that is encrypted by the same AWS KMS key. Copying an AMI backed by multiple snapshots preserves, by default, the source encryption status in each target snapshot.

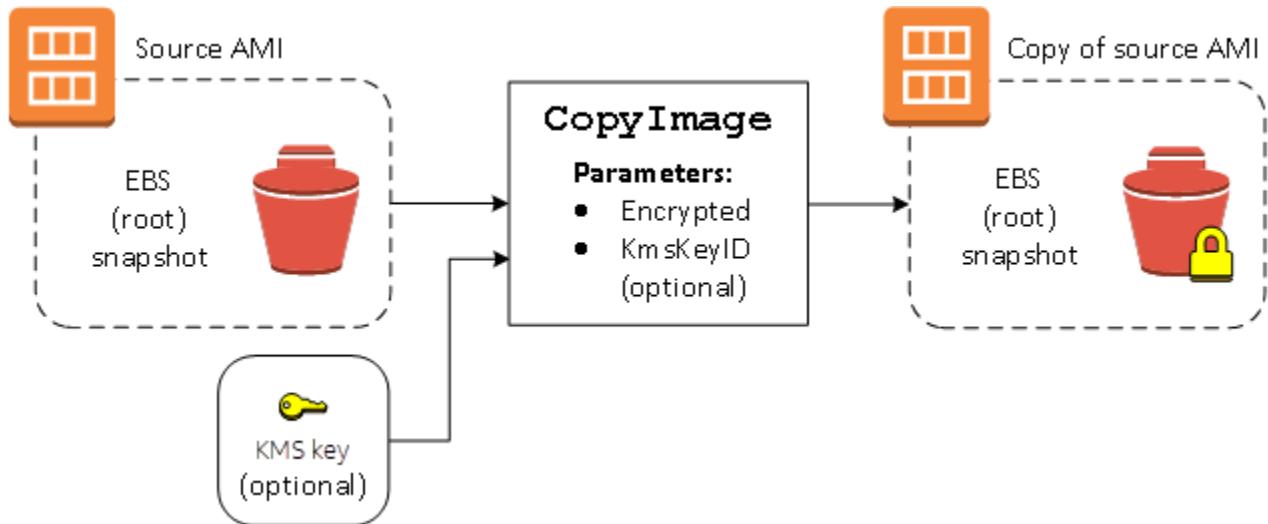

If you specify encryption parameters while copying an AMI, you can encrypt or re-encrypt its backing snapshots. The following example shows a non-default case that supplies encryption parameters to the CopyImage action in order to change the target AMI's encryption state.

Copy an unencrypted source AMI to an encrypted target AMI

In this scenario, an AMI backed by an unencrypted root snapshot is copied to an AMI with an encrypted root snapshot. The CopyImage action is invoked with two encryption parameters, including a customer managed key. As a result, the encryption status of the root snapshot changes, so that the target AMI is backed by a root snapshot containing the same data as the source snapshot, but encrypted using the specified key. You incur storage costs for the snapshots in both AMIs, as well as charges for any instances you launch from either AMI.

Note

Enabling [encryption by default \(p. 1925\)](#) has the same effect as setting the Encrypted parameter to true for all snapshots in the AMI.

Setting the Encrypted parameter encrypts the single snapshot for this instance. If you do not specify the KmsKeyId parameter, the default customer managed key is used to encrypt the snapshot copy.

For more information about copying AMIs with encrypted snapshots, see [Use encryption with EBS-backed AMIs \(p. 193\)](#).

Store and restore an AMI using S3

You can store an Amazon Machine Image (AMI) in an Amazon S3 bucket, copy the AMI to another S3 bucket, and then restore it from the S3 bucket. By storing and restoring an AMI using S3 buckets, you can copy AMIs from one AWS partition to another, for example, from the main commercial partition to the AWS GovCloud (US) partition. You can also make archival copies of AMIs by storing them in an S3 bucket.

The supported APIs for storing and restoring an AMI using S3 are `CreateStoreImageTask`, `DescribeStoreImageTasks`, and `CreateRestoreImageTask`.

`CopyImage` is the recommended API to use for copying AMIs *within* an AWS partition. However, `CopyImage` can't copy an AMI to *another* partition.

For information about the AWS partitions, see [partition](#) on the [Amazon Resource Names \(ARNs\)](#) page in the [AWS General Reference](#).

Warning

Ensure that you comply with all applicable laws and business requirements when moving data between AWS partitions or AWS Regions, including, but not limited to, any applicable government regulations and data residency requirements.

Topics

- [Use cases \(p. 174\)](#)
- [How the AMI store and restore APIs work \(p. 175\)](#)
- [Limitations \(p. 176\)](#)
- [Costs \(p. 176\)](#)
- [Securing your AMIs \(p. 176\)](#)
- [Permissions for storing and restoring AMIs using S3 \(p. 177\)](#)

- [Work with the AMI store and restore APIs \(p. 178\)](#)
- [Use file paths in S3 \(p. 179\)](#)

Use cases

Use the store and restore APIs to do the following:

- [Copy an AMI from one AWS partition to another AWS partition \(p. 174\)](#)
- [Make archival copies of AMIs \(p. 174\)](#)

Copy an AMI from one AWS partition to another AWS partition

By storing and restoring an AMI using S3 buckets, you can copy an AMI from one AWS partition to another, or from one AWS Region to another. In the following example, you copy an AMI from the main commercial partition to the AWS GovCloud (US) partition, specifically from the us-east-2 Region to the us-gov-east-1 Region.

To copy an AMI from one partition to another, follow these steps:

- Store the AMI in an S3 bucket in the current Region by using `CreateStoreImageTask`. In this example, the S3 bucket is located in us-east-2. For an example command, see [Store an AMI in an S3 bucket \(p. 178\)](#).
- Monitor the progress of the store task by using `DescribeStoreImageTasks`. The object becomes visible in the S3 bucket when the task is completed. For an example command, see [Describe the progress of an AMI store task \(p. 178\)](#).
- Copy the stored AMI object to an S3 bucket in the target partition using a procedure of your choice. In this example, the S3 bucket is located in us-gov-east-1.

Note

Because you need different AWS credentials for each partition, you can't copy an S3 object directly from one partition to another. The process for copying an S3 object across partitions is outside the scope of this documentation. We provide the following copy processes as examples, but you must use the copy process that meets your security requirements.

- To copy one AMI across partitions, the copy process could be as straightforward as the following: [Download the object](#) from the source bucket to an intermediate host (for example, an EC2 instance or a laptop), and then [upload the object](#) from the intermediate host to the target bucket. For each stage of the process, use the AWS credentials for the partition.
- For more sustained usage, consider developing an application that manages the copies, potentially using S3 [multipart downloads and uploads](#).
- Restore the AMI from the S3 bucket in the target partition by using `CreateRestoreImageTask`. In this example, the S3 bucket is located in us-gov-east-1. For an example command, see [Restore an AMI from an S3 bucket \(p. 178\)](#).
- Monitor the progress of the restore task by describing the AMI to check when its state becomes available. You can also monitor the progress percentages of the snapshots that make up the restored AMI by describing the snapshots.

Make archival copies of AMIs

You can make archival copies of AMIs by storing them in an S3 bucket. For an example command, see [Store an AMI in an S3 bucket \(p. 178\)](#).

The AMI is packed into a single object in S3, and all of the AMI metadata (excluding sharing information) is preserved as part of the stored AMI. The AMI data is compressed as part of the storage process. AMIs

that contain data that can easily be compressed will result in smaller objects in S3. To reduce costs, you can use less expensive S3 storage tiers. For more information, see [Amazon S3 Storage Classes](#) and [Amazon S3 pricing](#)

How the AMI store and restore APIs work

To store and restore an AMI using S3, you use the following APIs:

- `CreateStoreImageTask` – Stores the AMI in an S3 bucket
- `DescribeStoreImageTasks` – Provides the progress of the AMI store task
- `CreateRestoreImageTask` – Restores the AMI from an S3 bucket

How the APIs work

- [CreateStoreImageTask \(p. 175\)](#)
- [DescribeStoreImageTasks \(p. 175\)](#)
- [CreateRestoreImageTask \(p. 176\)](#)

CreateStoreImageTask

The [CreateStoreImageTask \(p. 178\)](#) API stores an AMI as a single object in an S3 bucket.

The API creates a task that reads all of the data from the AMI and its snapshots, and then uses an [S3 multipart upload](#) to store the data in an S3 object. The API takes all of the components of the AMI, including most of the non-Region-specific AMI metadata, and all the EBS snapshots contained in the AMI, and packs them into a single object in S3. The data is compressed as part of the upload process to reduce the amount of space used in S3, so the object in S3 might be smaller than the sum of the sizes of the snapshots in the AMI.

If there are AMI and snapshot tags visible to the account calling this API, they are preserved.

The object in S3 has the same ID as the AMI, but with a .bin extension. The following data is also stored as S3 metadata tags on the S3 object: AMI name, AMI description, AMI registration date, AMI owner account, and a timestamp for the store operation.

The time it takes to complete the task depends on the size of the AMI. It also depends on how many other tasks are in progress because tasks are queued. You can track the progress of the task by calling the [DescribeStoreImageTasks \(p. 178\)](#) API.

The sum of the sizes of all the AMIs in progress is limited to 600 GB of EBS snapshot data per account. Further task creation will be rejected until the tasks in progress are less than the limit. For example, if an AMI with 100 GB of snapshot data and another AMI with 200 GB of snapshot data are currently being stored, another request will be accepted, because the total in progress is 300 GB, which is less than the limit. But if a single AMI with 800 GB of snapshot data is currently being stored, further tasks are rejected until the task is completed.

DescribeStoreImageTasks

The [DescribeStoreImageTasks \(p. 178\)](#) API describes the progress of the AMI store tasks. You can describe tasks for specified AMIs. If you don't specify AMIs, you get a paginated list of all of the store image tasks that have been processed in the last 31 days.

For each AMI task, the response indicates if the task is `InProgress`, `Completed`, or `Failed`. For tasks `InProgress`, the response shows an estimated progress as a percentage.

Tasks are listed in reverse chronological order.

Currently, only tasks from the previous month can be viewed.

CreateRestoreImageTask

The [CreateRestoreImageTask \(p. 178\)](#) API starts a task that restores an AMI from an S3 object that was previously created by using a [CreateStoreImageTask \(p. 178\)](#) request.

The restore task can be performed in the same or a different Region in which the store task was performed.

The S3 bucket from which the AMI object will be restored must be in the same Region in which the restore task is requested. The AMI will be restored in this Region.

The AMI is restored with its metadata, such as the name, description, and block device mappings corresponding to the values of the stored AMI. The name must be unique for AMIs in the Region for this account. If you do not provide a name, the new AMI gets the same name as the original AMI. The AMI gets a new AMI ID that is generated at the time of the restore process.

The time it takes to complete the AMI restoration task depends on the size of the AMI. It also depends on how many other tasks are in progress because tasks are queued. You can view the progress of the task by describing the AMI ([describe-images](#)) or its EBS snapshots ([describe-snapshots](#)). If the task fails, the AMI and snapshots are moved to a failed state.

The sum of the sizes of all of the AMIs in progress is limited to 300 GB (based on the size after restoration) of EBS snapshot data per account. Further task creation will be rejected until the tasks in progress are less than the limit.

Limitations

- To store an AMI, your AWS account must either own the AMI and its snapshots, or the AMI and its snapshots must be [shared directly with your account \(p. 141\)](#). You can't store an AMI if it is only [publicly shared \(p. 132\)](#).
- Only EBS-backed AMIs can be stored using these APIs.
- Paravirtual (PV) AMIs are not supported.
- The size of an AMI (before compression) that can be stored is limited to 5,000 GB.
- Quota on [store image \(p. 178\)](#) requests: 600 GB of storage work (snapshot data) in progress.
- Quota on [restore image \(p. 178\)](#) requests: 300 GB of restore work (snapshot data) in progress.
- For the duration of the store task, the snapshots must not be deleted and the IAM principal doing the store must have access to the snapshots, otherwise the store process will fail.
- You can't create multiple copies of an AMI in the same S3 bucket.
- An AMI that is stored in an S3 bucket can't be restored with its original AMI ID. You can mitigate this by using [AMI aliasing](#).
- Currently the store and restore APIs are only supported by using the AWS Command Line Interface, AWS SDKs, and Amazon EC2 API. You can't store and restore an AMI using the Amazon EC2 console.

Costs

When you store and restore AMIs using S3, you are charged for the services that are used by the store and restore APIs, and for data transfer. The APIs use S3 and the EBS Direct API (used internally by these APIs to access the snapshot data). For more information, see [Amazon S3 pricing](#) and [Amazon EBS pricing](#).

Securing your AMIs

To use the store and restore APIs, the S3 bucket and the AMI must be in the same Region. It is important to ensure that the S3 bucket is configured with sufficient security to secure the content of the AMI and that the security is maintained for as long as the AMI objects remain in the bucket. If this can't be done,

use of these APIs is not recommended. Ensure that public access to the S3 bucket is not allowed. We recommend enabling [Server Side Encryption](#) for the S3 buckets in which you store the AMIs, although it's not required.

For information about how to set the appropriate security settings for your S3 buckets, review the following security topics:

- [Blocking public access to your Amazon S3 storage](#)
- [Setting default server-side encryption behavior for Amazon S3 buckets](#)
- [What S3 bucket policy should I use to comply with the AWS Config rule s3-bucket-ssl-requests-only?](#)
- [Enabling Amazon S3 server access logging](#)

When the AMI snapshots are copied to the S3 object, the data is then copied over TLS connections. You can store AMIs with encrypted snapshots, but the snapshots are decrypted as part of the store process.

Permissions for storing and restoring AMIs using S3

If your IAM principals will store or restore AMIs using Amazon S3, you need to grant them the required permissions.

The following example policy includes all of the actions that are required to allow an IAM principal to carry out the store and restore tasks.

You can also create IAM policies that grant principals access to specific resources only. For more example policies, see [Access management for AWS resources](#) in the *IAM User Guide*.

Note

If the snapshots that make up the AMI are encrypted, or if your account is enabled for encryption by default, your IAM principal must have permission to use the KMS key. For more information, see [Permissions to use AWS KMS keys \(p. 1832\)](#).

Work with the AMI store and restore APIs

Topics

- [Store an AMI in an S3 bucket \(p. 178\)](#)
- [Describe the progress of an AMI store task \(p. 178\)](#)
- [Restore an AMI from an S3 bucket \(p. 178\)](#)

Store an AMI in an S3 bucket

To store an AMI (AWS CLI)

Use the [create-store-image-task](#) command. Specify the ID of the AMI and the name of the S3 bucket in which to store the AMI.

```
aws ec2 create-store-image-task \
--image-id ami-1234567890abcdef0 \
--bucket myamibucket
```

Expected output

```
{
    "ObjectKey": "ami-1234567890abcdef0.bin"
}
```

Describe the progress of an AMI store task

To describe the progress of an AMI store task (AWS CLI)

Use the [describe-store-image-tasks](#) command.

```
aws ec2 describe-store-image-tasks
```

Expected output

```
{
    "AmiId": "ami-1234567890abcdef0",
    "Bucket": "myamibucket",
    "ProgressPercentage": 17,
    "S3ObjectKey": "ami-1234567890abcdef0.bin",
    "StoreTaskState": "InProgress",
    "StoreTaskFailureReason": null,
    "TaskStartTime": "2021-01-01T01:01:01.001Z"
}
```

Restore an AMI from an S3 bucket

To restore an AMI (AWS CLI)

Use the [create-restore-image-task](#) command. Using the values for S3ObjectKey and Bucket from the `describe-store-image-tasks` output, specify the object key of the AMI and the name of the S3 bucket to which the AMI was copied. Also specify a name for the restored AMI. The name must be unique for AMIs in the Region for this account.

Note

The restored AMI gets a new AMI ID.

```
aws ec2 create-restore-image-task \
--object-key ami-1234567890abcdef0.bin \
--bucket myamibucket \
--name "New AMI Name"
```

Expected output

```
{  
    "ImageId": "ami-0eab20fe36f83e1a8"  
}
```

Use file paths in S3

You can use file paths when storing and restoring AMIs, in the following way:

- When storing an AMI in S3, the file path can be added to the bucket name. Internally, the system separates the path from the bucket name, and then adds the path to the object key that is generated to store the AMI. The full object path is shown in the response from the API call.
- When restoring the AMI, because an object key parameter is available, the path can be added to the beginning of the object key value.

You can use file paths when using the AWS CLI and SDKs.

Example: Use a file path when storing and restoring an AMI (AWS CLI)

The following example first stores an AMI in S3, with the file path appended to the bucket name. The example then restores the AMI from S3, with the file path prepended to the object key parameter.

1. Store the AMI. For --bucket, specify the file path after the bucket name, as follows:

```
aws ec2 create-store-image-task \
--image-id ami-1234567890abcdef0 \
--bucket myamibucket/path1/path2
```

Expected output

```
{  
    "ObjectKey": "path1/path2/ami-1234567890abcdef0.bin"  
}
```

2. Restore the AMI. For --object-key, specify the value from the output in the previous step, which includes the file path.

```
aws ec2 create-restore-image-task \
--object-key path1/path2/ami-1234567890abcdef0.bin \
--bucket myamibucket \
--name "New AMI Name"
```

Deprecate an AMI

You can deprecate an AMI to indicate that it is out of date and should not be used. You can also specify a future deprecation date for an AMI, indicating when the AMI will be out of date. For example, you might deprecate an AMI that is no longer actively maintained, or you might deprecate an AMI that has been

superseded by a newer version. By default, deprecated AMIs do not appear in AMI listings, preventing new users from using out-of-date AMIs. However, existing users and launch services, such as launch templates and Auto Scaling groups, can continue to use a deprecated AMI by specifying its ID. To delete the AMI so that users and services cannot use it, you must [deregister \(p. 185\)](#) it.

After an AMI is deprecated:

- For AMI users, the deprecated AMI does not appear in [DescribeImages](#) API calls unless you specify its ID or specify that deprecated AMIs must appear. AMI owners continue to see deprecated AMIs in [DescribeImages](#) API calls.
- For AMI users, the deprecated AMI is not available to select via the EC2 console. For example, a deprecated AMI does not appear in the AMI catalog in the launch instance wizard. AMI owners continue to see deprecated AMIs in the EC2 console.
- For AMI users, if you know the ID of a deprecated AMI, you can continue to launch instances using the deprecated AMI by using the API, CLI, or the SDKs.
- Launch services, such as launch templates and Auto Scaling groups, can continue to reference deprecated AMIs.
- EC2 instances that were launched using an AMI that is subsequently deprecated are not affected, and can be stopped, started, and rebooted.

You can deprecate both private and public AMIs.

You can also create Amazon Data Lifecycle Manager EBS-backed AMI policies to automate the deprecation of EBS-backed AMIs. For more information, see [Automate AMI lifecycles \(p. 1875\)](#).

Note

By default, the deprecation date of all public AMIs is set to two years from the AMI creation date. You can set the deprecation date to earlier than two years. To cancel the deprecation date, or to move the deprecation to a later date, you must make the AMI private by only [sharing it with specific AWS accounts \(p. 141\)](#).

Topics

- [Costs \(p. 180\)](#)
- [Limitations \(p. 176\)](#)
- [Deprecate an AMI \(p. 180\)](#)
- [Describe deprecated AMIs \(p. 182\)](#)
- [Cancel the deprecation of an AMI \(p. 184\)](#)

Costs

When you deprecate an AMI, the AMI is not deleted. The AMI owner continues to pay for the AMI's snapshots. To stop paying for the snapshots, the AMI owner must delete the AMI by [deregistering \(p. 185\)](#) it.

Limitations

- To deprecate an AMI, you must be the owner of the AMI.

Deprecate an AMI

You can deprecate an AMI on a specific date and time. You must be the AMI owner to perform this procedure.

Console

To deprecate an AMI on a specific date

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then choose **Actions, Manage AMI Deprecation**. You can select multiple AMIs to set the same deprecation date of several AMIs at once.
5. Select the **Enable** check box, and then enter the deprecation date and time.

The upper limit for the deprecation date is 10 years from now, except for public AMIs, where the upper limit is 2 years from the creation date. You can't specify a date in the past.

6. Choose **Save**.

AWS CLI

To deprecate an AMI on a specific date

Use the [enable-image-deprecation](#) command. Specify the ID of the AMI and the date and time on which to deprecate the AMI. If you specify a value for seconds, Amazon EC2 rounds the seconds to the nearest minute.

The upper limit for deprecate-at is 10 years from now, except for public AMIs, where the upper limit is 2 years from the creation date. You can't specify a date in the past.

```
aws ec2 enable-image-deprecation \
  --image-id ami-1234567890abcdef0 \
  --deprecate-at "2021-10-15T13:17:12.000Z"
```

Expected output

```
{  
    "Return": "true"  
}
```

Last launched time

`LastLaunchedTime` is a timestamp that indicates when your AMI was last used to launch an instance. AMIs that have not been used recently to launch an instance might be good candidates for deprecation or [deregistering \(p. 185\)](#).

Note

- When an AMI is used to launch an instance, there is a 24-hour delay before that usage is reported.
- `lastLaunchedTime` data is available starting April 2017.

Console

To view the last launched time of an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.

4. Select the AMI, and then check the **Last launched time** field (if you selected the check box next to the AMI, it's located on the **Details** tab). The field shows the date and time when the AMI was last used to launch an instance.

AWS CLI

To view the last launched time of an AMI

Run the [describe-image-attribute](#) command and specify `--attribute lastLaunchedTime`. You must be the AMI owner to run this command.

```
aws ec2 describe-image-attribute \
--image-id ami-1234567890example \
--attribute lastLaunchedTime
```

Example output

```
{  
    "LastLaunchedTime": {  
        "Value": "2022-02-10T02:03:18Z"  
    },  
    "ImageId": "ami-1234567890example",  
}
```

Describe deprecated AMIs

You can view the deprecation date and time of an AMI, and filter all the AMIs by deprecation date. You can also use the AWS CLI to describe all the AMIs that have been deprecated, where the deprecation date is in the past.

Console

To view the deprecation date of an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**, and then select the AMI.
3. Check the **Deprecation time** field (if you selected the check box next to the AMI, it's located on the **Details** tab). The field shows the deprecation date and time of the AMI. If the field is empty, the AMI is not deprecated.

To filter AMIs by deprecation date

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me** or **Private images** (private images include AMIs that are shared with you as well as owned by you).
4. In the Search bar, enter **Deprecation time** (as you enter the letters, the **Deprecation time** filter appears), and then choose an operator and a date and time.

AWS CLI

When you describe all AMIs using the [describe-images](#) command, the results are different depending on whether you are an AMI user or the AMI owner.

- If you are an AMI user:

By default, when you describe all AMIs using the [describe-images](#) command, deprecated AMIs that are not owned by you, but which are shared with you, do not appear in the results. This is because the default is `--no-include-deprecated`. To include deprecated AMIs in the results, you must specify the `--include-deprecated` parameter.

- If you are the AMI owner:

When you describe all AMIs using the [describe-images](#) command, all the AMIs that you own, including deprecated AMIs, appear in the results. You do not need to specify the `--include-deprecated` parameter. Furthermore, you cannot exclude deprecated AMIs that you own from the results by using `--no-include-deprecated`.

If an AMI is deprecated, the `DeprecationTime` field appears in the results.

Note

A deprecated AMI is an AMI whose deprecation date is in the past. If you have set the deprecation date to a date in the future, the AMI is not yet deprecated.

To include all deprecated AMIs when describing all AMIs

Use the [describe-images](#) command and specify the `--include-deprecated` parameter to include all deprecated AMIs that are not owned by you in the results.

```
aws ec2 describe-images \
  --region us-east-1 \
  --owners 123456example
  --include-deprecated
```

To describe the deprecation date of an AMI

Use the [describe-images](#) command and specify the ID of the AMI.

Note that if you specify `--no-include-deprecated` together with the AMI ID, the deprecated AMI will be returned in the results.

```
aws ec2 describe-images \
  --region us-east-1 \
  --image-ids ami-1234567890EXAMPLE
```

Expected output

The `DeprecationTime` field displays the date on which the AMI is set to be deprecated. If the AMI is not set to be deprecated, the `DeprecationTime` field does not appear in the output.

```
{

```

Cancel the deprecation of an AMI

You can cancel the deprecation of an AMI, which removes the date and time from the **Deprecation time** field (console) or the **DeprecationTime** field from the [describe-images](#) output (AWS CLI). You must be the AMI owner to perform this procedure.

Console

To cancel the deprecation of an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then choose **Actions, Manage AMI Deprecation**. You can select multiple AMIs to cancel the deprecation of several AMIs at once.
5. Clear the **Enable** check box, and then choose **Save**.

AWS CLI

To cancel the deprecation of an AMI

Use the [disable-image-deprecation](#) command and specify the ID of the AMI.

```
aws ec2 disable-image-deprecation \
--image-id ami-1234567890abcdef0
```

Expected output

```
{
```

```
    "Return": "true"  
}
```

Deregister your AMI

You can deregister an AMI when you have finished using it. After you deregister an AMI, you can't use it to launch new instances.

When you deregister an AMI, it doesn't affect any instances that you've already launched from the AMI or any snapshots created during the AMI creation process. You'll continue to incur usage costs for these instances and storage costs for the snapshot. Therefore, you should terminate any instances and delete any snapshots that you're finished with.

Contents

- [Considerations \(p. 185\)](#)
- [Clean up your AMI \(p. 185\)](#)
- [Last launched time \(p. 188\)](#)

Considerations

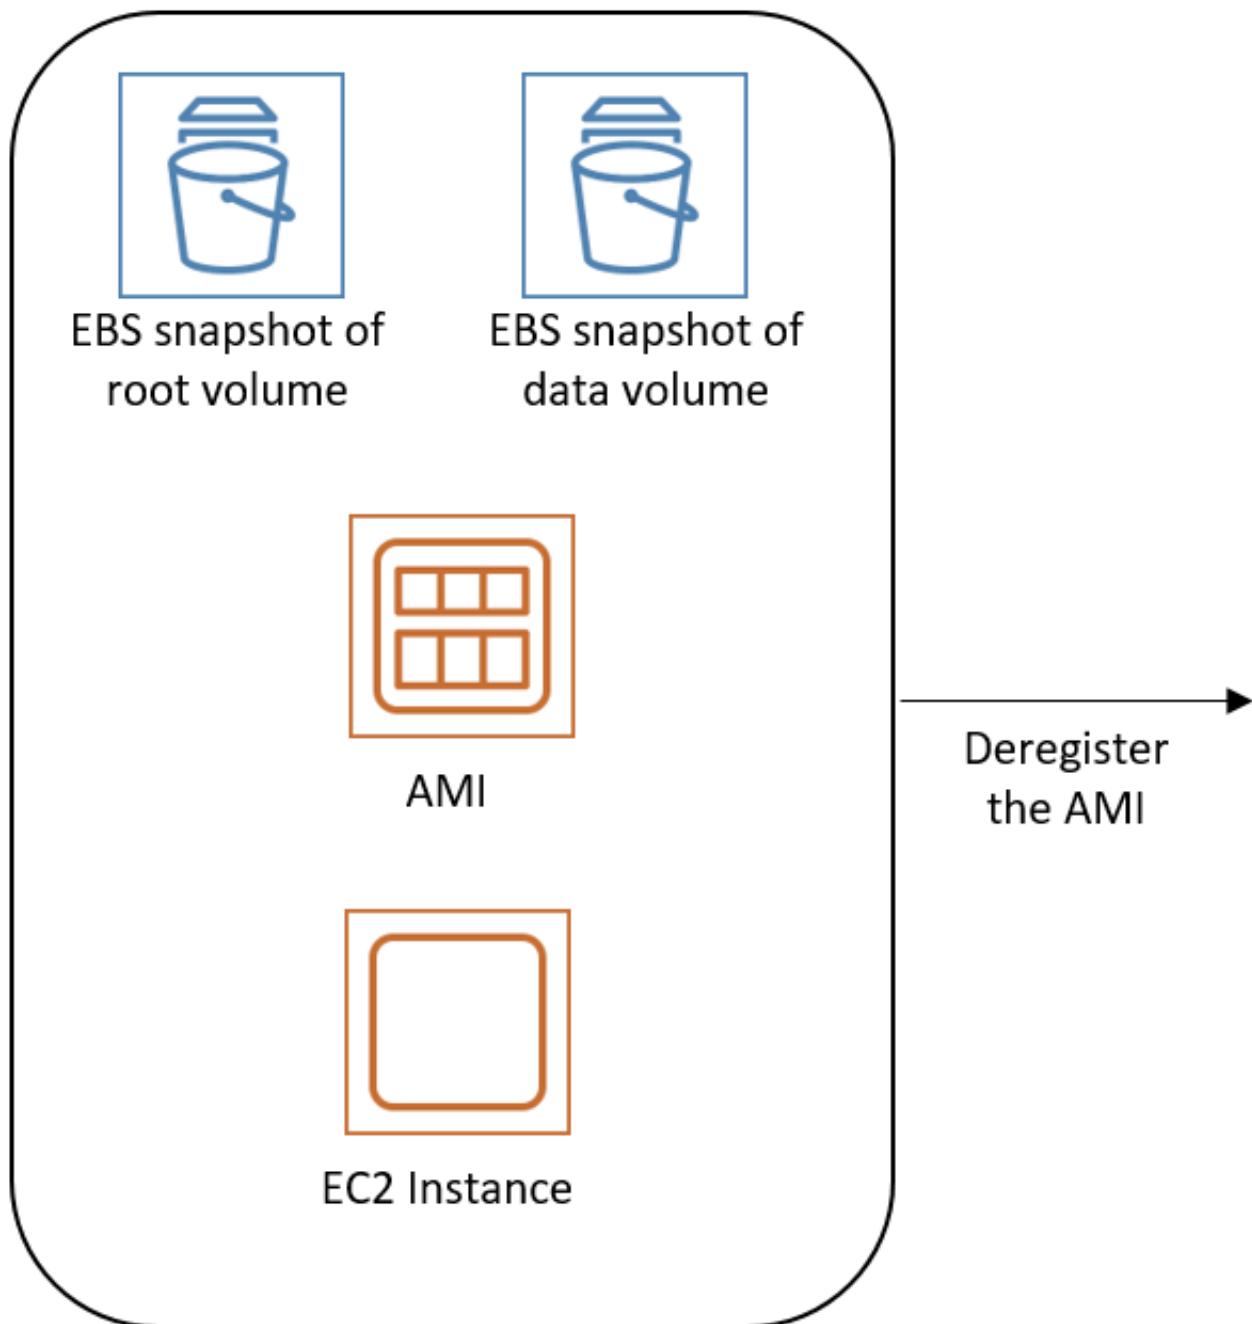

The following considerations apply to deregistering AMIs:

- You can't deregister an AMI that is not owned by your account.
- You can't deregister an AMI that is managed by the AWS Backup service using Amazon EC2. Instead, use AWS Backup to delete the corresponding recovery points in the backup vault. For more information, see [Deleting backups](#) in the *AWS Backup Developer Guide*.

Clean up your AMI

When you deregister an AMI, it doesn't affect the snapshot(s) that were created for the volume(s) of the instance during the AMI creation process. You'll continue to incur storage costs for the snapshots. Therefore, if you are finished with the snapshots, you should delete them.

The following diagram illustrates the process for cleaning up your AMI.

Your AMI, its snapshots, and an instance launched from the AMI

You can use one of the following methods to clean up your AMI.

New console

To clean up your AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. **Deregister the AMI**
 - a. In the navigation pane, choose **AMIs**.
 - b. Select the AMI to deregister, and take note of its ID—this can help you find the snapshots to delete in the next step.
 - c. Choose **Actions, Deregister AMI**. When prompted for confirmation, choose **Deregister AMI**.
3. **Note**

It might take a few minutes before the console removes the AMI from the list.
Choose **Refresh** to refresh the status.
4. **Delete snapshots that are no longer needed**
 - a. In the navigation pane, choose **Snapshots**.
 - b. Select a snapshot to delete (look for the AMI ID from the prior step in the **Description** column).
 - c. Choose **Actions, Delete snapshot**. When prompted for confirmation, choose **Delete**.
5. **(Optional) Terminate instances**

If you are finished with an instance that you launched from the AMI, you can terminate it.

- a. In the navigation pane, choose **Instances**, and then select the instance to terminate.
- b. Choose **Instance state, Terminate instance**. When prompted for confirmation, choose **Terminate**.

Old console

To clean up your AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. **Deregister the AMI**
 - a. In the navigation pane, choose **AMIs**.
 - b. Select the AMI to deregister, and take note of its ID — this can help you find the snapshots to delete in the next step.
 - c. Choose **Actions, Deregister**. When prompted for confirmation, choose **Continue**.
3. **Note**

It may take a few minutes before the console removes the AMI from the list.
Choose **Refresh** to refresh the status.
4. **Delete snapshots that are no longer needed**
 - a. In the navigation pane, choose **Snapshots**.
 - b. Select a snapshot to delete (look for the AMI ID from the prior step in the **Description** column).
 - c. Choose **Actions, Delete**. When prompted for confirmation, choose **Yes, Delete**.
5. **(Optional) Terminate instances**

If you are finished with an instance that you launched from the AMI, you can terminate it.

- a. In the navigation pane, choose **Instances**, and then select the instance to terminate.

- b. Choose **Actions, Instance State, Terminate**. When prompted for confirmation, choose **Yes, Terminate**.

AWS CLI

Follow these steps to clean up your AMI

1. **Deregister the AMI**

Deregister the AMI using the [deregister-image](#) command:

```
aws ec2 deregister-image --image-id ami-12345678
```

2. **Delete snapshots that are no longer needed**

Delete snapshots that are no longer needed by using the [delete-snapshot](#) command:

```
aws ec2 delete-snapshot --snapshot-id snap-1234567890abcdef0
```

3. **Terminate instances (Optional)**

If you are finished with an instance that you launched from the AMI, you can terminate it by using the [terminate-instances](#) command:

```
aws ec2 terminate-instances --instance-ids i-12345678
```

PowerShell

Follow these steps to clean up your AMI

1. **Deregister the AMI**

Deregister the AMI using the [Unregister-EC2Image](#) cmdlet:

```
Unregister-EC2Image -ImageId ami-12345678
```

2. **Delete snapshots that are no longer needed**

Delete snapshots that are no longer needed by using the [Remove-EC2Snapshot](#) cmdlet:

```
Remove-EC2Snapshot -SnapshotId snap-12345678
```

3. **Terminate instances (Optional)**

If you are finished with an instance that you launched from the AMI, you can terminate it by using the [Remove-EC2Instance](#) cmdlet:

```
Remove-EC2Instance -InstanceId i-12345678
```

Last launched time

`LastLaunchedTime` is a timestamp that indicates when your AMI was last used to launch an instance. AMIs that have not been used recently to launch an instance might be good candidates for deregistering or [deprecation \(p. 179\)](#).

Note

- When the AMI is used to launch an instance, there is a 24-hour delay before that usage is reported.
- lastLaunchedTime data is available starting April 2017.

Console

To view the last launched time of an AMI

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then check the **Last launched time** field (if you selected the check box next to the AMI, it's located on the **Details** tab). The field shows the date and time when the AMI was last used to launch an instance.

AWS CLI

To view the last launched time of an AMI

Run the [describe-image-attribute](#) command and specify --attribute lastLaunchedTime. You must be the AMI owner to run this command.

```
aws ec2 describe-image-attribute \
--image-id ami-1234567890example \
--attribute lastLaunchedTime
```

Example output

```
{
    "LastLaunchedTime": {
        "Value": "2022-02-10T02:03:18Z"
    },
    "ImageId": "ami-1234567890example",
}
```

Recover AMIs from the Recycle Bin

Recycle Bin is a data recovery feature that enables you to restore accidentally deleted Amazon EBS snapshots and EBS-backed AMIs. When using Recycle Bin, if your resources are deleted, they are retained in the Recycle Bin for a time period that you specify before being permanently deleted.

You can restore a resource from the Recycle Bin at any time before its retention period expires. After you restore a resource from the Recycle Bin, the resource is removed from the Recycle Bin and you can use it in the same way that you use any other resource of that type in your account. If the retention period expires and the resource is not restored, the resource is permanently deleted from the Recycle Bin and it is no longer available for recovery.

AMIs in the Recycle Bin do not incur any additional charges.

For more information, see [Recycle Bin \(p. 2045\)](#).

Topics

- [Permissions for working with AMIs in the Recycle Bin \(p. 190\)](#)
- [View AMIs in the Recycle Bin \(p. 191\)](#)
- [Restore AMIs from the Recycle Bin \(p. 192\)](#)

Permissions for working with AMIs in the Recycle Bin

By default, users don't have permission to work with AMIs that are in the Recycle Bin. To allow users to work with these resources, you must create IAM policies that grant permission to use specific resources and API actions. Once the policies are created, you must add permissions to your users, groups, or roles.

To view and recover AMIs that are in the Recycle Bin, users must have the following permissions:

- `ec2>ListImagesInRecycleBin`
- `ec2:RestoreImageFromRecycleBin`

To manage tags for AMIs in the Recycle Bin, users need the following additional permissions.

- `ec2>CreateTags`
- `ec2>DeleteTags`

To use the Recycle Bin console, users need the `ec2:DescribeTags` permission.

The following is an example IAM policy. It includes the `ec2:DescribeTags` permission for console users, and it includes the `ec2:CreateTags` and `ec2:DeleteTags` permissions for managing tags. If the permissions are not needed, you can remove them from the policy.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "ec2>ListImagesInRecycleBin",  
                "ec2:RestoreImageFromRecycleBin"  
            ],  
            "Resource": "*"  
        },

                "ec2>DeleteTags",  
                "ec2:DescribeTags"  
            ],  
            "Resource": "arn:aws:ec2:Region::image/*"  
        }  
    ]  
}
```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center (successor to AWS Single Sign-On):

Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide*.

- Users managed in IAM through an identity provider:

Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.

- IAM users:
 - Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the *IAM User Guide*.
 - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

For more information about the permissions needed to use Recycle Bin, see [Permissions for working with Recycle Bin and retention rules \(p. 2049\)](#).

View AMIs in the Recycle Bin

While an AMI is in the Recycle Bin, you can view limited information about it, including:

- The name, description, and unique ID of the AMI.
 - The date and time when the AMI was deleted and it entered Recycle Bin.
 - The date and time when the retention period expires. The AMI will be permanently deleted at this time.

You can view the AMIs in the Recycle Bin using one of the following methods.

Recycle Bin console

To view deleted AMIs in the Recycle Bin using the console

1. Open the Recycle Bin console at console.aws.amazon.com/rbin/home/.
 2. In the navigation pane, choose **Recycle Bin**.
 3. The grid lists all of the resources that are currently in the Recycle Bin. To view the details for a specific AMI, select it in the grid, and choose **Actions, View details**.

AWS CLI

To view deleted AMIs in the Recycle Bin using the AWS CLI

Use the [list-images-in-recycle-bin](#) AWS CLI command. To view specific AMIs, include the `--image-id` option and specify the IDs of the AMIs to view. You can specify up to 20 IDs in a single request.

To view all of the AMIs in the Recycle Bin, omit the `--image-id` option. If you do not specify a value for `--max-items`, the command returns 1,000 items per page, by default. For more information, see [Pagination](#) in the *Amazon EC2 API Reference*.

```
C:\> aws ec2 list-images-in-recycle-bin --image-id ami_id
```

For example, the following command provides information about AMI ami-01234567890abcdef in the Recycle Bin.

```
C:\> aws ec2 list-images-in-recycle-bin --image-id ami-01234567890abcdef
```

Example output:

```
{  
    "Images": [
```

```
[  
    {  
        "ImageId": "ami-0f740206c743d75df",  
        "Name": "My AL2 AMI",  
        "Description": "My Amazon Linux 2 AMI",  
        "RecycleBinEnterTime": "2021-11-26T21:04:50+00:00",  
        "RecycleBinExitTime": "2022-03-06T21:04:50+00:00"  
    }  
]
```

Important

If you receive the following error, you might need to update your AWS CLI version. For more information, see [Command not found errors](#).

```
aws.exe: error: argument operation: Invalid choice, valid choices are: ...
```

Restore AMIs from the Recycle Bin

You can't use an AMI in any way while it is in the Recycle Bin. To use the AMI, you must first restore it. When you restore an AMI from the Recycle Bin, the AMI is immediately available for use, and it is removed from the Recycle Bin. You can use a restored AMI in the same way that you use any other AMI in your account.

You can restore an AMI from the Recycle Bin using one of the following methods.

Recycle Bin console

To restore an AMI from the Recycle Bin using the console

1. Open the Recycle Bin console at console.aws.amazon.com/rbin/home/.
2. In the navigation pane, choose **Recycle Bin**.
3. The grid lists all of the resources that are currently in the Recycle Bin. Select the AMI to restore, and choose **Recover**.
4. When prompted, choose **Recover**.

AWS CLI

To restore a deleted AMI from the Recycle Bin using the AWS CLI

Use the [restore-image-from-recycle-bin](#) AWS CLI command. For `--image-id`, specify the ID of the AMI to restore.

```
C:\> aws ec2 restore-image-from-recycle-bin --image-id ami_id
```

For example, the following command restores AMI `ami-01234567890abcdef` from the Recycle Bin.

```
C:\> aws ec2 restore-image-from-recycle-bin --image-id ami-01234567890abcdef
```

The command returns no output on success.

Important

If you receive the following error, you might need to update your AWS CLI version. For more information, see [Command not found errors](#).

```
aws.exe: error: argument operation: Invalid choice, valid choices are: ...
```

Automate the EBS-backed AMI lifecycle

You can use Amazon Data Lifecycle Manager to automate the creation, retention, copy, deprecation, and deregistration of Amazon EBS-backed AMIs and their backing snapshots. For more information, see [Amazon Data Lifecycle Manager \(p. 1859\)](#).

Use encryption with EBS-backed AMIs

AMIs that are backed by Amazon EBS snapshots can take advantage of Amazon EBS encryption. Snapshots of both data and root volumes can be encrypted and attached to an AMI. You can launch instances and copy images with full EBS encryption support included. Encryption parameters for these operations are supported in all Regions where AWS KMS is available.

EC2 instances with encrypted EBS volumes are launched from AMIs in the same way as other instances. In addition, when you launch an instance from an AMI backed by unencrypted EBS snapshots, you can encrypt some or all of the volumes during launch.

Like EBS volumes, snapshots in AMIs can be encrypted by either your default AWS KMS key, or to a customer managed key that you specify. You must in all cases have permission to use the selected KMS key.

AMIs with encrypted snapshots can be shared across AWS accounts. For more information, see [Shared AMIs \(p. 129\)](#).

Encryption with EBS-backed AMIs topics

- [Instance-launching scenarios \(p. 193\)](#)
- [Image-copying scenarios \(p. 195\)](#)

Instance-launching scenarios

Amazon EC2 instances are launched from AMIs using the `RunInstances` action with parameters supplied through block device mapping, either by means of the AWS Management Console or directly using the Amazon EC2 API or CLI. For more information about block device mapping, see [Block device mapping](#). For examples of controlling block device mapping from the AWS CLI, see [Launch, List, and Terminate EC2 Instances](#).

By default, without explicit encryption parameters, a `RunInstances` action maintains the existing encryption state of an AMI's source snapshots while restoring EBS volumes from them. If [Encryption by default \(p. 1925\)](#) is enabled, all volumes created from the AMI (whether from encrypted or unencrypted snapshots) will be encrypted. If encryption by default is not enabled, then the instance maintains the encryption state of the AMI.

You can also launch an instance and simultaneously apply a new encryption state to the resulting volumes by supplying encryption parameters. Consequently, the following behaviors are observed:

Launch with no encryption parameters

- An unencrypted snapshot is restored to an unencrypted volume, unless encryption by default is enabled, in which case all the newly created volumes will be encrypted.
- An encrypted snapshot that you own is restored to a volume that is encrypted to the same KMS key.
- An encrypted snapshot that you do not own (for example, the AMI is shared with you) is restored to a volume that is encrypted by your AWS account's default KMS key.

The default behaviors can be overridden by supplying encryption parameters. The available parameters are **Encrypted** and **KmsKeyId**. Setting only the **Encrypted** parameter results in the following:

Instance launch behaviors with **Encrypted** set, but no **KmsKeyId** specified

- An unencrypted snapshot is restored to an EBS volume that is encrypted by your AWS account's default KMS key.
- An encrypted snapshot that you own is restored to an EBS volume encrypted by the same KMS key. (In other words, the **Encrypted** parameter has no effect.)
- An encrypted snapshot that you do not own (i.e., the AMI is shared with you) is restored to a volume that is encrypted by your AWS account's default KMS key. (In other words, the **Encrypted** parameter has no effect.)

Setting both the **Encrypted** and **KmsKeyId** parameters allows you to specify a non-default KMS key for an encryption operation. The following behaviors result:

Instance with both **Encrypted** and **KmsKeyId** set

- An unencrypted snapshot is restored to an EBS volume encrypted by the specified KMS key.
- An encrypted snapshot is restored to an EBS volume encrypted not to the original KMS key, but instead to the specified KMS key.

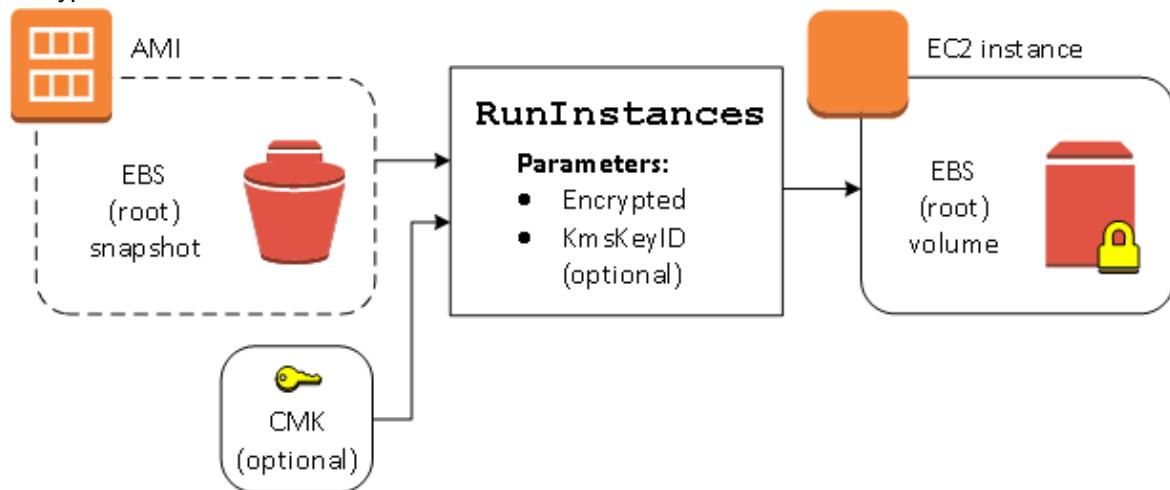

Submitting a **KmsKeyId** without also setting the **Encrypted** parameter results in an error.

The following sections provide examples of launching instances from AMIs using non-default encryption parameters. In each of these scenarios, parameters supplied to the `RunInstances` action result in a change of encryption state during restoration of a volume from a snapshot.

For information about using the console to launch an instance from an AMI, see [Launch your instance \(p. 551\)](#).

Encrypt a volume during launch

In this example, an AMI backed by an unencrypted snapshot is used to launch an EC2 instance with an encrypted EBS volume.

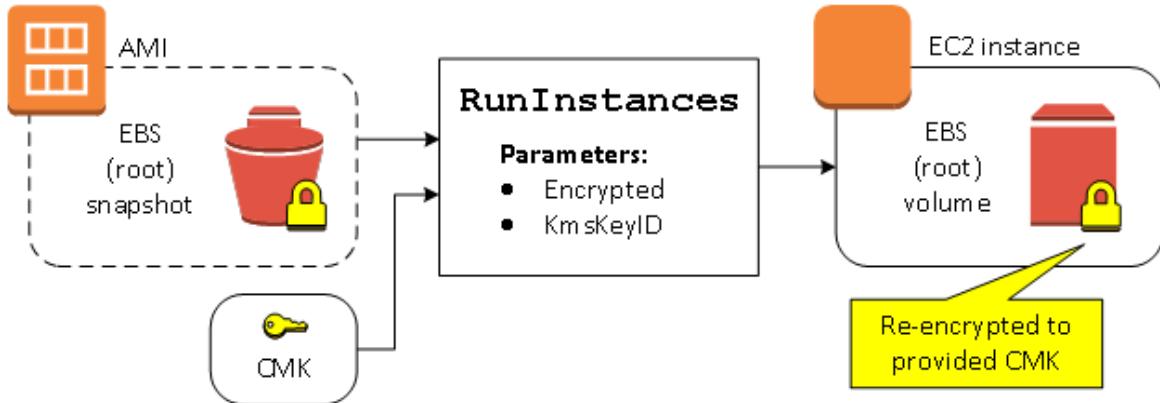

The **Encrypted** parameter alone results in the volume for this instance being encrypted. Providing a **KmsKeyId** parameter is optional. If no KMS key ID is specified, the AWS account's default KMS key is

used to encrypt the volume. To encrypt the volume to a different KMS key that you own, supply the `KmsKeyId` parameter.

Re-encrypt a volume during launch

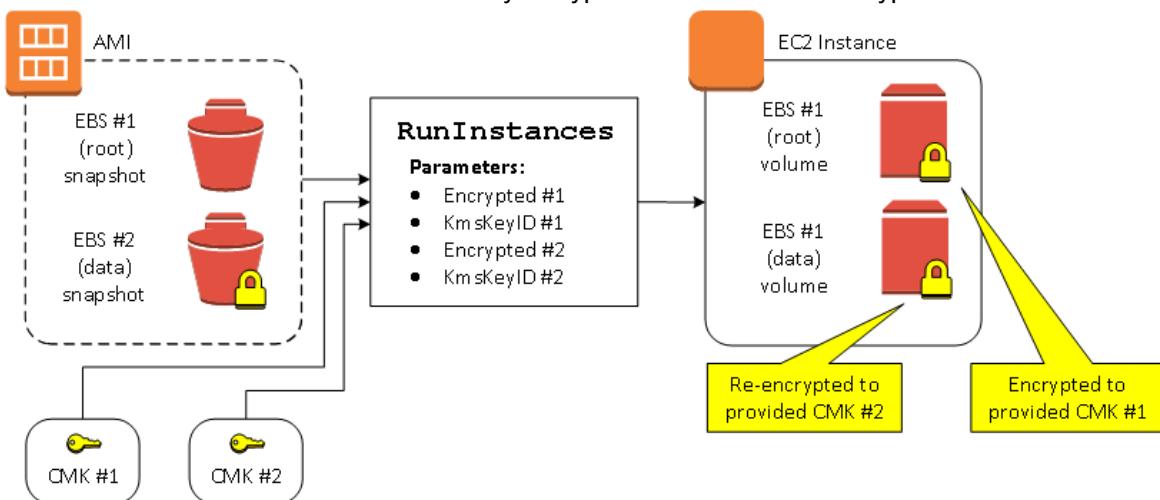

In this example, an AMI backed by an encrypted snapshot is used to launch an EC2 instance with an EBS volume encrypted by a new KMS key.

If you own the AMI and supply no encryption parameters, the resulting instance has a volume encrypted by the same KMS key as the snapshot. If the AMI is shared rather than owned by you, and you supply no encryption parameters, the volume is encrypted by your default KMS key. With encryption parameters supplied as shown, the volume is encrypted by the specified KMS key.

Change encryption state of multiple volumes during launch

In this more complex example, an AMI backed by multiple snapshots (each with its own encryption state) is used to launch an EC2 instance with a newly encrypted volume and a re-encrypted volume.

In this scenario, the `RunInstances` action is supplied with encryption parameters for each of the source snapshots. When all possible encryption parameters are specified, the resulting instance is the same regardless of whether you own the AMI.

Image-copying scenarios

Amazon EC2 AMIs are copied using the `CopyImage` action, either through the AWS Management Console or directly using the Amazon EC2 API or CLI.

By default, without explicit encryption parameters, a CopyImage action maintains the existing encryption state of an AMI's source snapshots during copy. You can also copy an AMI and simultaneously apply a new encryption state to its associated EBS snapshots by supplying encryption parameters. Consequently, the following behaviors are observed:

Copy with no encryption parameters

- An unencrypted snapshot is copied to another unencrypted snapshot, unless encryption by default is enabled, in which case all the newly created snapshots will be encrypted.
- An encrypted snapshot that you own is copied to a snapshot encrypted with the same KMS key.
- An encrypted snapshot that you do not own (that is, the AMI is shared with you) is copied to a snapshot that is encrypted by your AWS account's default KMS key.

All of these default behaviors can be overridden by supplying encryption parameters. The available parameters are Encrypted and KmsKeyId. Setting only the Encrypted parameter results in the following:

Copy-image behaviors with Encrypted set, but no KmsKeyId specified

- An unencrypted snapshot is copied to a snapshot encrypted by the AWS account's default KMS key.
- An encrypted snapshot is copied to a snapshot encrypted by the same KMS key. (In other words, the Encrypted parameter has no effect.)
- An encrypted snapshot that you do not own (i.e., the AMI is shared with you) is copied to a volume that is encrypted by your AWS account's default KMS key. (In other words, the Encrypted parameter has no effect.)

Setting both the Encrypted and KmsKeyId parameters allows you to specify a customer managed KMS key for an encryption operation. The following behaviors result:

Copy-image behaviors with both Encrypted and KmsKeyId set

- An unencrypted snapshot is copied to a snapshot encrypted by the specified KMS key.
- An encrypted snapshot is copied to a snapshot encrypted not to the original KMS key, but instead to the specified KMS key.

Submitting a KmsKeyId without also setting the Encrypted parameter results in an error.

The following section provides an example of copying an AMI using non-default encryption parameters, resulting in a change of encryption state.

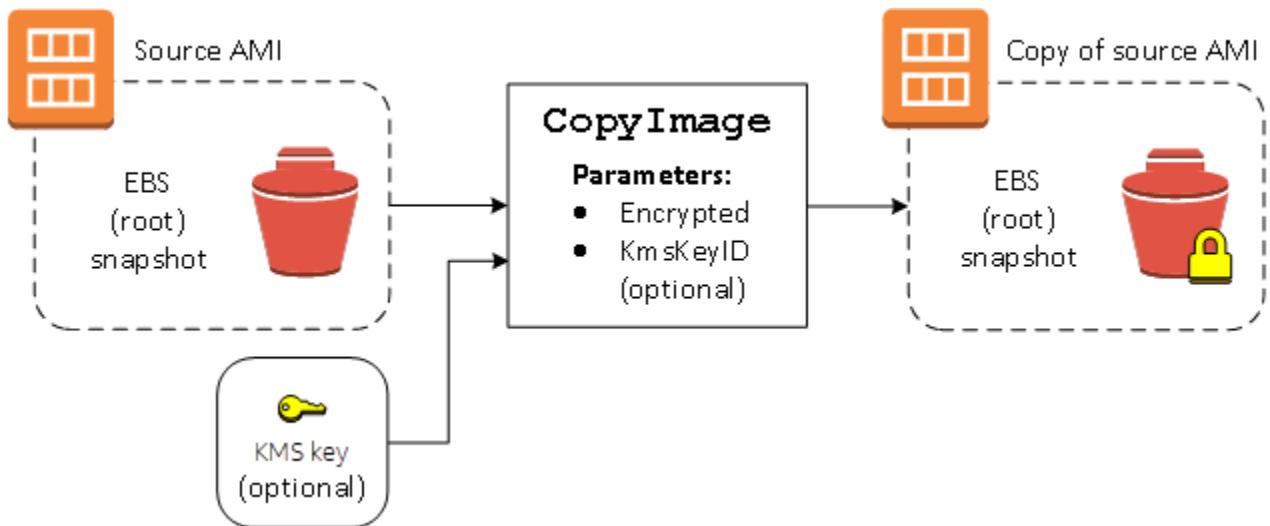

For detailed instructions using the console, see [Copy an AMI \(p. 166\)](#).

Encrypt an unencrypted image during copy

In this scenario, an AMI backed by an unencrypted root snapshot is copied to an AMI with an encrypted root snapshot. The CopyImage action is invoked with two encryption parameters, including a customer managed key. As a result, the encryption status of the root snapshot changes, so that the target AMI is backed by a root snapshot containing the same data as the source snapshot, but encrypted using the specified key. You incur storage costs for the snapshots in both AMIs, as well as charges for any instances you launch from either AMI.

Note

Enabling [encryption by default \(p. 1925\)](#) has the same effect as setting the Encrypted parameter to true for all snapshots in the AMI.

Setting the **Encrypted** parameter encrypts the single snapshot for this instance. If you do not specify the **KmsKeyId** parameter, the default customer managed key is used to encrypt the snapshot copy.

Note

You can also copy an image with multiple snapshots and configure the encryption state of each individually.

Monitor AMI events using Amazon EventBridge

When the state of an Amazon Machine Image (AMI) changes, Amazon EC2 generates an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events). You can use Amazon EventBridge to detect and react to these events. You do this by creating rules in EventBridge that trigger an action in response to an event. For example, you can create an EventBridge rule that detects when the AMI creation process has completed and then invokes an Amazon SNS topic to send an email notification to you.

Amazon EC2 generates an event when an AMI enters any of the following states:

- available
- failed
- deregistered

An AMI can enter the **available** or **failed** state when one of the following AMI operations runs:

- `CreateImage`
- `CopyImage`
- `RegisterImage`
- `CreateRestoreImageTask`

An AMI can enter the **deregistered** state when the following AMI operation runs:

- `DeregisterImage`

Events are generated on a best effort basis.

Topics

- [AMI events \(p. 198\)](#)
- [Create Amazon EventBridge rules \(p. 199\)](#)

AMI events

There are three EC2 AMI State Change events:

- [available \(p. 198\)](#)
- [failed \(p. 199\)](#)
- [deregistered \(p. 199\)](#)

The events are sent to the default EventBridge event bus in JSON format.

The following fields in the event can be used to create rules that trigger an action:

"source": "aws.ec2"

Identifies that the event is from Amazon EC2.

"detail-type": "EC2 AMI State Change"

Identifies the event name.

"detail": { "ImageId": "ami-0123456789example", "State": "available", }

Provides the following information:

- The AMI ID – If you want to track a specific AMI.
- The state of the AMI (available, failed, or deregistered).

available

The following is an example of an event that Amazon EC2 generates when the AMI enters the available state following a successful CreateImage, CopyImage, RegisterImage, or CreateRestoreImageTask operation.

"State": "available" indicates that the operation was successful.

```
{  
    "version": "0",  
    "id": "example-9f07-51db-246b-d8b8441bcdf0",  
    "detail-type": "EC2 AMI State Change",  
    "source": "aws.ec2",  
    "account": "012345678901",  
    "time": "yyyy-mm-ddThh:mm:ssZ",  
    "region": "us-east-1",  
    "resources": ["arn:aws:ec2:us-east-1::image/ami-0123456789example"],  
    "detail": {  
        "RequestId": "example-9dcc-40a6-aa77-7ce457d5442b",  
        "ImageId": "ami-0123456789example",  
        "State": "available",  
        "ErrorMessage": ""  
    }  
}
```

failed

The following is an example of an event that Amazon EC2 generates when the AMI enters the failed state following a failed CreateImage, CopyImage, RegisterImage, or CreateRestoreImageTask operation.

The following fields provide pertinent information:

- "State": "failed" – Indicates that the operation failed.
- "ErrorMessage": "" – Provides the reason for the failed operation.

```
{  
    "version": "0",  
    "id": "example-9f07-51db-246b-d8b8441bcd0",  
    "detail-type": "EC2 AMI State Change",  
    "source": "aws.ec2",  
    "account": "012345678901",  
    "time": "yyyy-mm-ddThh:mm:ssZ",  
    "region": "us-east-1",  
    "resources": ["arn:aws:ec2:us-east-1::image/ami-0123456789example"],  
    "detail": {  
        "RequestId": "example-9dcc-40a6-aa77-7ce457d5442b",  
        "ImageId": "ami-0123456789example",  
        "State": "failed",  
        "ErrorMessage": "Description of failure"  
    }  
}
```

deregistered

The following is an example of an event that Amazon EC2 generates when the AMI enters the deregistered state following a successful DeregisterImage operation. If the operation fails, no event is generated. Any failure is known immediately because DeregisterImage is a synchronous operation.

"State": "deregistered" indicates that the DeregisterImage operation was successful.

```
{  
    "version": "0",  
    "id": "example-9f07-51db-246b-d8b8441bcd0",  
    "detail-type": "EC2 AMI State Change",  
    "source": "aws.ec2",  
    "account": "012345678901",  
    "time": "yyyy-mm-ddThh:mm:ssZ",  
    "region": "us-east-1",  
    "resources": ["arn:aws:ec2:us-east-1::image/ami-0123456789example"],  
    "detail": {  
        "RequestId": "example-9dcc-40a6-aa77-7ce457d5442b",  
        "ImageId": "ami-0123456789example",  
        "State": "deregistered",  
        "ErrorMessage": ""  
    }  
}
```

Create Amazon EventBridge rules

You can create an Amazon EventBridge [rule](#) that specifies an action to take when EventBridge receives an [event](#) that matches the [event pattern](#) in the rule. When an event matches, EventBridge sends the event to the specified [target](#) and triggers the action defined in the rule.

Event patterns have the same structure as the events they match. An event pattern either matches an event or it doesn't.

When creating a rule for an AMI state change event, you can include the following fields in the event pattern:

"source": "aws.ec2"

Identifies that the event is from Amazon EC2.

"detail-type": "EC2 AMI State Change"

Identifies the event name.

"detail": { "ImageId": "ami-0123456789example", "State": "available", }

Provides the following information:

- The AMI ID – If you want to track a specific AMI.
- The state of the AMI (available, failed, or deregistered).

Example: Create an EventBridge rule to send a notification

The following example creates an EventBridge rule to send an email, text message, or mobile push notification when any AMI is in the available state after the `CreateImage` operation has completed successfully.

Before creating the EventBridge rule, you must create the Amazon SNS topic for the email, text message, or mobile push notification.

To create an EventBridge rule to send a notification when an AMI is created and in the available state

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. Choose **Create rule**.
3. For **Define rule detail**, do the following:
 - a. Enter a **Name** for the rule, and, optionally, a description.
A rule can't have the same name as another rule in the same Region and on the same event bus.
 - b. For **Event bus**, choose **default**. When an AWS service in your account generates an event, it always goes to your account's default event bus.
 - c. For **Rule type**, choose **Rule with an event pattern**.
 - d. Choose **Next**.
4. For **Build event pattern**, do the following:
 - a. For **Event source**, choose **AWS events or EventBridge partner events**.
 - b. For **Event pattern**, for this example you'll specify the following event pattern to match any EC2 AMI State Change event that is generated when an AMI enters the available state:

```
{  
  "source": ["aws.ec2"],  
  "detail-type": ["EC2 AMI State Change"],  
  "detail": {"State": ["available"]}  
}
```

To add the event pattern, you can either use a template by choosing **Event pattern form**, or specify your own pattern by choosing **Custom pattern (JSON editor)**, as follows:

- i. To use a template to create the event pattern, do the following:
 - A. Choose **Event pattern form**.
 - B. For **Event source**, choose **AWS services**.
 - C. For **AWS Service**, choose **EC2**.
 - D. For **Event type**, choose **EC2 AMI State Change**.
 - E. To customize the template, choose **Edit pattern** and make your changes to match the example event pattern.
 - ii. To specify a custom event pattern, do the following:
 - A. Choose **Custom pattern (JSON editor)**.
 - B. In the **Event pattern** box, add the event pattern for this example.
- c. Choose **Next**.
5. For **Select target(s)**, do the following:
 - a. For **Target types**, choose **AWS service**.
 - b. For **Select a target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.
 - c. For **Topic**, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see [Using Amazon SNS for application-to-person \(A2P\) messaging](#) in the *Amazon Simple Notification Service Developer Guide*.
 - d. (Optional) Under **Additional settings**, you can optionally configure additional settings. For more information, see [Creating Amazon EventBridge rules that react to events](#) (step 16) in the *Amazon EventBridge User Guide*.
 - e. Choose **Next**.
 6. (Optional) For **Tags**, you can optionally assign one or more tags to your rule, and then choose **Next**.
 7. For **Review and create**, do the following:
 - a. Review the details of the rule and modify them as necessary.
 - b. Choose **Create rule**.

For more information, see the following topics in the *Amazon EventBridge User Guide*:

- [Amazon EventBridge events](#)
- [Amazon EventBridge event patterns](#)
- [Amazon EventBridge rules](#)

For a tutorial on how to create a Lambda function and an EventBridge rule that runs the Lambda function, see [Tutorial: Log the state of an Amazon EC2 instance using EventBridge](#) in the *AWS Lambda Developer Guide*.

Understand AMI billing information

There are many Amazon Machine Images (AMIs) to choose from when launching your instances, and they support a variety of operating system platforms and features. To understand how the AMI you choose when launching your instance affects the bottom line on your AWS bill, you can research the associated operating system platform and billing information. Do this before you launch any On-Demand or Spot Instances, or purchase a Reserved Instance.

Here are two examples of how researching your AMI in advance can help you choose the AMI that best suits your needs:

- For Spot Instances, you can use the AMI **Platform details** to confirm that the AMI is supported for Spot Instances.
- When purchasing a Reserved Instance, you can make sure that you select the operating system platform (**Platform**) that maps to the AMI **Platform details**.

For more information about instance pricing, see [Amazon EC2 pricing](#).

Contents

- [AMI billing information fields \(p. 202\)](#)
- [Finding AMI billing and usage details \(p. 203\)](#)
- [Verify AMI charges on your bill \(p. 205\)](#)

AMI billing information fields

The following fields provide billing information associated with an AMI:

Platform details

The platform details associated with the billing code of the AMI. For example, Red Hat Enterprise Linux.

Usage operation

The operation of the Amazon EC2 instance and the billing code that is associated with the AMI. For example, RunInstances:0010. **Usage operation** corresponds to the [lineitem/Operation](#) column on your AWS Cost and Usage Report (CUR) and in the [AWS Price List API](#).

You can view these fields on the **Instances** or **AMIs** page in the Amazon EC2 console, or in the response that is returned by the [describe-images](#) or [Get-EC2Image](#) command.

Sample data: usage operation by platform

The following table lists some of the platform details and usage operation values that can be displayed on the **Instances** or **AMIs** pages in the Amazon EC2 console, or in the response that is returned by the [describe-images](#) or [Get-EC2Image](#) command.

Platform details	Usage operation **
Linux/UNIX	RunInstances
Red Hat BYOL Linux	RunInstances:00g0
Red Hat Enterprise Linux	RunInstances:0010
Red Hat Enterprise Linux with HA	RunInstances:1010
Red Hat Enterprise Linux with SQL Server Standard and HA	RunInstances:1014
Red Hat Enterprise Linux with SQL Server Enterprise and HA	RunInstances:1110

Platform details	Usage operation **
Red Hat Enterprise Linux with SQL Server Standard	RunInstances:0014
Red Hat Enterprise Linux with SQL Server Web	RunInstances:0210
Red Hat Enterprise Linux with SQL Server Enterprise	RunInstances:0110
SQL Server Enterprise	RunInstances:0100
SQL Server Standard	RunInstances:0004
SQL Server Web	RunInstances:0200
SUSE Linux	RunInstances:000g
Ubuntu Pro	RunInstances:0g00
Windows	RunInstances:0002
Windows BYOL	RunInstances:0800
Windows with SQL Server Enterprise *	RunInstances:0102
Windows with SQL Server Standard *	RunInstances:0006
Windows with SQL Server Web *	RunInstances:0202

* If two software licenses are associated with an AMI, the **Platform details** field shows both.

** If you are running Spot Instances, the [lineitem/Operation](#) on your AWS Cost and Usage Report might be different from the **Usage operation** value that is listed here. For example, if [lineitem/Operation](#) displays RunInstances : 0010 : SV006, it means that Amazon EC2 is running Red Hat Enterprise Linux Spot Instance-hour in US East (Virginia) in VPC Zone #6.

Finding AMI billing and usage details

In the Amazon EC2 console, you can view the AMI billing information from the **AMIs** page or from the **Instances** page. You can also find billing information using the AWS CLI or the instance metadata service.

The following fields can help you verify AMI charges on your bill:

- **Platform details**
- **Usage operation**
- **AMI ID**

Find AMI billing information (console)

Follow these steps to view AMI billing information in the Amazon EC2 console:

Look up AMI billing information from the AMIs page

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **AMIs**, and then select an AMI.
3. On the **Details** tab, check the values for **Platform details** and **Usage operation**.

Look up AMI billing information from the Instances page

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, and then select an instance.
3. On the **Details** tab (or the **Description** tab if you are using the prior version of the console), check the values for **Platform details** and **Usage operation**.

Find AMI billing information (AWS CLI)

To find the AMI billing information using the AWS CLI, you need to know the AMI ID. If you don't know the AMI ID, you can get it from the instance using the [describe-instances](#) command.

To find the AMI ID

If you know the instance ID, you can get the AMI ID for the instance by using the [describe-instances](#) command.

```
aws ec2 describe-instances --instance-ids i-123456789abcde123
```

In the output, the AMI ID is specified in the `ImageId` field.

```
... "Instances": [  
{  
    "AmiLaunchIndex": 0,  
    "ImageId": "ami-0123456789EXAMPLE",  
    "InstanceId": "i-123456789abcde123",  
    ...  
}]
```

To find the AMI billing information

If you know the AMI ID, you can use the [describe-images](#) command to get the AMI platform and usage operation details.

```
$ aws ec2 describe-images --image-ids ami-0123456789EXAMPLE
```

The following example output shows the `PlatformDetails` and `UsageOperation` fields. In this example, the `ami-0123456789EXAMPLE` platform is Red Hat Enterprise Linux and the usage operation and billing code is `RunInstances:0010`.

```
{  
    "Images": [  
        {  
            "VirtualizationType": "hvm",  
            "Description": "Provided by Red Hat, Inc.",  
            "Hypervisor": "xen",  
            "EnaSupport": true,  
            "SriovNetSupport": "simple",  
            "ImageId": "ami-0123456789EXAMPLE",  
            "State": "available",  
            "BlockDeviceMappings": [  
                {  
                    "DeviceName": "/dev/sda1",  
                    "Ebs": {  
                        "SnapshotId": "snap-111222333444aaabb",  
                        "DeleteOnTermination": true,  
                        "VolumeType": "gp2",  
                    }  
                }  
            ]  
        }  
    ]  
}
```

```
        "VolumeSize": 10,
        "Encrypted": false
    }
],
"Architecture": "x86_64",
"ImageLocation": "123456789012/RHEL-8.0.0_HVM-20190618-x86_64-1-Hourly2-GP2",
"RootDeviceType": "ebs",
"OwnerId": "123456789012",
"PlatformDetails": "Red Hat Enterprise Linux",

```

Verify AMI charges on your bill

To ensure that you're not incurring unplanned costs, you can verify that the billing information for an instance in your AWS Cost and Usage Report (CUR) matches the billing information that's associated with the AMI that you used to launch the instance.

To verify the billing information, find the instance ID in your CUR and check the corresponding value in the [lineitem/Operation](#) column. That value should match the value for **Usage operation** that's associated with the AMI.

For example, the AMI ami-0123456789EXAMPLE has the following billing information:

- **Platform details** = Red Hat Enterprise Linux
- **Usage operation** = RunInstances:0010

If you launched an instance using this AMI, you can find the instance ID in your CUR, and check the corresponding value in the [lineitem/Operation](#) column. In this example, the value should be RunInstances:0010.

AMI quotas

The following quotas apply to creating and sharing AMIs. The quotas apply per AWS Region.

Quota name	Description	Default quota per Region
AMIs	The maximum number of public and private AMIs allowed per Region. These include available and pending AMIs, and AMIs in the Recycle Bin.	50,000
Public AMIs	The maximum number of public AMIs, including public AMIs in the Recycle Bin, allowed per Region.	5

Quota name	Description	Default quota per Region
AMI sharing	The maximum number of entities (organizations, organizational units (OUs), and accounts) that an AMI can be shared with in a Region. Note that if you share an AMI with an organization or OU, the number of accounts in the organization or OU does not count towards the quota.	1,000

If you exceed your quotas and you want to create or share more AMIs, you can do the following:

- If you exceed your total AMIs or public AMIs quota, consider deregistering unused images.
- If you exceed your public AMIs quota, consider making one or more public AMIs private.
- If you exceed your AMI sharing quota, consider sharing your AMIs with an organization or OU instead of separate accounts.
- Request a quota increase for AMIs.

Request a quota increase for AMIs

If you need more than the default quota for AMIs, you can request a quota increase.

To request a quota increase for AMIs

1. Open the Service Quotas console at <https://console.aws.amazon.com/servicequotas/home>.
2. In the navigation pane, choose **AWS services**.
3. Choose **Amazon Elastic Compute Cloud (Amazon EC2)** from the list, or type the name of the service in the search box.
4. Choose the AMI quota to request an increase. The AMI quotas you can select are:
 - AMIs
 - Public AMIs
 - AMI sharing
5. Choose **Request quota increase**.
6. For **Change quota value**, enter the new quota value, and then choose **Request**.

To view any pending or recently resolved requests, choose **Dashboard** from the navigation pane. For pending requests, choose the status of the request to open the request receipt. The initial status of a request is **Pending**. After the status changes to **Quota requested**, you'll see the case number under **Support Center case number**. Choose the case number to open the ticket for your request.

After the request is resolved, the **Applied quota value** for the quota is set to the new value.

For more information, see the [Service Quotas User Guide](#).

Amazon EC2 instances

If you're new to Amazon EC2, see the following topics to get started:

- [What is Amazon EC2? \(p. 1\)](#)
- [Set up to use Amazon EC2 \(p. 7\)](#)
- [Tutorial: Get started with Amazon EC2 Windows instances \(p. 14\)](#)
- [Instance lifecycle \(p. 546\)](#)

Before you launch a production environment, you need to answer the following questions.

Q. What instance type best meets my needs?

Amazon EC2 provides different instance types to enable you to choose the CPU, memory, storage, and networking capacity that you need to run your applications. For more information, see [Instance types \(p. 210\)](#).

Q. What purchasing option best meets my needs?

Amazon EC2 supports On-Demand Instances (the default), Spot Instances, and Reserved Instances. For more information, see [Instance purchasing options \(p. 349\)](#).

Q. Can I remotely manage a fleet of EC2 instances and machines in my hybrid environment?

AWS Systems Manager enables you to remotely and securely manage the configuration of your Amazon EC2 instances, and your on-premises instances and virtual machines (VMs) in hybrid environments, including VMs from other cloud providers. For more information, see the [AWS Systems Manager User Guide](#).

Amazon EC2 Windows instances

The following is an introduction to key components of Amazon EC2 and how a Windows instance compares to running Windows Server on premises.

Instances and AMIs

An *Amazon Machine Image (AMI)* is a template that contains a software configuration (for example, an operating system, an application server, and applications). From an AMI, you launch *instances*, which are copies of the AMI running as virtual servers in the cloud.

Amazon publishes many AMIs that contain common software configurations for public use. In addition, members of the AWS developer community have published their own custom AMIs. You can also create your own custom AMIs. Doing so enables you to quickly and easily start new instances that have everything you need. For example, if your application is a website or web service, your AMI could include a web server, the associated static content, and the code for the dynamic pages. As a result, after you launch an instance from this AMI, your web server starts, and your application is ready to accept requests.

To improve launch time for Windows instances, you can optimize your AMI for faster launching, which creates a set of pre-provisioned snapshots to launch instances up to 65% faster. To learn more, see [Configure your Windows AMI for faster launching \(p. 43\)](#).

You can launch different types of instances from a single AMI. An *instance type* determines the infrastructure that is used for your instance. Some instance types are intended for general purpose use,

while others support optimizations for specific uses such as high performance processors for computing, enhanced memory for processing large data sets, and fast I/O for storage. Select an instance type that delivers the performance and size that you need for the applications or software that you plan to run on the instance. For more information, see [Amazon EC2 Instance Types](#).

Your Windows instances keep running until you stop or terminate them, or until they fail. If an instance fails, you can launch a new one from the AMI.

Your AWS account has a limit on the number of instances that you can have running. For more information about this limit, and how to request an increase, see [How many instances can I run in Amazon EC2](#) in the Amazon EC2 General FAQ.

Differences between Windows Server and Windows instances

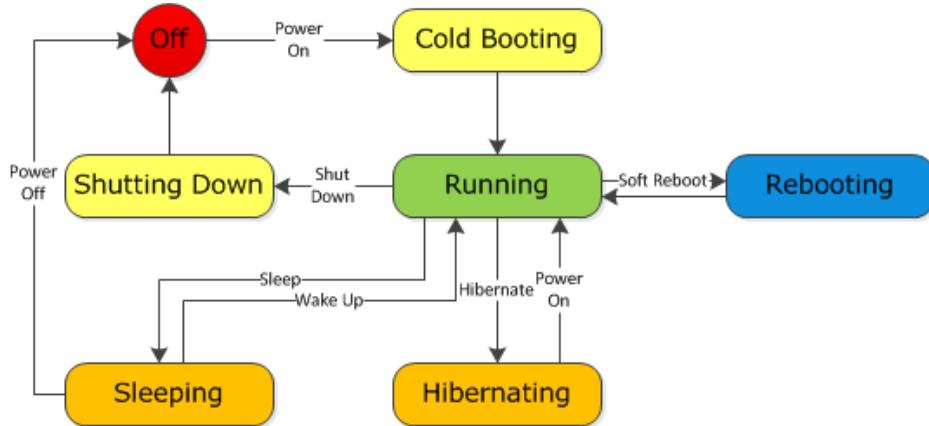

After you launch your Amazon EC2 Windows instance, it behaves like a traditional server running Windows Server. For example, both Windows Server and an Amazon EC2 instance can be used to run your web applications, conduct batch processing, or manage applications requiring large-scale computations. However, there are important differences between the server hardware model and the cloud computing model. The way an Amazon EC2 instance runs is not the same as the way a traditional server running Windows Server runs.

Before you begin launching Amazon EC2 Windows instances, you should be aware that the architecture of applications running on cloud servers can differ significantly from the architecture for traditional application models running on your hardware. Implementing applications on cloud servers requires a shift in your design process.

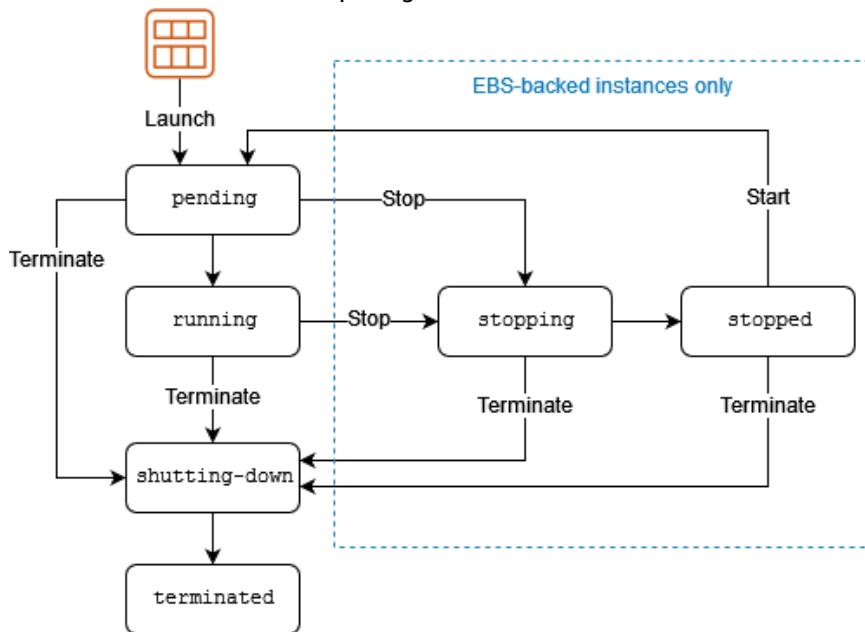

The following table describes some key differences between Windows Server and an Amazon EC2 Windows instance.

Windows Server	Amazon EC2 Windows Instance
Resources and capacity are physically limited.	Resources and capacity are scalable.
You pay for the infrastructure, even if you don't use it.	You pay for the usage of the infrastructure. We stop charging you for the instance as soon as you stop or terminate it.
Occupies physical space and must be maintained on a regular basis.	Doesn't occupy physical space and does not require regular maintenance.
Starts with push of the power button (known as <i>cold booting</i>).	Starts with the launch of the instance.
You can keep the server running until it is time to shut it down, or put it in a sleep or hibernation state (during which the server is powered down).	You can keep the server running, or stop and restart it (during which the instance is moved to a new host computer).
When you shut down the server, all resources remain intact and in the state they were in when you switched it off. Information you stored on the hard drives persists and can be accessed whenever it's needed. You can restore the server to the running state by powering it on.	When you terminate the instance, its infrastructure is no longer available to you. You can't connect to or restart an instance after you've terminated it. However, you can create an image from your instance while it's running, and launch new instances from the image at any time.

A traditional server running Windows Server goes through the states shown in the following diagram.

An Amazon EC2 Windows instance is similar to the traditional Windows Server, as you can see by comparing the following diagram with the previous diagram for Windows Server. After you launch an instance, it briefly goes into the pending state while registration takes place, then it goes into the running state. The instance remains active until you stop or terminate it. You can't restart an instance after you terminate it. You can create a backup image of your instance while it's running, and launch a new instance from that backup image.

Design your applications to run on Windows instances

It is important that you consider the differences mentioned in the previous section when you design your applications to run on Amazon EC2 Windows instances.

Applications built for Amazon EC2 use the underlying computing infrastructure on an as-needed basis. They draw on necessary resources (such as storage and computing) on demand in order to perform a job, and relinquish the resources when done. In addition, they often dispose of themselves after the job is done. While in operation, the application scales up and down elastically based on resource requirements. An application running on an Amazon EC2 instance can terminate and recreate the various components at will in case of infrastructure failures.

When designing your Windows applications to run on Amazon EC2, you can plan for rapid deployment and rapid reduction of compute and storage resources, based on your changing needs.

When you run an Amazon EC2 Windows instance, you don't need to provision the exact system package of hardware, software, and storage, the way you do with Windows Server. Instead, you can focus on using a variety of cloud resources to improve the scalability and overall performance of your Windows application.

With Amazon EC2, designing for failure and outages is an integral and crucial part of the architecture. As with any scalable and redundant system, architecture of your system should account for computing, network, and storage failures. You have to build mechanisms in your applications that can handle different kinds of failures. The key is to build a modular system with individual components that are not tightly coupled, can interact asynchronously, and treat one another as black boxes that are independently scalable. Thus, if one of your components fails or is busy, you can launch more instances of that component without breaking your current system.

Another key element to designing for failure is to distribute your application geographically. Replicating your application across geographically distributed Regions improves high availability in your system.

Amazon EC2 infrastructure is programmable and you can use scripts to automate the deployment process, to install and configure software and applications, and to bootstrap your virtual servers.

You should implement security in every layer of your application architecture running on an Amazon EC2 Windows instance. If you are concerned about storing sensitive and confidential data within your Amazon EC2 environment, you should encrypt the data before uploading it.

Instance types

When you launch an instance, the *instance type* that you specify determines the hardware of the host computer used for your instance. Each instance type offers different compute, memory, and storage capabilities, and is grouped in an instance family based on these capabilities. Select an instance type based on the requirements of the application or software that you plan to run on your instance.

Amazon EC2 dedicates some resources of the host computer, such as CPU, memory, and instance storage, to a particular instance. Amazon EC2 shares other resources of the host computer, such as the network and the disk subsystem, among instances. If each instance on a host computer tries to use as much of one of these shared resources as possible, each receives an equal share of that resource. However, when a resource is underused, an instance can consume a higher share of that resource while it's available.

Each instance type provides higher or lower minimum performance from a shared resource. For example, instance types with high I/O performance have a larger allocation of shared resources. Allocating a larger share of shared resources also reduces the variance of I/O performance. For most applications, moderate I/O performance is more than enough. However, for applications that require greater or more consistent I/O performance, consider an instance type with higher I/O performance.

Instance type naming convention

Amazon EC2 provides a variety of instance types so you can choose the type that best meets your requirements. Instance types are named based on their family, generation, processor family, additional capabilities, and size. The first position of the instance type name indicates the instance family, for example c. The second position indicates the instance generation, for example 7. The third position indicates the processor family, for example g. The remaining letters before the period indicate additional capabilities, such as instance store volumes. After the period (.) is the instance size, such as small or 4xlarge, or metal for bare metal instances.

Instance families

- **C** – Compute optimized
- **D** – Dense storage
- **F** – FPGA
- **G** – Graphics intensive
- **Hpc** – High performance computing
- **I** – Storage optimized
- **Inf** – AWS Inferentia
- **M** – General purpose
- **Mac** – macOS
- **P** – GPU accelerated
- **R** – Memory optimized
- **T** – Burstable performance
- **Trn** – AWS Trainium
- **U** – High memory
- **VT** – Video transcoding
- **X** – Memory intensive

Processor families

- **a** – AMD processors

- **g** – AWS Graviton processors
- **i** – Intel processors

Additional capabilities

- **d** – Instance store volumes
- **n** – Network and EBS optimized
- **e** – Extra storage or memory
- **z** – High performance
- **flex** – Flex instance

Available instance types

Amazon EC2 provides a wide selection of instance types optimized to fit different use cases. Instance types comprise varying combinations of CPU, memory, storage, and networking capacity and give you the flexibility to choose the appropriate mix of resources for your applications. Each instance type includes one or more instance sizes, allowing you to scale your resources to the requirements of your target workload.

Note

Previous generation instances are still fully supported and retain the same features and functionality. We encourage you to use the latest generation of instances to get the best performance.

To determine which instance types meet your requirements, such as supported Regions, compute resources, or storage resources, see [Find an Amazon EC2 instance type \(p. 340\)](#).

Topics

- [Current generation instances \(p. 212\)](#)
- [Previous generation instances \(p. 217\)](#)

Current generation instances

For the best performance, we recommend that you use the following instance types when you launch new instances. For more information, see [Amazon EC2 Instance Types](#).

Sixth and seventh generation of Amazon EC2 instances

Sixth and seventh generation instances include:

- **General purpose:** M6a, M6g, M6gd, M6i, M6id, M6idn, M6in, M7g, M7i, M7i-flex, T4g
- **Compute optimized:** C6a, C6g, C6gd, C6gn, C6i, C6id, C6in, C7g, Hpc6a
- **Memory optimized:** Hpc6id, R6a, R6g, R6gd, R6i, R6id, R6idn, R6in, R7g, X2gd, X2idn, X2iedn
- **Storage optimized:** I4g, I4i, Im4gn, Is4gen
- **Accelerated computing:** G5g, Inf2, Trn1, Trn1n

Instances

- [General purpose \(p. 213\)](#)
- [Compute optimized \(p. 214\)](#)
- [Memory optimized \(p. 214\)](#)

- [Storage optimized \(p. 216\)](#)
- [Accelerated computing \(p. 216\)](#)

P3dn	p3dn.24xlarge

Previous generation instances

Amazon Web Services offers previous generation instance types for users who have optimized their applications around them and have yet to upgrade. We encourage you to use current generation instance types to get the best performance, but we continue to support the following previous generation instance types. For more information about which current generation instance type would be a suitable upgrade, see [Previous Generation Instances](#).

Type	Sizes
C1	c1.medium c1.xlarge
C3	c3.large c3.xlarge c3.2xlarge c3.4xlarge c3.8xlarge
C4	c4.large c4.xlarge c4.2xlarge c4.4xlarge c4.8xlarge
G2	g2.2xlarge g2.8xlarge
I2	i2.xlarge i2.2xlarge i2.4xlarge i2.8xlarge
M1	m1.small m1.medium m1.large m1.xlarge
M2	m2.xlarge m2.2xlarge m2.4xlarge
M3	m3.medium m3.large m3.xlarge m3.2xlarge
M4	m4.large m4.xlarge m4.2xlarge m4.4xlarge m4.10xlarge m4.16xlarge
R3	r3.large r3.xlarge r3.2xlarge r3.4xlarge r3.8xlarge
R4	r4.large r4.xlarge r4.2xlarge r4.4xlarge r4.8xlarge r4.16xlarge
T1	t1.micro

Hardware specifications

For more information, see [Amazon EC2 Instance Types](#).

To determine which instance type best meets your needs, we recommend that you launch an instance and use your own benchmark application. Because you pay by the instance second, it's convenient and inexpensive to test multiple instance types before making a decision. If your needs change, even after you make a decision, you can change the instance type later. For more information, see [Change the instance type \(p. 344\)](#).

Processor features

Intel processor features

Amazon EC2 instances that run on Intel processors may include the following features. Not all of the following processor features are supported by all instance types. For detailed information about which features are available for each instance type, see [Amazon EC2 Instance Types](#).

- **Intel AES New Instructions (AES-NI)** — Intel AES-NI encryption instruction set improves upon the original Advanced Encryption Standard (AES) algorithm to provide faster data protection and greater security. All current generation EC2 instances support this processor feature.
- **Intel Advanced Vector Extensions (Intel AVX, Intel AVX2, and Intel AVX-512)** — Intel AVX and Intel AVX2 are 256-bit, and Intel AVX-512 is a 512-bit instruction set extension designed for applications that are Floating Point (FP) intensive. Intel AVX instructions improve performance for applications like image and audio/video processing, scientific simulations, financial analytics, and 3D modeling and analysis. These features are only available on instances launched with HVM AMIs.
- **Intel Turbo Boost Technology** — Intel Turbo Boost Technology processors automatically run cores faster than the base operating frequency.
- **Intel Deep Learning Boost (Intel DL Boost)** — Accelerates AI deep learning use cases. The 2nd Gen Intel Xeon Scalable processors extend Intel AVX-512 with a new Vector Neural Network Instruction (VNNI/INT8) that significantly increases deep learning inference performance over previous generation Intel Xeon Scalable processors (with FP32) for image recognition/segmentation, object detection, speech recognition, language translation, recommendation systems, reinforcement learning, and more. VNNI may not be compatible with all Linux distributions.

The following instances support VNNI: M5n, R5n, M5dn, M5zn, R5b, R5dn, D3, D3en, and C6i. C5 and C5d instances support VNNI for only 12xlarge, 24xlarge, and metal instances.

Confusion may result from industry naming conventions for 64-bit CPUs. Chip manufacturer Advanced Micro Devices (AMD) introduced the first commercially successful 64-bit architecture based on the Intel x86 instruction set. Consequently, the architecture is widely referred to as AMD64 regardless of the chip manufacturer. Windows and several Linux distributions follow this practice. This explains why the internal system information on an instance running Ubuntu or Windows displays the CPU architecture as AMD64 even though the instances are running on Intel hardware.

Instances built on the Nitro System

The Nitro System is a collection of hardware and software components built by AWS that enable high performance, high availability, and high security. For more information, see [AWS Nitro System](#).

The Nitro System provides bare metal capabilities that eliminate virtualization overhead and support workloads that require full access to host hardware. Bare metal instances are well suited for the following:

- Workloads that require access to low-level hardware features (for example, Intel VT) that are not available or fully supported in virtualized environments
- Applications that require a non-virtualized environment for licensing or support

Nitro components

The following components are part of the Nitro System:

- Nitro card
 - Local NVMe storage volumes
 - Networking hardware support
 - Management
 - Monitoring
 - Security
- Nitro security chip, integrated into the motherboard
- Nitro hypervisor - A lightweight hypervisor that manages memory and CPU allocation and delivers performance that is indistinguishable from bare metal for most workloads.

Virtualized instances

The following virtualized instances are built on the Nitro System:

- **General purpose:** M5, M5a, M5ad, M5d, M5dn, M5n, M5zn, M6a, M6i, M6id, M6idn, M6in, M7a, M7i, M7i-flex, T3, and T3a
- **Compute optimized:** C5, C5a, C5ad, C5d, C5n, C6a, C6i, C6id, C6in, and Hpc7a
- **Memory optimized:** Hpc6id, R5, R5a, R5ad, R5b, R5d, R5dn, R5n, R6a, R6i, R6idn, R6in, R6id, U-3tb1, U-6tb1, U-9tb1, U-12tb1, U-18tb1, U-24tb1, X2idn, X2iedn, X2iezn, and z1d
- **Storage optimized:** D3, D3en, I3en, and I4i
- **Accelerated computing:** G4ad, G4dn, G5, and P3dn

Bare metal instances

The following bare metal instances are built on the Nitro System:

- **General purpose:** m5.metal | m5d.metal | m5dn.metal | m5n.metal | m5zn.metal | m6a.metal | m6i.metal | m6id.metal | m6idn.metal | m6in.metal | m7a.metal-48x1
- **Compute optimized:** c5.metal | c5d.metal | c5n.metal | c6a.metal | c6i.metal | c6id.metal | c6in.metal
- **Memory optimized:** r5.metal | r5b.metal | r5d.metal | r5dn.metal | r5n.metal | r6a.metal | r6i.metal | r6idn.metal | r6in.metal | r6id.metal | u-6tb1.metal | u-9tb1.metal | u-12tb1.metal | u-18tb1.metal | u-24tb1.metal | x2idn.metal | x2iedn.metal | x2iezn.metal | z1d.metal
- **Storage optimized:** i3.metal | i3en.metal | i4i.metal
- **Accelerated computing:** g4dn.metal

Networking and storage features

When you select an instance type, this determines the networking and storage features that are available. To describe an instance type, use the [describe-instance-types](#) command.

Networking features

- IPv6 is supported on all current generation instance types and the C3, R3, and I2 previous generation instance types.
- To maximize the networking and bandwidth performance of your instance type, you can do the following:
 - Launch supported instance types into a cluster placement group to optimize your instances for high performance computing (HPC) applications. Instances in a common cluster placement group

can benefit from high-bandwidth, low-latency networking. For more information, see [Placement groups \(p. 1352\)](#).

- Enable enhanced networking for supported current generation instance types to get significantly higher packet per second (PPS) performance, lower network jitter, and lower latencies. For more information, see [Enhanced networking on Windows \(p. 1326\)](#).
- Current generation instance types that are enabled for enhanced networking have the following networking performance attributes:
 - Traffic within the same Region over private IPv4 or IPv6 can support 5 Gbps for single-flow traffic and up to 25 Gbps for multi-flow traffic (depending on the instance type).
 - Traffic to and from Amazon S3 buckets within the same Region over the public IP address space or through a VPC endpoint can use all available instance aggregate bandwidth.
 - The maximum transmission unit (MTU) supported varies across instance types. All Amazon EC2 instance types support standard Ethernet V2 1500 MTU frames. All current generation instances support 9001 MTU, or jumbo frames, and some previous generation instances support them as well. For more information, see [Network maximum transmission unit \(MTU\) for your EC2 instance \(p. 1368\)](#).

Storage features

- Some instance types support EBS volumes and instance store volumes, while other instance types support only EBS volumes. Some instance types that support instance store volumes use solid state drives (SSD) to deliver very high random I/O performance. Some instance types support NVMe instance store volumes. Some instance types support NVMe EBS volumes. For more information, see [Amazon EBS and NVMe on Windows instances \(p. 1939\)](#) and [NVMe SSD volumes \(p. 2012\)](#).
- To obtain additional, dedicated capacity for Amazon EBS I/O, you can launch some instance types as EBS-optimized instances. Some instance types are EBS-optimized by default. For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).

Summary of networking and storage features

The following table summarizes the networking and storage features supported by current generation instance types.

Instances

- [General purpose \(p. 220\)](#)
- [Compute optimized \(p. 221\)](#)

R3	No	No	SSD	Yes	Not supported
R4	Yes	No	No	Yes	ENA
T1	Yes	No	No	Yes	Not supported

Instance limits

There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types.

For more information about the default limits, see [How many instances can I run in Amazon EC2?](#)

For more information about viewing your current limits or requesting an increase in your current limits, see [Amazon EC2 service quotas \(p. 2100\)](#).

General purpose instances

General purpose instances provide a balance of compute, memory, and networking resources, and can be used for a wide range of workloads.

M5 and M5a instances

These instances provide an ideal cloud infrastructure, offering a balance of compute, memory, and networking resources for a broad range of applications that are deployed in the cloud. They are well-suited for the following:

- Small and midsize databases
- Data processing tasks that require additional memory
- Caching fleets
- Backend servers for SAP, Microsoft SharePoint, cluster computing, and other enterprise applications

For more information, see [Amazon EC2 M5 Instances](#).

Bare metal instances, such as `m5.metal`, `m5n.meta1`, and `m5zn.metal` provide your applications with direct access to physical resources of the host server, such as processors and memory.

M5zn

These instances are ideal for applications that benefit from extremely high single-thread performance, high throughput, and low latency networking. They are well-suited for the following:

- Gaming
- High performance computing

- Simulation modeling

For more information, see [Amazon EC2 M5 Instances](#).

M6i and M6id instances

These instances are well suited for general-purpose workloads such as the following:

- Application servers and web servers
- Microservices
- High performance computing
- App development
- Small and midsize databases
- Caching fleets

Bare metal instances such as m6i.metal provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 M6i Instances](#).

M6in and M6idn instances

These instances are well suited for network-intensive workloads such as the following:

- High-performance file systems
- Distributed web scale in-memory caches
- Caching fleets
- Real-time big data analytics
- Telco applications such as 5G User Plane Function (UPF)

For more information, see [Amazon EC2 M6i Instances](#).

M7i instances

M7i instances expand the seventh generation Amazon EC2 instance portfolio to include x86-based options. These instances are powered by custom 4th generation Intel Xeon Scalable Processors (Sapphire Rapids) that are exclusive to AWS. They deliver up to 15 percent improvement in price-performance compared to M6i instances. M7i instances are a good fit for running general-purpose workloads, such as web-servers, application servers, micro-services, and small data stores.

For more information, see [Amazon EC2 M7i instances](#).

M7i-flex instances

A majority of general-purpose workloads benefit from the latest generation performance but do not fully utilize the compute resources. Amazon EC2 flex instances are an ideal first choice to run such workloads. Flex instances are cost-optimized variants of Amazon EC2 instances that provide the easiest way for you to get price performance benefits and lower prices for a majority of common workloads.

M7i-flex instances are the first Amazon EC2 flex instances that are based on the 4th generation Intel Xeon Scalable processors (Sapphire Rapids), and can save costs when compared to equivalent M instances. M7i-flex instances offer up to 32 vCPUs and up to 128 GiB of memory to deliver a balance of compute, memory, and networking resources. These instances are well suited for general purpose workloads such as the following:

- Application servers and web servers
- Microservices
- Virtual desktops
- App development
- Databases
- Mobile applications
- Batch workloads

For more information, see [Amazon EC2 M7i and M7i-flex instances](#).

M7g and M7gd instances

These instances are powered by AWS Graviton3 processors and deliver balanced compute, memory, and networking for a broad range of general purpose workloads. They are well suited for the following:

- Application servers
- Microservices
- Gaming servers
- Midsize data stores
- Caching fleets

For more information, see [Amazon EC2 M7g instances](#).

M7a instances

M7a instances are built on the AWS Nitro System and are ideal for applications that benefit from high performance and high throughput, low latency networking, such as application servers, microservices, gaming servers, mid-size data stores, application development environments, and caching fleets.

For more information, see [Amazon EC2 M7a Instances](#).

T2, T3, and T3a instances

These instances provide a baseline level of CPU performance with the ability to burst to a higher level when required by your workload. An Unlimited instance can sustain high CPU performance for any period of time whenever required. For more information, see [Burstable performance instances \(p. 245\)](#). They are well-suited for the following:

- Websites and web applications
- Code repositories
- Development, build, test, and staging environments
- Microservices

For more information, see [Amazon EC2 T2 Instances](#) and [Amazon EC2 T3 Instances](#).

Hardware specifications

The following is a summary of the hardware specifications for general purpose instances. A virtual central processing unit (vCPU) represents a portion of the physical CPU assigned to a virtual machine (VM). For x86 instances, there are two vCPUs per core. For Graviton instances, there is one vCPU per core.

Instance type	Default vCPUs	Memory (GiB)

The general purpose instances use the following processors.

AMD processors

- **AMD EPYC 7000 series processors (AMD EPYC 7571):** M5a, M5ad, T3a
- **3rd generation AMD EPYC processors (AMD EPYC 7R13):** M6a
- **4th generation AMD EPYC processors (AMD EPYC 9R14):** M7a

Intel processors

- **Intel Xeon Scalable processors (Haswell E5-2676 v3 or Broadwell E5-2686 v4):** M4, T2
- **Intel Xeon Scalable processors (Skylake 8175M or Cascade Lake 8259CL):** M5, M5d, T3
- **2nd generation Intel Xeon Scalable processors (Cascade Lake 8259CL):** M5n
- **2nd generation Intel Xeon Scalable processors (Cascade Lake 8252C):** M5zn
- **3rd generation Intel Xeon Scalable processors (Ice Lake 8375C):** M6i, M6id
- **4th generation Intel Xeon Scalable processors (Sapphire Rapids 8488C):** M7i, M7i-flex

For more information, see [Amazon EC2 Instance Types](#).

Instance performance

EBS-optimized instances enable you to get consistently high performance for your EBS volumes by eliminating contention between Amazon EBS I/O and other network traffic from your instance. Some general purpose instances are EBS-optimized by default at no additional cost. For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).

Flex instance performance

M7i-flex instances offer a balance of compute, memory, and network resources, and they provide the most cost-effective way to run a broad spectrum of general purpose applications. M7i-flex instances provide reliable CPU resources to deliver a baseline CPU performance of 40 percent, which is designed to meet the compute requirements for a majority of general purpose workloads. For times when workloads need more performance, M7i-flex instances provide the ability to exceed baseline CPU and deliver up to 100 percent CPU for 95 percent of the time over a 24-hour window.

M7i-flex instances running at a high CPU utilization that is consistently above the baseline for long periods of time might see a gradual reduction in the maximum burst CPU throughput.

Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see [Enhanced networking on Windows \(p. 1326\)](#).

The following is a summary of network performance for general purpose instances that support enhanced networking.

Note

Instance types indicated with a † have a baseline bandwidth and can use a network I/O credit mechanism to burst beyond their baseline bandwidth on a best effort basis. For more information, see [instance network bandwidth \(p. 1324\)](#).

For 32xlarge and metal instance types that support 200 Gbps, at least 2 ENIs, each attached to a different network card, are required on the instance to achieve 200 Gbps throughput. Each ENI attached to a network card can achieve a max of 170 Gbps.

The following table shows the baseline and burst bandwidth for instance types that use the network I/O credit mechanism to burst beyond their baseline bandwidth.

Instance type	Baseline bandwidth (Gbps)	Burst bandwidth (Gbps)
m5.large	0.75	10.0
m5.xlarge	1.25	10.0
m5.2xlarge	2.5	10.0
m5.4xlarge	5.0	10.0
m5a.large	0.75	10.0
m5a.xlarge	1.25	10.0
m5a.2xlarge	2.5	10.0
m5a.4xlarge	5.0	10.0
m5a.8xlarge	7.5	10.0
m5ad.large	0.75	10.0

Amazon EBS I/O performance

Amazon EBS optimized instances use an optimized configuration stack and provide additional, dedicated capacity for Amazon EBS I/O. This optimization provides the best performance for your Amazon EBS volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).

SSD-based instance store volume I/O performance

If you use all the SSD-based instance store volumes available to your instance, you can get up to the IOPS (4,096 byte block size) performance listed in the following table (at queue depth saturation). Otherwise, you get lower IOPS performance.

Instance Size	100% Random Read IOPS	Write IOPS
m5ad.large	30,000	15,000
m5ad.xlarge	59,000	29,000
m5ad.2xlarge	117,000	57,000
m5ad.4xlarge	234,000	114,000
m5ad.8xlarge	466,666	233,333
m5ad.12xlarge	700,000	340,000
m5ad.16xlarge	933,333	466,666
m5ad.24xlarge	1,400,000	680,000
m5d.large	30,000	15,000
m5d.xlarge	59,000	29,000
m5d.2xlarge	117,000	57,000
m5d.4xlarge	234,000	114,000

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called *over-provisioning*. The SSD-based instance store volumes provided to an instance don't have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see [Instance store volume TRIM support \(p. 2013\)](#).

Release notes

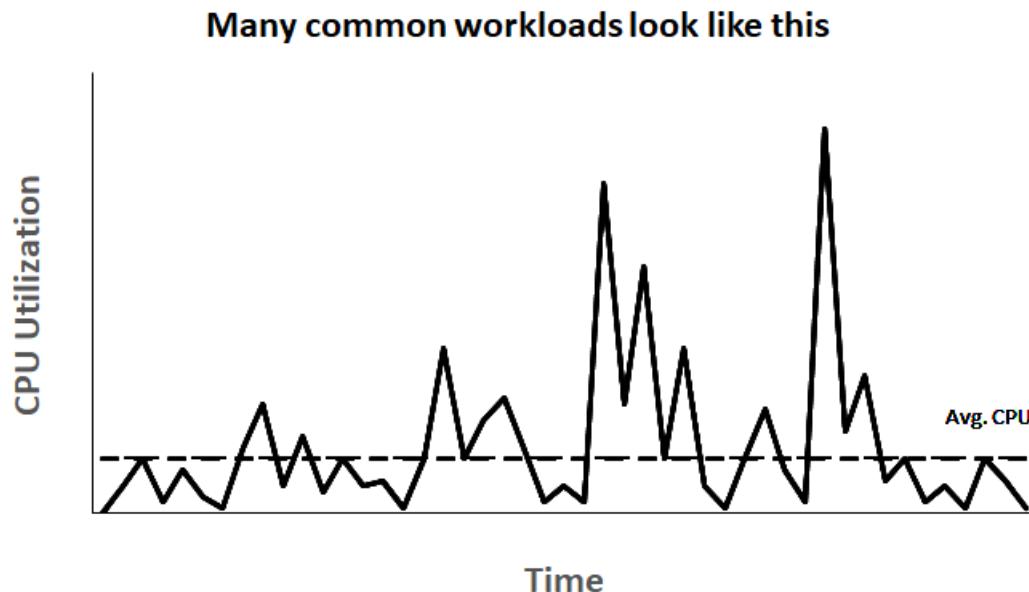

- Instances built on the [Nitro System \(p. 218\)](#), M4, t2.large and larger, t3.large and larger, and t3a.large and larger require 64-bit HVM AMIs. They have high-memory, and require a 64-bit operating system to take advantage of that capacity. HVM AMIs provide superior performance in comparison to paravirtual (PV) AMIs on high-memory instance types. In addition, you must use an HVM AMI to take advantage of enhanced networking.
- Instances built on the [Nitro System \(p. 218\)](#) have the following requirements:
 - [NVMe drivers \(p. 1939\)](#) must be installed
 - [Elastic Network Adapter \(ENA\) drivers \(p. 1327\)](#) must be installed

The current [AWS Windows AMIs \(p. 41\)](#) meet these requirements.

- To get the best performance from your M6i instances, ensure that they have ENA driver version 2.2.3 or later. Using an ENA driver earlier than version 2.0.0 with these instances causes network interface attachment failures. The following AMIs have a compatible ENA driver.
 - AWS Windows AMI from May 2021 or later
- The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. For more information, see [Instance volume limits \(p. 2019\)](#).
- Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.
- To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support.
- Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.
- There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see [How many instances can I run in Amazon EC2?](#) in the Amazon EC2 FAQ.

Burstable performance instances

Many general purpose workloads are on average not busy, and do not require a high level of sustained CPU performance. The following graph illustrates the CPU utilization for many common workloads that customers run in the AWS Cloud today.

These low-to-moderate CPU utilization workloads lead to wastage of CPU cycles and, as a result, you pay for more than you use. To overcome this, you can leverage the low-cost burstable general purpose instances, which are the T instances.

The T instance family provides a baseline CPU performance with the ability to burst above the baseline at any time for as long as required. The baseline CPU is defined to meet the needs of the majority of general purpose workloads, including large-scale micro-services, web servers, small and medium databases, data logging, code repositories, virtual desktops, development and test environments, and business-critical applications. The T instances offer a balance of compute, memory, and network resources, and provide you with the most cost-effective way to run a broad spectrum of general purpose applications that have a low-to-moderate CPU usage. They can save you up to 15% in costs when compared to M instances, and can lead to even more cost savings with smaller, more economical instance sizes, offering as low as 2 vCPUs and 0.5 GiB of memory. The smaller T instance sizes, such as nano, micro, small, and medium, are well suited for workloads that need a small amount of memory and do not expect high CPU usage.

Note

This topic describes burstable CPU. For information about burstable network performance, see [Amazon EC2 instance network bandwidth \(p. 1324\)](#).

EC2 burstable instance types

The EC2 burstable instances consist of T3a and T3 instance types, and the previous generation T2 instance types.

The T4g instance types are the latest generation of burstable instances. They provide the best price for performance, and provide you with the lowest cost of all the EC2 instance types. The T4g instance types are powered by Arm-based [AWS Graviton2](#) processors with extensive ecosystem support from operating systems vendors, independent software vendors, and popular AWS services and applications.

The following table summarizes the key differences between the burstable instance types.

Type	Description	Processor family
Latest generation		
T4g	Lowest cost EC2 instance type with up to 40% higher price/ performance and 20% lower costs vs T3	AWS Graviton2 processors with Arm Neoverse N1 cores
T3a	Lowest cost x86-based instances with 10% lower costs vs T3 instances	AMD 1st gen EPYC processors
T3	Best peak price/performance for x86 workloads with up to 30% lower price/performance vs previous generation T2 instances	Intel Xeon Scalable (Skylake, Cascade Lake processors)
Previous generation		
T2	Previous generation burstable instances	Intel Xeon processors

For information about instance pricing and additional specifications, see [Amazon EC2 Pricing](#) and [Amazon EC2 Instance Types](#). For information about burstable network performance, see [Amazon EC2 instance network bandwidth \(p. 1324\)](#).

If your account is less than 12 months old, you can use a t2.micro instance for free (or a t3.micro instance in Regions where t2.micro is unavailable) within certain usage limits. For more information, see [AWS Free Tier](#).

Supported purchasing options for T instances

- On-Demand Instances
- Reserved Instances
- Dedicated Instances (T3 only)
- Dedicated Hosts (T3 only, in standard mode only)
- Spot Instances

For more information, see [Instance purchasing options \(p. 349\)](#).

Contents

- [Best practices \(p. 246\)](#)
- [Key concepts and definitions for burstable performance instances \(p. 247\)](#)
- [Unlimited mode for burstable performance instances \(p. 253\)](#)
- [Standard mode for burstable performance instances \(p. 260\)](#)
- [Work with burstable performance instances \(p. 270\)](#)
- [Monitor your CPU credits for burstable performance instances \(p. 275\)](#)

Best practices

Follow these best practices to get the maximum benefit from burstable performance instances.

- Ensure that the instance size you choose passes the minimum memory requirements of your operating system and applications. Operating systems with graphical user interfaces that consume significant memory and CPU resources (for example, Windows) might require a `t3.micro` or larger instance size for many use cases. As the memory and CPU requirements of your workload grow over time, you have the flexibility with the T instances to scale to larger instance sizes of the same instance type, or to select another instance type.
- Enable [AWS Compute Optimizer](#) for your account and review the Compute Optimizer recommendations for your workload. Compute Optimizer can help assess whether instances should be upsized to improve performance or downsized for cost savings. Compute Optimizer may also recommend a different instance type based on your scenario. For more information, see [Viewing EC2 instance recommendations](#) in the *AWS Compute Optimizer User Guide*.
- For additional requirements, see [Release notes \(p. 244\)](#).

Key concepts and definitions for burstable performance instances

Traditional Amazon EC2 instance types provide fixed CPU resources, while burstable performance instances provide a baseline level of CPU utilization with the ability to burst CPU utilization above the baseline level. This ensures that you pay only for baseline CPU plus any additional burst CPU usage resulting in lower compute costs. The baseline utilization and ability to burst are governed by CPU credits. Burstable performance instances are the only instance types that use credits for CPU usage.

Each burstable performance instance continuously earns credits when it stays below the CPU baseline, and continuously spends credits when it bursts above the baseline. The amount of credits earned or spent depends on the CPU utilization of the instance:

- If the CPU utilization is below baseline, then credits earned are greater than credits spent.
- If the CPU utilization is equal to baseline, then credits earned are equal to credits spent.
- If the CPU utilization is higher than baseline, then credits spent are higher than credits earned.

When the credits earned are greater than credits spent, then the difference is called accrued credits, which can be used later to burst above baseline CPU utilization. Similarly, when the credits spent are more than credits earned, then the instance behavior depends on the credit configuration mode—Standard mode or Unlimited mode.

In Standard mode, when credits spent are more than credits earned, the instance uses the accrued credits to burst above baseline CPU utilization. If there are no accrued credits remaining, then the instance gradually comes down to baseline CPU utilization and cannot burst above baseline until it accrues more credits.

In Unlimited mode, if the instance bursts above baseline CPU utilization, then the instance first uses the accrued credits to burst. If there are no accrued credits remaining, then the instance spends surplus credits to burst. When its CPU utilization falls below the baseline, it uses the CPU credits that it earns to pay down the surplus credits that it spent earlier. The ability to earn CPU credits to pay down surplus credits enables Amazon EC2 to average the CPU utilization of an instance over a 24-hour period. If the average CPU usage over a 24-hour period exceeds the baseline, the instance is billed for the additional usage at a [flat additional rate](#) per vCPU-hour.

- [Accrued CPU credits life span \(p. 252\)](#)

- [Baseline utilization \(p. 252\)](#)

Key concepts and definitions

The following key concepts and definitions are applicable to burstable performance instances.

CPU utilization

CPU utilization is the percentage of allocated EC2 compute units that are currently in use on the instance. This metric measures the percentage of allocated CPU cycles that are being utilized on an instance. The CPU Utilization CloudWatch metric shows CPU usage per instance and not CPU usage per core. The baseline CPU specification of an instance is also based on the CPU usage per instance. To measure CPU utilization using the AWS Management Console or the AWS CLI, see [Get statistics for a specific instance \(p. 1198\)](#).

CPU credit

A unit of vCPU-time.

Examples:

1 CPU credit = 1 vCPU * 100% utilization * 1 minute.

1 CPU credit = 1 vCPU * 50% utilization * 2 minutes

1 CPU credit = 2 vCPU * 25% utilization * 2 minutes

Baseline utilization

The baseline utilization is the level at which the CPU can be utilized for a net credit balance of zero, when the number of CPU credits being earned matches the number of CPU credits being used.

Baseline utilization is also known as the baseline. Baseline utilization is expressed as a percentage of vCPU utilization, which is calculated as follows: Baseline utilization % = (number of credits earned/number of vCPUs)/60 minutes.

For the baseline utilization of each burstable performance instance type, see the [credit table \(p. 250\)](#).

Earned credits

Credits earned continuously by an instance when it is running.

Number of credits earned per hour = % baseline utilization * number of vCPUs * 60 minutes

Example:

A t3.nano with 2 vCPUs and a baseline utilization of 5% earns 6 credits per hour, calculated as follows:

2 vCPUs * 5% baseline * 60 minutes = 6 credits per hour

Spent or used credits

Credits used continuously by an instance when it is running.

CPU credits spent per minute = Number of vCPUs * CPU utilization * 1 minute

Accrued credits

Unspent CPU credits when an instance uses fewer credits than is required for baseline utilization. In other words, accrued credits = (Earned credits – Used credits) below baseline.

Example:

If a t3.nano is running at 2% CPU utilization, which is below its baseline of 5% for an hour, the accrued credits is calculated as follows:

Accrued CPU credits = (Earned credits per hour – Used credits per hour) = 6 – 2 vCPUs * 2% CPU utilization * 60 minutes = 6 – 2.4 = 3.6 accrued credits per hour

Credit accrual limit

Depends on the instance size but in general is equal to the number of maximum credits earned in 24 hours.

Example:

For t3.nano, the credit accrual limit = 24 * 6 = 144 credits

Launch credits

Only applicable for T2 instances configured for Standard mode. Launch credits are a limited number of CPU credits that are allocated to a new T2 instance so that, when launched in Standard mode, it can burst above the baseline.

Surplus credits

Credits that are spent by an instance after it depletes its accrued credit balance. The surplus credits are designed for burstable instances to sustain high performance for an extended period of time, and are only used in Unlimited mode. The surplus credits balance is used to determine how many credits were used by the instance for bursting in Unlimited mode.

Standard mode

Credit configuration mode, which allows an instance to burst above the baseline by spending credits it has accrued in its credit balance.

Unlimited mode

Credit configuration mode, which allows an instance to burst above the baseline by sustaining high CPU utilization for any period of time whenever required. The hourly instance price automatically covers all CPU usage spikes if the average CPU utilization of the instance is at or below the baseline over a rolling 24-hour period or the instance lifetime, whichever is shorter. If the instance runs at higher CPU utilization for a prolonged period, it can do so for a [flat additional rate](#) per vCPU-hour.

The following table summarizes the key credit differences between the burstable instance types.

Type	Type of CPU credits supported	Credit configuration modes	Accrued CPU credits lifespan between instance starts and stops
Latest generation			
T4g	Earned credits, Accrued credits, Spent credits, Surplus credits (Unlimited mode only)	Standard, Unlimited (default)	7 days (credits persist for 7 days after an instance stops)
T3a	Earned credits, Accrued credits, Spent credits, Surplus credits (Unlimited mode only)	Standard, Unlimited (default)	7 days (credits persist for 7 days after an instance stops)

Type	Type of CPU credits supported	Credit configuration modes	Accrued CPU credits lifespan between instance starts and stops
T3	Earned credits, Accrued credits, Spent credits, Surplus credits (Unlimited mode only)	Standard, Unlimited (default)	7 days (credits persist for 7 days after an instance stops)
Previous generation			
T2	Earned credits, Accrued credits, Spent credits, Launch credits (Standard mode only), Surplus credits (Unlimited mode only)	Standard (default), Unlimited	0 days (credits are lost when an instance stops)

Note

Unlimited mode is not supported for T3 instances that are launched on a Dedicated Host.

Earn CPU credits

Each burstable performance instance continuously earns (at a millisecond-level resolution) a set rate of CPU credits per hour, depending on the instance size. The accounting process for whether credits are accrued or spent also happens at a millisecond-level resolution, so you don't have to worry about overspending CPU credits; a short burst of CPU uses a small fraction of a CPU credit.

If a burstable performance instance uses fewer CPU resources than is required for baseline utilization (such as when it is idle), the unspent CPU credits are accrued in the CPU credit balance. If a burstable performance instance needs to burst above the baseline utilization level, it spends the accrued credits. The more credits that a burstable performance instance has accrued, the more time it can burst beyond its baseline when more CPU utilization is needed.

The following table lists the burstable performance instance types, the rate at which CPU credits are earned per hour, the maximum number of earned CPU credits that an instance can accrue, the number of vCPUs per instance, and the baseline utilization as a percentage of a full core (using a single vCPU).

Instance type	CPU credits earned per hour	Maximum earned credits that can be accrued*	vCPUs***	Baseline utilization per vCPU
T2				
t2.nano	3	72	1	5%
t2.micro	6	144	1	10%
t2.small	12	288	1	20%
t2.medium	24	576	2	20%**
t2.large	36	864	2	30%**
t2.xlarge	54	1296	4	22.5%**
t2.2xlarge	81.6	1958.4	8	17%**

Instance type	CPU credits earned per hour	Maximum earned credits that can be accrued*	vCPUs***	Baseline utilization per vCPU
T3				
t3.nano	6	144	2	5%**
t3.micro	12	288	2	10%**
t3.small	24	576	2	20%**
t3.medium	24	576	2	20%**
t3.large	36	864	2	30%**
t3.xlarge	96	2304	4	40%**
t3.2xlarge	192	4608	8	40%**
T3a				
t3a.nano	6	144	2	5%**
t3a.micro	12	288	2	10%**
t3a.small	24	576	2	20%**
t3a.medium	24	576	2	20%**
t3a.large	36	864	2	30%**
t3a.xlarge	96	2304	4	40%**
t3a.2xlarge	192	4608	8	40%**

* The number of credits that can be accrued is equivalent to the number of credits that can be earned in a 24-hour period.

** The percentage baseline utilization in the table is per vCPU. In CloudWatch, CPU utilization is shown per vCPU. For example, the CPU utilization for a t3.large instance operating at the baseline level is shown as 30% in CloudWatch CPU metrics. For information about how to calculate the baseline utilization, see [Baseline utilization \(p. 252\)](#).

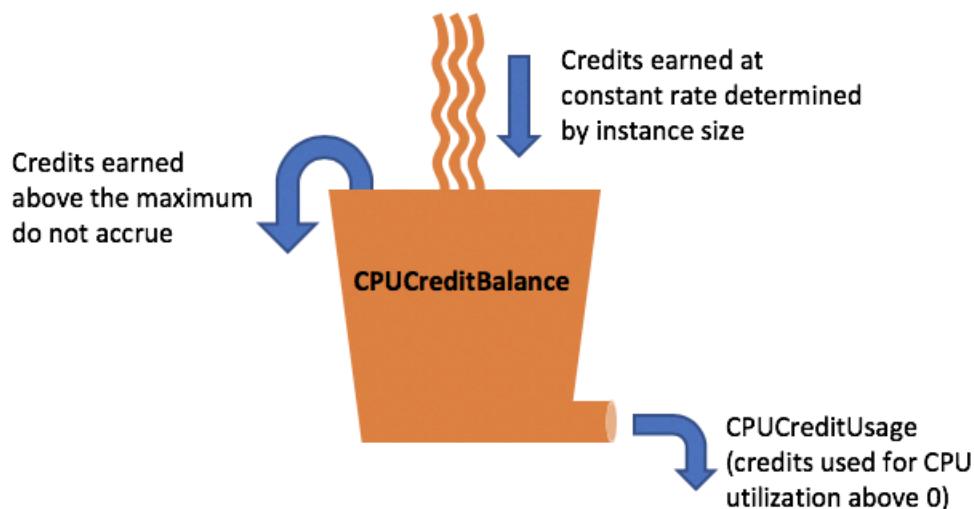

*** Each vCPU is a thread of either an Intel Xeon core or an AMD EPYC core, except for T2 instances.

CPU credit earn rate

The number of CPU credits earned per hour is determined by the instance size. For example, a t3.nano earns six credits per hour, while a t3.small earns 24 credits per hour. The preceding table lists the credit earn rate for all instances.

CPU credit accrual limit

While earned credits never expire on a running instance, there is a limit to the number of earned credits that an instance can accrue. The limit is determined by the CPU credit balance limit. After the limit is reached, any new credits that are earned are discarded, as indicated by the following image. The full bucket indicates the CPU credit balance limit, and the spillover indicates the newly earned credits that exceed the limit.

The CPU credit balance limit differs for each instance size. For example, a t3.micro instance can accrue a maximum of 288 earned CPU credits in the CPU credit balance. The preceding table lists the maximum number of earned credits that each instance can accrue.

T2 Standard instances also earn launch credits. Launch credits do not count towards the CPU credit balance limit. If a T2 instance has not spent its launch credits, and remains idle over a 24-hour period while accruing earned credits, its CPU credit balance appears as over the limit. For more information, see [Launch credits \(p. 261\)](#).

T3a and T3 instances do not earn launch credits. These instances launch as unlimited by default, and therefore can burst immediately upon start without any launch credits. T3 instances launched on a Dedicated Host launch as standard by default; unlimited mode is not supported for T3 instances on a Dedicated Host.

Accrued CPU credits life span

CPU credits on a running instance do not expire.

For T2, the CPU credit balance does not persist between instance stops and starts. If you stop a T2 instance, the instance loses all its accrued credits.

For T3a and T3, the CPU credit balance persists for seven days after an instance stops and the credits are lost thereafter. If you start the instance within seven days, no credits are lost.

For more information, see CPUCreditBalance in the [CloudWatch metrics table \(p. 276\)](#).

Baseline utilization

The *baseline utilization* is the level at which the CPU can be utilized for a net credit balance of zero, when the number of CPU credits being earned matches the number of CPU credits being used. Baseline utilization is also known as *the baseline*.

Baseline utilization is expressed as a percentage of vCPU utilization, which is calculated as follows:

$$(\text{number of credits earned}/\text{number of vCPUs})/60 \text{ minutes} = \% \text{ baseline utilization}$$

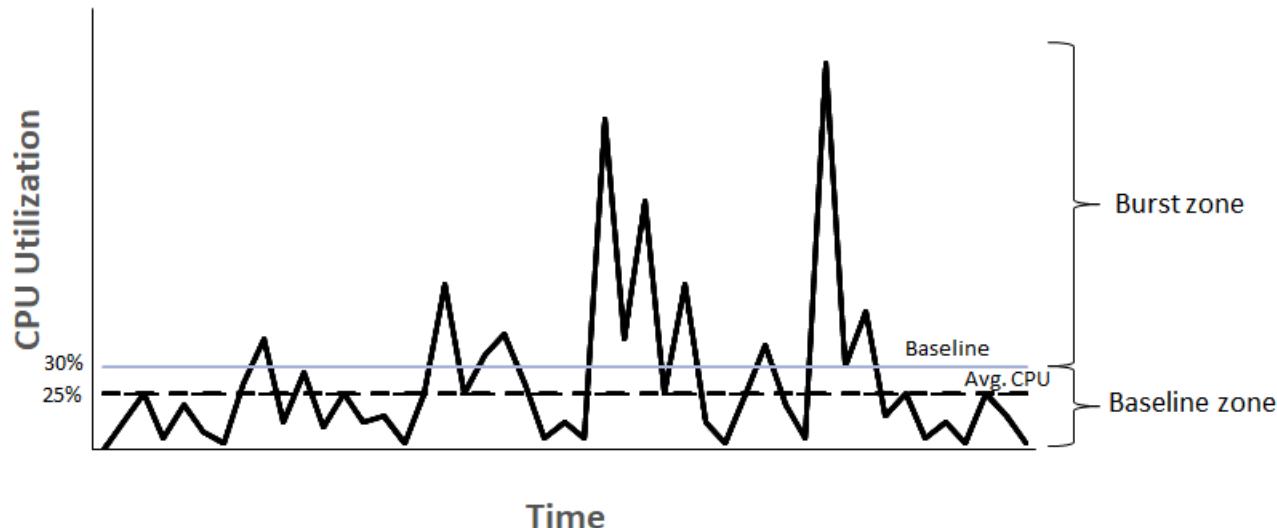

For example, a t3.nano instance, with 2 vCPUs, earns 6 credits per hour, resulting in a baseline utilization of 5%, which is calculated as follows:

$$(6 \text{ credits earned}/2 \text{ vCPUs})/60 \text{ minutes} = 5\% \text{ baseline utilization}$$

A t3.xlarge instance, with 4 vCPUs, earns 96 credits per hour, resulting in a baseline utilization of 40% ((96/4)/60).

The following graph provides an example of a t3.large with an average CPU utilization below the baseline.

Example of t3.large

Unlimited mode for burstable performance instances

A burstable performance instance configured as unlimited can sustain high CPU utilization for any period of time whenever required. The hourly instance price automatically covers all CPU usage spikes if the average CPU utilization of the instance is at or below the baseline over a rolling 24-hour period or the instance lifetime, whichever is shorter.

For the vast majority of general-purpose workloads, instances configured as unlimited provide ample performance without any additional charges. If the instance runs at higher CPU utilization for a prolonged period, it can do so for a flat additional rate per vCPU-hour. For information about pricing, see [Amazon EC2 pricing](#) and [T2/T3/T4 Unlimited Mode Pricing](#).

If you use a t2.micro or t3.micro instance under the [AWS Free Tier](#) offer and use it in unlimited mode, charges might apply if your average utilization over a rolling 24-hour period exceeds the [baseline utilization \(p. 252\)](#) of the instance.

T3a and T3 instances launch as unlimited by default (unless you [change the default \(p. 274\)](#)). If the average CPU usage over a 24-hour period exceeds the baseline, you incur charges for surplus credits. If you launch Spot Instances as unlimited and plan to use them immediately and for a short duration, with no idle time for accruing CPU credits, you incur charges for surplus credits. We recommend that you launch your Spot Instances in [standard \(p. 260\)](#) mode to avoid paying higher costs. For more information, see [Surplus credits can incur charges \(p. 256\)](#) and [Burstable performance instances \(p. 457\)](#).

Note

T3 instances launched on a Dedicated Host launch as standard by default; unlimited mode is not supported for T3 instances on a Dedicated Host.

Contents

- [What happens to credits when switching between Unlimited and Standard \(p. 257\)](#)
- [Monitor credit usage \(p. 257\)](#)
- [Unlimited mode examples \(p. 258\)](#)
 - [Example 1: Explain credit use with T3 Unlimited \(p. 258\)](#)
 - [Example 2: Explain credit use with T2 Unlimited \(p. 259\)](#)

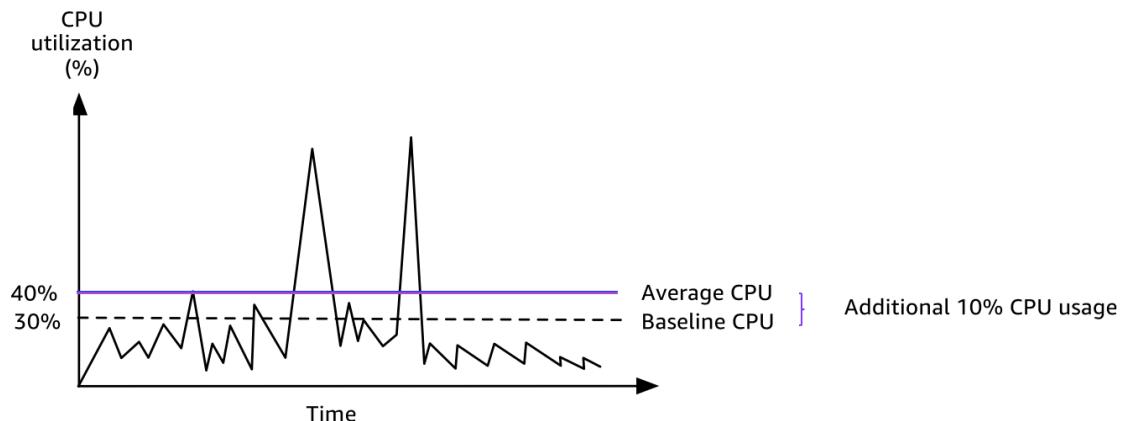

Unlimited mode concepts

The unlimited mode is a credit configuration option for burstable performance instances. It can be enabled or disabled at any time for a running or stopped instance. You can [set unlimited as the default credit option \(p. 274\)](#) at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option.

How Unlimited burstable performance instances work

If a burstable performance instance configured as unlimited depletes its CPU credit balance, it can spend *surplus* credits to burst beyond the [baseline \(p. 252\)](#). When its CPU utilization falls below the baseline, it uses the CPU credits that it earns to pay down the surplus credits that it spent earlier. The ability to earn CPU credits to pay down surplus credits enables Amazon EC2 to average the CPU utilization of an instance over a 24-hour period. If the average CPU usage over a 24-hour period exceeds the baseline, the instance is billed for the additional usage at a [flat additional rate](#) per vCPU-hour.

The following graph shows the CPU usage of a t3.large. The baseline CPU utilization for a t3.large is 30%. If the instance runs at 30% CPU utilization or less on average over a 24-hour period, there is no additional charge because the cost is already covered by the instance hourly price. However, if the instance runs at 40% CPU utilization on average over a 24-hour period, as shown in the graph, the instance is billed for the additional 10% CPU usage at a [flat additional rate](#) per vCPU-hour.

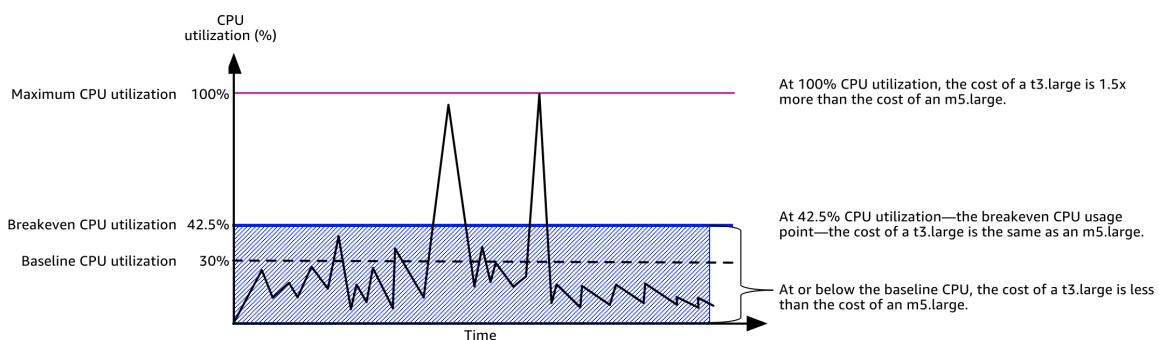

For more information about the baseline utilization per vCPU for each instance type and how many credits each instance type earns, see the [credit table \(p. 250\)](#).

When to use unlimited mode versus fixed CPU

When determining whether you should use a burstable performance instance in unlimited mode, such as T3, or a fixed performance instance, such as M5, you need to determine the breakeven CPU usage. The breakeven CPU usage for a burstable performance instance is the point at which a burstable performance instance costs the same as a fixed performance instance. The breakeven CPU usage helps you determine the following:

- If the average CPU usage over a 24-hour period is at or below the breakeven CPU usage, use a burstable performance instance in unlimited mode so that you can benefit from the lower price of a burstable performance instance while getting the same performance as a fixed performance instance.
- If the average CPU usage over a 24-hour period is above the breakeven CPU usage, the burstable performance instance will cost more than the equivalently-sized fixed performance instance. If a T3 instance continuously bursts at 100% CPU, you end up paying approximately 1.5 times the price of an equivalently-sized M5 instance.

The following graph shows the breakeven CPU usage point where a t3.large costs the same as an m5.large. The breakeven CPU usage point for a t3.large is 42.5%. If the average CPU usage is at 42.5%, the cost of running the t3.large is the same as an m5.large, and is more expensive if the average CPU usage is above 42.5%. If the workload needs less than 42.5% average CPU usage, you can benefit from the lower price of the t3.large while getting the same performance as an m5.large.

The following table shows how to calculate the breakeven CPU usage threshold so that you can determine when it's less expensive to use a burstable performance instance in unlimited mode or a fixed performance instance. The columns in the table are labeled A through K.

Instance type	vCPUs	T3 price*/ hour	M5 price*/ hour	Price difference	T3 baseline utilization per vCPU (%)	Charge per hour for surplus credits	Charge per vCPU minute available	Additiona burst minutes available per vCPU	Additiona CPU % available per vCPU	Breakeven CPU %
A	B	C	D	E = D - C	F	G	H = G / 60	I = E / H	J = (I / 60) / B	K = F + J
t3.large	2	\$0.0835	\$0.096	\$0.0125	30%	\$0.05	\$0.000833	15	12.5%	42.5%

* Price is based on us-east-1 and Linux OS.

The table provides the following information:

- Column A shows the instance type, t3.large.
- Column B shows the number of vCPUs for the t3.large.
- Column C shows the price of a t3.large per hour.
- Column D shows the price of an m5.large per hour.
- Column E shows the price difference between the t3.large and the m5.large.
- Column F shows the baseline utilization per vCPU of the t3.large, which is 30%. At the baseline, the hourly cost of the instance covers the cost of the CPU usage.
- Column G shows the [flat additional rate](#) per vCPU-hour that an instance is charged if it bursts at 100% CPU after it has depleted its earned credits.
- Column H shows the [flat additional rate](#) per vCPU-minute that an instance is charged if it bursts at 100% CPU after it has depleted its earned credits.
- Column I shows the number of additional minutes that the t3.large can burst per hour at 100% CPU while paying the same price per hour as an m5.large.
- Column J shows the additional CPU usage (in %) over baseline that the instance can burst while paying the same price per hour as an m5.large.
- Column K shows the breakeven CPU usage (in %) that the t3.large can burst without paying more than the m5.large. Anything above this, and the t3.large costs more than the m5.large.

The following table shows the breakeven CPU usage (in %) for T3 instance types compared to the similarly-sized M5 instance types.

T3 instance type	Breakeven CPU usage (in %) for T3 compared to M5
t3.large	42.5%
t3.xlarge	52.5%
t3.2xlarge	52.5%

Surplus credits can incur charges

If the average CPU utilization of an instance is at or below the baseline, the instance incurs no additional charges. Because an instance earns a [maximum number of credits \(p. 250\)](#) in a 24-hour period (for example, a t3.micro instance can earn a maximum of 288 credits in a 24-hour period), it can spend surplus credits up to that maximum without being charged.

However, if CPU utilization stays above the baseline, the instance cannot earn enough credits to pay down the surplus credits that it has spent. The surplus credits that are not paid down are charged at a flat additional rate per vCPU-hour. For information about the rate, see [T2/T3/T4g Unlimited Mode Pricing](#).

Surplus credits that were spent earlier are charged when any of the following occurs:

- The spent surplus credits exceed the [maximum number of credits \(p. 250\)](#) the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour.
- The instance is stopped or terminated.
- The instance is switched from unlimited to standard.

Spent surplus credits are tracked by the CloudWatch metric `CPUSurplusCreditBalance`. Surplus credits that are charged are tracked by the CloudWatch metric `CPUSurplusCreditsCharged`. For more information, see [Additional CloudWatch metrics for burstable performance instances \(p. 275\)](#).

No launch credits for T2 Unlimited instances

T2 Standard instances receive [launch credits \(p. 261\)](#), but T2 Unlimited instances do not. A T2 Unlimited instance can burst beyond the baseline at any time with no additional charge, as long as its average CPU utilization is at or below the baseline over a rolling 24-hour window or its lifetime, whichever is shorter. As such, T2 Unlimited instances do not require launch credits to achieve high performance immediately after launch.

If a T2 instance is switched from standard to unlimited, any accrued launch credits are removed from the `CPUCreditBalance` before the remaining `CPUCreditBalance` is carried over.

T3a and T3 instances never receive launch credits because they support Unlimited mode. The Unlimited mode credit configuration enables T4g, T3a and T3 instances to use as much CPU as needed to burst beyond baseline and for as long as needed.

Enable unlimited mode

You can switch from unlimited to standard, and from standard to unlimited, at any time on a running or stopped instance. For more information, see [Launch a burstable performance instance as Unlimited or Standard \(p. 270\)](#) and [Modify the credit specification of a burstable performance instance \(p. 273\)](#).

You can set unlimited as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option. For more information, see [Set the default credit specification for the account \(p. 274\)](#).

You can check whether your burstable performance instance is configured as unlimited or standard using the Amazon EC2 console or the AWS CLI. For more information, see [View the credit specification of a burstable performance instance \(p. 273\)](#) and [View the default credit specification \(p. 275\)](#).

What happens to credits when switching between Unlimited and Standard

`CPUCreditBalance` is a CloudWatch metric that tracks the number of credits accrued by an instance. `CPUSurplusCreditBalance` is a CloudWatch metric that tracks the number of surplus credits spent by an instance.

When you change an instance configured as unlimited to standard, the following occurs:

- The `CPUCreditBalance` value remains unchanged and is carried over.
- The `CPUSurplusCreditBalance` value is immediately charged.

When a standard instance is switched to unlimited, the following occurs:

- The `CPUCreditBalance` value containing accrued earned credits is carried over.
- For T2 Standard instances, any launch credits are removed from the `CPUCreditBalance` value, and the remaining `CPUCreditBalance` value containing accrued earned credits is carried over.

Monitor credit usage

To see if your instance is spending more credits than the baseline provides, you can use CloudWatch metrics to track usage, and you can set up hourly alarms to be notified of credit usage. For more information, see [Monitor your CPU credits for burstable performance instances \(p. 275\)](#).

Unlimited mode examples

The following examples explain credit use for instances that are configured as unlimited.

Examples

- [Example 1: Explain credit use with T3 Unlimited \(p. 258\)](#)
- [Example 2: Explain credit use with T2 Unlimited \(p. 259\)](#)

Example 1: Explain credit use with T3 Unlimited

In this example, you see the CPU utilization of a t3.nano instance launched as unlimited, and how it spends *earned* and *surplus* credits to sustain CPU utilization.

A t3.nano instance earns 144 CPU credits over a rolling 24-hour period, which it can redeem for 144 minutes of vCPU use. When it depletes its CPU credit balance (represented by the CloudWatch metric CPUCreditBalance), it can spend *surplus* CPU credits—that it has *not yet earned*—to burst for as long as it needs. Because a t3.nano instance earns a maximum of 144 credits in a 24-hour period, it can spend surplus credits up to that maximum without being charged immediately. If it spends more than 144 CPU credits, it is charged for the difference at the end of the hour.

The intent of the example, illustrated by the following graph, is to show how an instance can burst using surplus credits even after it depletes its CPUCreditBalance. The following workflow references the numbered points on the graph:

P1 – At 0 hours on the graph, the instance is launched as unlimited and immediately begins to earn credits. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. For the first 24 hours, CPUCreditUsage is at 0, and the CPUCreditBalance value reaches its maximum of 144.

P2 – For the next 12 hours, CPU utilization is at 2.5%, which is below the 5% baseline. The instance earns more credits than it spends, but the CPUCreditBalance value cannot exceed its maximum of 144 credits.

P3 – For the next 24 hours, CPU utilization is at 7% (above the baseline), which requires a spend of 57.6 credits. The instance spends more credits than it earns, and the CPUCreditBalance value reduces to 86.4 credits.

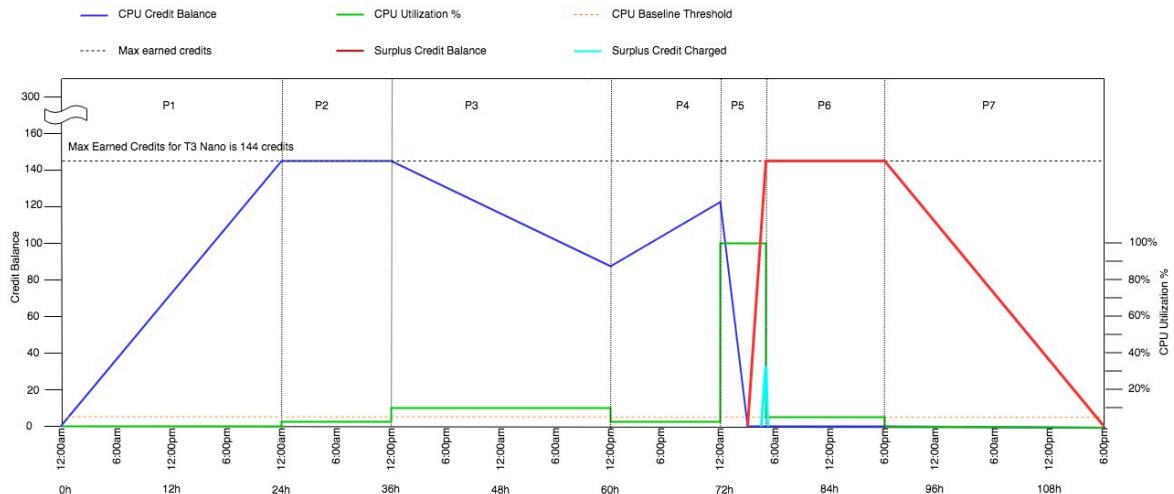

P4 – For the next 12 hours, CPU utilization decreases to 2.5% (below the baseline), which requires a spend of 36 credits. In the same time, the instance earns 72 credits. The instance earns more credits than it spends, and the CPUCreditBalance value increases to 122 credits.

P5 – For the next 5 hours, the instance bursts at 100% CPU utilization, and spends a total of 570 credits to sustain the burst. About an hour into this period, the instance depletes its entire CPUCreditBalance of 122 credits, and starts to spend surplus credits to sustain the high CPU utilization, totaling 448 surplus credits in this period ($570 - 122 = 448$). When the CPUSurplusCreditBalance value reaches 144 CPU credits (the maximum a t3.nano instance can earn in a 24-hour period), any surplus credits spent thereafter cannot be offset by earned credits. The surplus credits spent thereafter amounts to 304 credits ($448 - 144 = 304$), which results in a small additional charge at the end of the hour for 304 credits.

P6 – For the next 13 hours, CPU utilization is at 5% (the baseline). The instance earns as many credits as it spends, with no excess to pay down the CPUSurplusCreditBalance. The CPUSurplusCreditBalance value remains at 144 credits.

P7 – For the last 24 hours in this example, the instance is idle and CPU utilization is 0%. During this time, the instance earns 144 credits, which it uses to pay down the CPUSurplusCreditBalance.

Amazon Elastic Compute Cloud
User Guide for Windows Instances
General purpose

Example 2: Explain credit use with T2 Unlimited

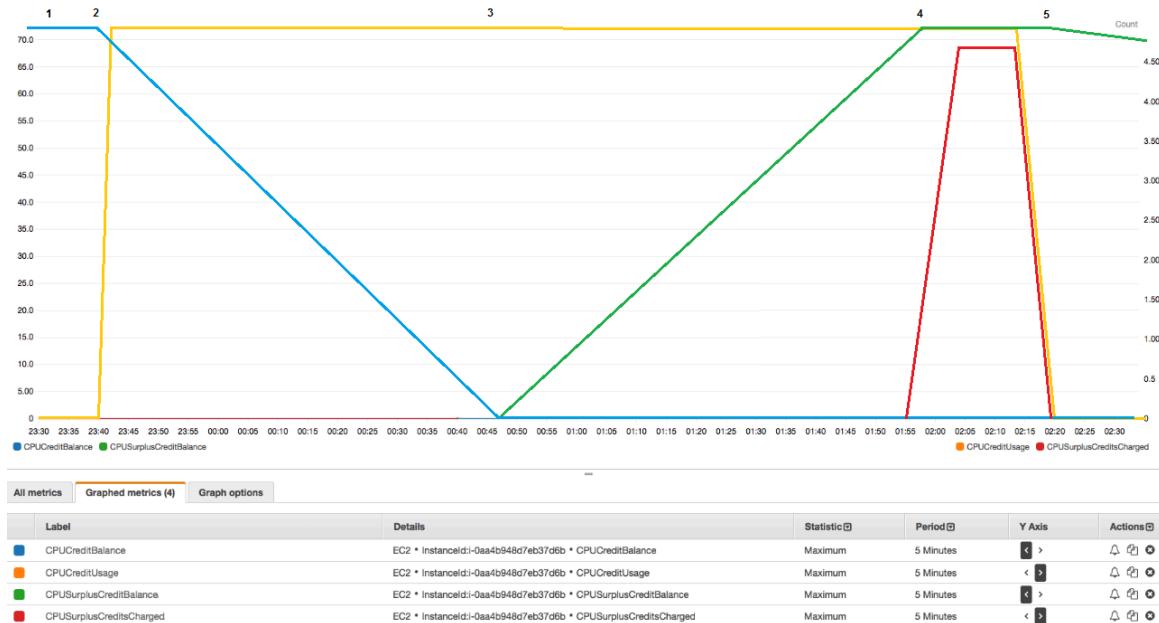

In this example, you see the CPU utilization of a t2.nano instance launched as unlimited, and how it spends *earned* and *surplus* credits to sustain CPU utilization.

A t2.nano instance earns 72 CPU credits over a rolling 24-hour period, which it can redeem for 72 minutes of vCPU use. When it depletes its CPU credit balance (represented by the CloudWatch metric CPUCreditBalance), it can spend *surplus* CPU credits—that it has *not yet earned*—to burst for as long as it needs. Because a t2.nano instance earns a maximum of 72 credits in a 24-hour period, it can spend surplus credits up to that maximum without being charged immediately. If it spends more than 72 CPU credits, it is charged for the difference at the end of the hour.

The intent of the example, illustrated by the following graph, is to show how an instance can burst using surplus credits even after it depletes its CPUCreditBalance. You can assume that, at the start of the time line in the graph, the instance has an accrued credit balance equal to the maximum number of credits it can earn in 24 hours. The following workflow references the numbered points on the graph:

- 1 – In the first 10 minutes, CPUCreditUsage is at 0, and the CPUCreditBalance value remains at its maximum of 72.
- 2 – At 23:40, as CPU utilization increases, the instance spends CPU credits and the CPUCreditBalance value decreases.
- 3 – At around 00:47, the instance depletes its entire CPUCreditBalance, and starts to spend surplus credits to sustain high CPU utilization.
- 4 – Surplus credits are spent until 01:55, when the CPUSurplusCreditBalance value reaches 72 CPU credits. This is equal to the maximum a t2.nano instance can earn in a 24-hour period. Any surplus credits spent thereafter cannot be offset by earned credits within the 24-hour period, which results in a small additional charge at the end of the hour.
- 5 – The instance continues to spend surplus credits until around 02:20. At this time, CPU utilization falls below the baseline, and the instance starts to earn credits at 3 credits per hour (or 0.25 credits every 5 minutes), which it uses to pay down the CPUSurplusCreditBalance. After the CPUSurplusCreditBalance value reduces to 0, the instance starts to accrue earned credits in its CPUCreditBalance at 0.25 credits every 5 minutes.

Amazon Elastic Compute Cloud
User Guide for Windows Instances
General purpose

Calculating the bill

Surplus credits cost \$0.096 per vCPU-hour. The instance spent approximately 25 surplus credits between 01:55 and 02:20, which is equivalent to 0.42 vCPU-hours.

Additional charges for this instance are $0.42 \text{ vCPU-hours} \times \$0.096/\text{vCPU-hour} = \0.04032 , rounded to \$0.04.

Here is the month-end bill for this T2 Unlimited instance:

Amazon Elastic Compute Cloud running Windows

\$0.0081 per On Demand Windows t2.nano Instance Hour	720.000 Hrs	\$5.83
------------------------------------------------------	-------------	--------

Amazon Elastic Compute Cloud T2 CPU Credits

\$0.096 per vCPU-Hour of T2 CPU credits	0.420 vCPU-Hours	\$0.04
-----------------------------------------	------------------	--------

You can set billing alerts to be notified every hour of any accruing charges, and take action if required.

Standard mode for burstable performance instances

A burstable performance instance configured as standard is suited to workloads with an average CPU utilization that is consistently below the baseline CPU utilization of the instance. To burst above the baseline, the instance spends credits that it has accrued in its CPU credit balance. If the instance is running low on accrued credits, CPU utilization is gradually lowered to the baseline level, so that the instance does not experience a sharp performance drop-off when its accrued CPU credit balance is depleted. For more information, see [Key concepts and definitions for burstable performance instances \(p. 247\)](#).

Contents

 - [Period 6: 76 – 90 hours \(p. 268\)](#)
 - [Period 7: 91 – 96 hours \(p. 269\)](#)

Standard mode concepts

The standard mode is a configuration option for burstable performance instances. It can be enabled or disabled at any time for a running or stopped instance. You can [set standard as the default credit option \(p. 274\)](#) at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option.

How standard burstable performance instances work

When a burstable performance instance configured as standard is in a running state, it continuously earns (at a millisecond-level resolution) a set rate of earned credits per hour. For T2 Standard, when the instance is stopped, it loses all its accrued credits, and its credit balance is reset to zero. When it is restarted, it receives a new set of launch credits, and begins to accrue earned credits. For T3a and T3 Standard instances, the CPU credit balance persists for seven days after the instance stops and the credits are lost thereafter. If you start the instance within seven days, no credits are lost.

T2 Standard instances receive two types of [CPU credits \(p. 248\)](#): *earned credits* and *launch credits*. When a T2 Standard instance is in a running state, it continuously earns (at a millisecond-level resolution) a set rate of earned credits per hour. At start, it has not yet earned credits for a good startup experience; therefore, to provide a good startup experience, it receives launch credits at start, which it spends first while it accrues earned credits.

T3a and T3 instances do not receive launch credits because they support Unlimited mode. The Unlimited mode credit configuration enables T4g, T3a and T3 instances to use as much CPU as needed to burst beyond baseline and for as long as needed.

Launch credits

T2 Standard instances get 30 launch credits per vCPU at launch or start, and T1 Standard instances get 15 launch credits. For example, a t2.micro instance has one vCPU and gets 30 launch credits, while a t2.xlarge instance has four vCPUs and gets 120 launch credits. Launch credits are designed to provide a good startup experience to allow instances to burst immediately after launch before they have accrued earned credits.

Launch credits are spent first, before earned credits. Unspent launch credits are accrued in the CPU credit balance, but do not count towards the CPU credit balance limit. For example, a t2.micro instance has a CPU credit balance limit of 144 earned credits. If it is launched and remains idle for 24 hours, its CPU credit balance reaches 174 (30 launch credits + 144 earned credits), which is over the limit. However, after the instance spends the 30 launch credits, the credit balance cannot exceed 144. For more information about the CPU credit balance limit for each instance size, see the [credit table \(p. 250\)](#).

The following table lists the initial CPU credit allocation received at launch or start, and the number of vCPUs.

Instance type	Launch credits	vCPUs
t1.micro	15	1
t2.nano	30	1
t2.micro	30	1
t2.small	30	1
t2.medium	60	2
t2.large	60	2
t2.xlarge	120	4
t2.2xlarge	240	8

Launch credit limits

There is a limit to the number of times T2 Standard instances can receive launch credits. The default limit is 100 launches or starts of all T2 Standard instances combined per account, per Region, per rolling 24-hour period. For example, the limit is reached when one instance is stopped and started 100 times within a 24-hour period, or when 100 instances are launched within a 24-hour period, or other combinations that equate to 100 starts. New accounts may have a lower limit, which increases over time based on your usage.

Tip

To ensure that your workloads always get the performance they need, switch to [Unlimited mode for burstable performance instances \(p. 253\)](#) or consider using a larger instance size.

Differences between launch credits and earned credits

The following table lists the differences between launch credits and earned credits.

	Launch credits	Earned credits
Credit earn rate	T2 Standard instances get 30 launch credits per vCPU at launch or start. If a T2 instance is switched from unlimited to standard, it does not get launch credits at the time of switching.	Each T2 instance continuously earns (at a millisecond-level resolution) a set rate of CPU credits per hour, depending on the instance size. For more information about the number of CPU credits earned per instance size, see the credit table (p. 250) .
Credit earn limit	The limit for receiving launch credits is 100 launches or starts of all T2 Standard instances combined per account, per Region, per rolling 24-hour period. New accounts may have a lower limit, which increases over time based on your usage.	A T2 instance cannot accrue more credits than the CPU credit balance limit. If the CPU credit balance has reached its limit, any credits that are earned after the limit is reached are discarded. Launch credits do not count towards the limit. For more information about the CPU credit balance limit for each T2 instance size, see the credit table (p. 250) .
Credit use	Launch credits are spent first, before earned credits.	Earned credits are spent only after all launch credits are spent.

	Launch credits	Earned credits
Credit expiration	When a T2 Standard instance is running, launch credits do not expire. When a T2 Standard instance stops or is switched to T2 Unlimited, all launch credits are lost.	When a T2 instance is running, earned credits that have accrued do not expire. When the T2 instance stops, all accrued earned credits are lost.

The number of accrued launch credits and accrued earned credits is tracked by the CloudWatch metric CPUCreditBalance. For more information, see CPUCreditBalance in the [CloudWatch metrics table \(p. 276\)](#).

Standard mode examples

The following examples explain credit use when instances are configured as standard.

Examples

- [Example 1: Explain credit use with T3 Standard \(p. 263\)](#)
- [Example 2: Explain credit use with T2 Standard \(p. 264\)](#)

Example 1: Explain credit use with T3 Standard

In this example, you see how a t3.nano instance launched as standard earns, accrues, and spends *earned* credits. You see how the credit balance reflects the accrued *earned* credits.

A running t3.nano instance earns 144 credits every 24 hours. Its credit balance limit is 144 earned credits. After the limit is reached, new credits that are earned are discarded. For more information about the number of credits that can be earned and accrued, see the [credit table \(p. 250\)](#).

You might launch a T3 Standard instance and use it immediately. Or, you might launch a T3 Standard instance and leave it idle for a few days before running applications on it. Whether an instance is used or remains idle determines if credits are spent or accrued. If an instance remains idle for 24 hours from the time it is launched, the credit balance reaches its limit, which is the maximum number of earned credits that can be accrued.

This example describes an instance that remains idle for 24 hours from the time it is launched, and walks you through seven periods of time over a 96-hour period, showing the rate at which credits are earned, accrued, spent, and discarded, and the value of the credit balance at the end of each period.

The following workflow references the numbered points on the graph:

P1 – At 0 hours on the graph, the instance is launched as standard and immediately begins to earn credits. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. For the first 24 hours, CPUCreditUsage is at 0, and the CPUCreditBalance value reaches its maximum of 144.

P2 – For the next 12 hours, CPU utilization is at 2.5%, which is below the 5% baseline. The instance earns more credits than it spends, but the CPUCreditBalance value cannot exceed its maximum of 144 credits. Any credits that are earned in excess of the limit are discarded.

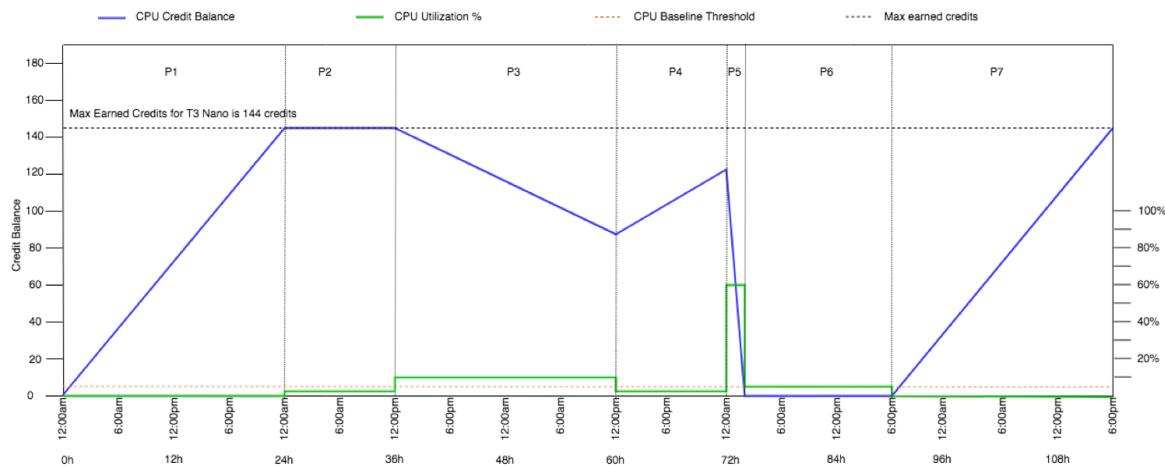

P3 – For the next 24 hours, CPU utilization is at 7% (above the baseline), which requires a spend of 57.6 credits. The instance spends more credits than it earns, and the CPUCreditBalance value reduces to 86.4 credits.

P4 – For the next 12 hours, CPU utilization decreases to 2.5% (below the baseline), which requires a spend of 36 credits. In the same time, the instance earns 72 credits. The instance earns more credits than it spends, and the CPUCreditBalance value increases to 122 credits.

P5 – For the next two hours, the instance bursts at 60% CPU utilization, and depletes its entire CPUCreditBalance value of 122 credits. At the end of this period, with the CPUCreditBalance at zero, CPU utilization is forced to drop to the baseline utilization level of 5%. At the baseline, the instance earns as many credits as it spends.

P6 – For the next 14 hours, CPU utilization is at 5% (the baseline). The instance earns as many credits as it spends. The CPUCreditBalance value remains at 0.

P7 – For the last 24 hours in this example, the instance is idle and CPU utilization is 0%. During this time, the instance earns 144 credits, which it accrues in its CPUCreditBalance.

Example 2: Explain credit use with T2 Standard

In this example, you see how a t2.nano instance launched as standard earns, accrues, and spends *launch* and *earned* credits. You see how the credit balance reflects not only accrued *earned* credits, but also accrued *launch* credits.

A t2.nano instance gets 30 launch credits when it is launched, and earns 72 credits every 24 hours. Its credit balance limit is 72 earned credits; launch credits do not count towards the limit. After the limit is reached, new credits that are earned are discarded. For more information about the number of credits that can be earned and accrued, see the [credit table \(p. 250\)](#). For more information about limits, see [Launch credit limits \(p. 262\)](#).

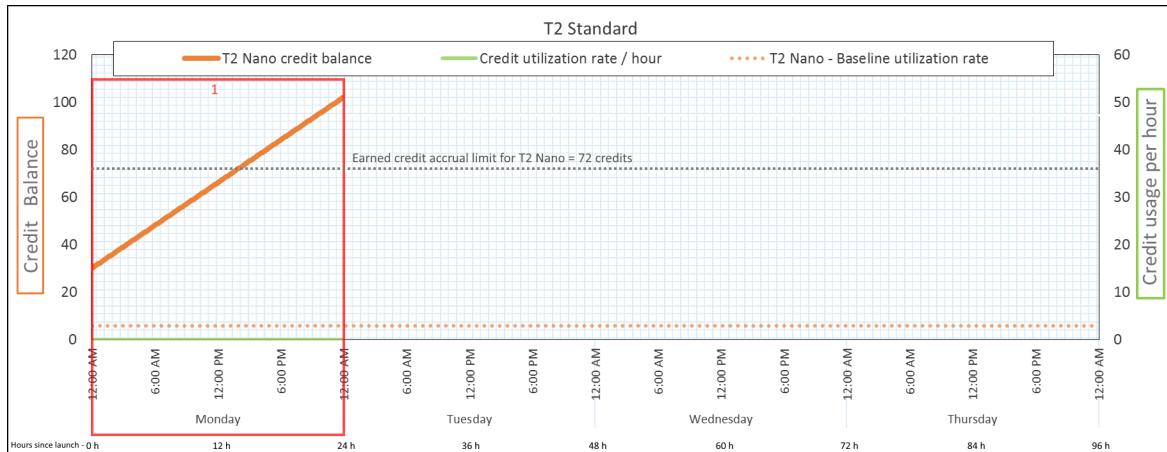

You might launch a T2 Standard instance and use it immediately. Or, you might launch a T2 Standard instance and leave it idle for a few days before running applications on it. Whether an instance is used or remains idle determines if credits are spent or accrued. If an instance remains idle for 24 hours from the time it is launched, the credit balance appears to exceed its limit because the balance reflects both accrued earned credits and accrued launch credits. However, after CPU is used, the launch credits are spent first. Thereafter, the limit always reflects the maximum number of earned credits that can be accrued.

This example describes an instance that remains idle for 24 hours from the time it is launched, and walks you through seven periods of time over a 96-hour period, showing the rate at which credits are earned, accrued, spent, and discarded, and the value of the credit balance at the end of each period.

Period 1: 1 – 24 hours

At 0 hours on the graph, the T2 instance is launched as standard and immediately gets 30 launch credits. It earns credits while in the running state. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. At approximately 14 hours after launch, the credit balance is 72 (30 launch credits + 42 earned credits), which is equivalent to what the instance can earn in 24 hours. At 24 hours after launch, the credit balance exceeds 72 credits because the unspent launch credits are accrued in the credit balance—the credit balance is 102 credits: 30 launch credits + 72 earned credits.

Amazon Elastic Compute Cloud
User Guide for Windows Instances
General purpose

Credit Spend Rate	0 credits per 24 hours (0% CPU utilization)
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	0 credits per 24 hours
Credit Balance	102 credits (30 launch credits + 72 earned credits)

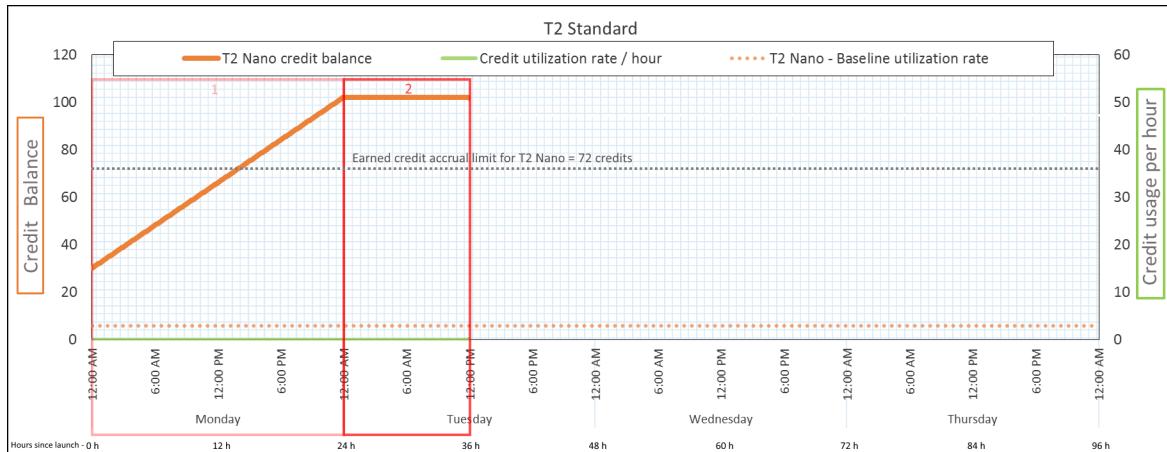

Conclusion

If there is no CPU utilization after launch, the instance accrues more credits than what it can earn in 24 hours (30 launch credits + 72 earned credits = 102 credits).

In a real-world scenario, an EC2 instance consumes a small number of credits while launching and running, which prevents the balance from reaching the maximum theoretical value in this example.

Period 2: 25 – 36 hours

For the next 12 hours, the instance continues to remain idle and earn credits, but the credit balance does not increase. It plateaus at 102 credits (30 launch credits + 72 earned credits). The credit balance has reached its limit of 72 accrued earned credits, so newly earned credits are discarded.

Credit Spend Rate	0 credits per 24 hours (0% CPU utilization)
-------------------	---------------------------------------------

Credit Earn Rate	72 credits per 24 hours (3 credits per hour)
Credit Discard Rate	72 credits per 24 hours (100% of credit earn rate)
Credit Balance	102 credits (30 launch credits + 72 earned credits) —balance is unchanged

Conclusion

An instance constantly earns credits, but it cannot accrue more earned credits if the credit balance has reached its limit. After the limit is reached, newly earned credits are discarded. Launch credits do not count towards the credit balance limit. If the balance includes accrued launch credits, the balance appears to be over the limit.

Period 3: 37 – 61 hours

For the next 25 hours, the instance uses 2% CPU, which requires 30 credits. In the same period, it earns 75 credits, but the credit balance decreases. The balance decreases because the accrued *launch* credits are spent first, while newly earned credits are discarded because the credit balance is already at its limit of 72 earned credits.

Credit Spend Rate	28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—30 credits over 25 hours
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	72 credits per 24 hours (100% of credit earn rate)
Credit Balance	72 credits (30 launch credits were spent; 72 earned credits remain unspent)

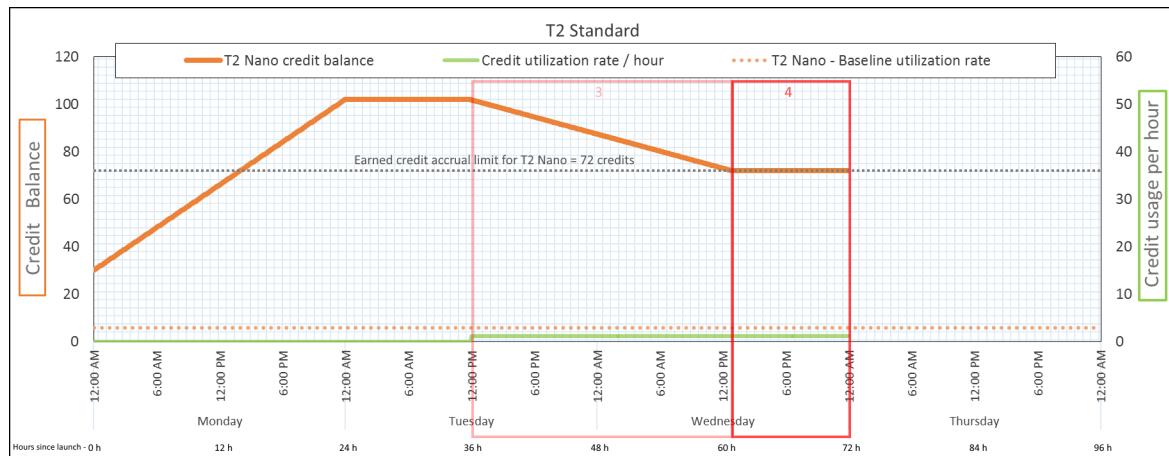

Conclusion

An instance spends launch credits first, before spending earned credits. Launch credits do not count towards the credit limit. After the launch credits are spent, the balance can never go higher than what can be earned in 24 hours. Furthermore, while an instance is running, it cannot get more launch credits.

Period 4: 62 – 72 hours

For the next 11 hours, the instance uses 2% CPU, which requires 13.2 credits. This is the same CPU utilization as in the previous period, but the balance does not decrease. It stays at 72 credits.

The balance does not decrease because the credit earn rate is higher than the credit spend rate. In the time that the instance spends 13.2 credits, it also earns 33 credits. However, the balance limit is 72 credits, so any earned credits that exceed the limit are discarded. The balance plateaus at 72 credits, which is different from the plateau of 102 credits during Period 2, because there are no accrued launch credits.

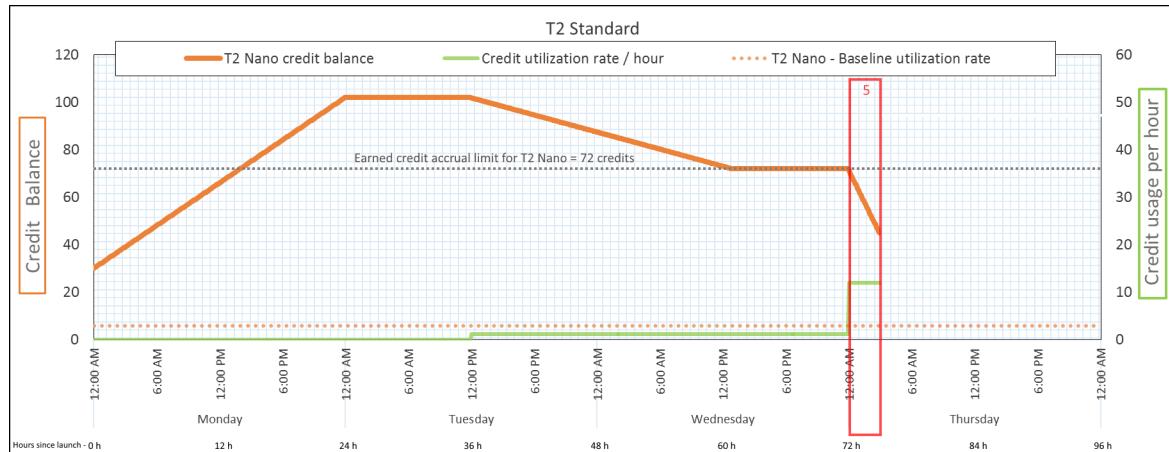

Credit Spend Rate	28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—13.2 credits over 11 hours
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	43.2 credits per 24 hours (60% of credit earn rate)
Credit Balance	72 credits (0 launch credits, 72 earned credits)—balance is at its limit

Conclusion

After launch credits are spent, the credit balance limit is determined by the number of credits that an instance can earn in 24 hours. If the instance earns more credits than it spends, newly earned credits over the limit are discarded.

Period 5: 73 – 75 hours

For the next three hours, the instance bursts at 20% CPU utilization, which requires 36 credits. The instance earns nine credits in the same three hours, which results in a net balance decrease of 27 credits. At the end of three hours, the credit balance is 45 accrued earned credits.

Credit Spend Rate	288 credits per 24 hours (12 credits per hour, 20% CPU utilization, 400% of credit earn rate)—36 credits over 3 hours
Credit Earn Rate	72 credits per 24 hours (9 credits over 3 hours)
Credit Discard Rate	0 credits per 24 hours
Credit Balance	45 credits (previous balance (72) - spent credits (36) + earned credits (9))—balance decreases at a rate of 216 credits per 24 hours (spend rate 288/24 + earn rate 72/24 = balance decrease rate 216/24)

Conclusion

If an instance spends more credits than it earns, its credit balance decreases.

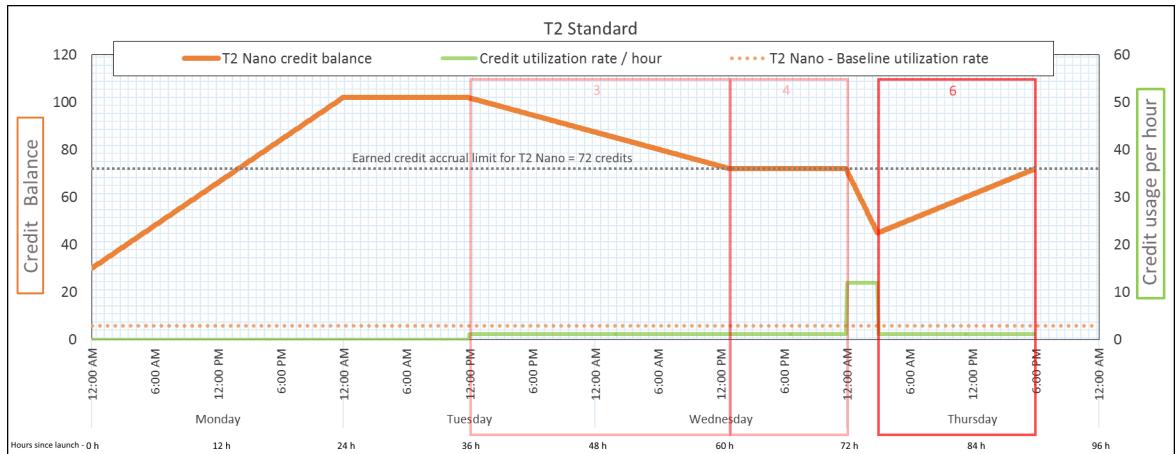

Period 6: 76 – 90 hours

For the next 15 hours, the instance uses 2% CPU, which requires 18 credits. This is the same CPU utilization as in Periods 3 and 4. However, the balance increases in this period, whereas it decreased in Period 3 and plateaued in Period 4.

In Period 3, the accrued launch credits were spent, and any earned credits that exceeded the credit limit were discarded, resulting in a decrease in the credit balance. In Period 4, the instance spent fewer credits than it earned. Any earned credits that exceeded the limit were discarded, so the balance plateaued at its maximum of 72 credits.

In this period, there are no accrued launch credits, and the number of accrued earned credits in the balance is below the limit. No earned credits are discarded. Furthermore, the instance earns more credits than it spends, resulting in an increase in the credit balance.

Amazon Elastic Compute Cloud
User Guide for Windows Instances
General purpose

Credit Spend Rate	28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—18 credits over 15 hours
Credit Earn Rate	72 credits per 24 hours (45 credits over 15 hours)
Credit Discard Rate	0 credits per 24 hours
Credit Balance	72 credits (balance increases at a rate of 43.2 credits per 24 hours—change rate = spend rate 28.8/24 + earn rate 72/24)

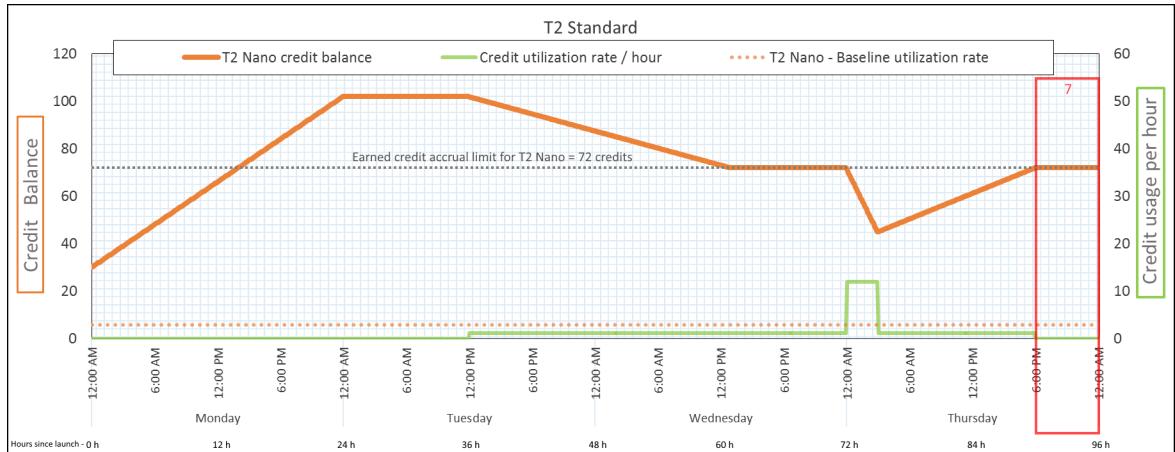

Conclusion

If an instance spends fewer credits than it earns, its credit balance increases.

Period 7: 91 – 96 hours

For the next six hours, the instance remains idle—CPU utilization is 0%—and no credits are spent. This is the same CPU utilization as in Period 2, but the balance does not plateau at 102 credits—it plateaus at 72 credits, which is the credit balance limit for the instance.

In Period 2, the credit balance included 30 accrued launch credits. The launch credits were spent in Period 3. A running instance cannot get more launch credits. After its credit balance limit is reached, any earned credits that exceed the limit are discarded.

Credit Spend Rate	0 credits per 24 hours (0% CPU utilization)
Credit Earn Rate	72 credits per 24 hours
Credit Discard Rate	72 credits per 24 hours (100% of credit earn rate)
Credit Balance	72 credits (0 launch credits, 72 earned credits)

Conclusion

An instance constantly earns credits, but cannot accrue more earned credits if the credit balance limit has been reached. After the limit is reached, newly earned credits are discarded. The credit balance limit is determined by the number of credits that an instance can earn in 24 hours. For more information about credit balance limits, see the [credit table \(p. 250\)](#).

Work with burstable performance instances

The steps for launching, monitoring, and modifying these instances are similar. The key difference is the default credit specification when they launch.

Each burstable performance instance family comes with the following *default credit specification*:

- T3a and T3 instances launch as **unlimited**
- T3 instances on a Dedicated Host can only launch as **standard**
- T2 instances launch as **standard**

You can [change the default credit specification \(p. 274\)](#) for the account.

Contents

- [Launch a burstable performance instance as Unlimited or Standard \(p. 270\)](#)
- [Use an Auto Scaling group to launch a burstable performance instance as Unlimited \(p. 271\)](#)
- [View the credit specification of a burstable performance instance \(p. 273\)](#)
- [Modify the credit specification of a burstable performance instance \(p. 273\)](#)
- [Set the default credit specification for the account \(p. 274\)](#)
- [View the default credit specification \(p. 275\)](#)

Launch a burstable performance instance as Unlimited or Standard

You can launch your instances as **unlimited** or **standard** using the Amazon EC2 console, an AWS SDK, a command line tool, or with an Auto Scaling group. For more information, see [Use an Auto Scaling group to launch a burstable performance instance as Unlimited \(p. 271\)](#).

Console

To launch a burstable performance instance as Unlimited or Standard

1. Follow the procedure to [launch an instance \(p. 554\)](#).
2. Under **Instance type**, select a T instance type.
3. Expand **Advanced details**, and for **Credit specification**, select a credit specification. If you do not make a selection, the default is used, which is **standard** for T2, and **unlimited** for T3a and T3.
4. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an instance using the new launch instance wizard \(p. 552\)](#).

AWS CLI

To launch a burstable performance instance as Unlimited or Standard

Use the [run-instances](#) command to launch your instances. Specify the credit specification using the `--credit-specification CpuCredits=` parameter. Valid credit specifications are unlimited and standard.

- For T3a and T3, if you do not include the `--credit-specification` parameter, the instance launches as unlimited by default.
- For T2, if you do not include the `--credit-specification` parameter, the instance launches as standard by default.

```
aws ec2 run-instances \
--image-id ami-abc12345 \
--count 1 \
--instance-type t3.micro \
--key-name MyKeyPair \
--credit-specification "CpuCredits=unlimited"
```

Use an Auto Scaling group to launch a burstable performance instance as Unlimited

When burstable performance instances are launched or started, they require CPU credits for a good bootstrapping experience. If you use an Auto Scaling group to launch your instances, we recommend that you configure your instances as unlimited. If you do, the instances use surplus credits when they are automatically launched or restarted by the Auto Scaling group. Using surplus credits prevents performance restrictions.

Create a launch template

You must use a *launch template* for launching instances as unlimited in an Auto Scaling group. A launch configuration does not support launching instances as unlimited.

Note

unlimited mode is not supported for T3 instances that are launched on a Dedicated Host.

Console

To create a launch template that launches instances as Unlimited

1. Follow the [Creating a Launch Template for an Auto Scaling Group](#) procedure.
2. In **Launch template contents**, for **Instance type**, choose an instance size.
3. To launch instances as unlimited in an Auto Scaling group, under **Advanced details**, for **Credit specification**, choose **Unlimited**.
4. When you've finished defining the launch template parameters, choose **Create launch template**. For more information, see [Creating a Launch Template for an Auto Scaling Group](#) in the *Amazon EC2 Auto Scaling User Guide*.

AWS CLI

To create a launch template that launches instances as Unlimited

Use the [create-launch-template](#) command and specify unlimited as the credit specification.

- For T3a and T3, if you do not include the `CreditSpecification={CpuCredits=unlimited}` value, the instance launches as unlimited by default.

- For T2, if you do not include the `CreditSpecification={CpuCredits=unlimited}` value, the instance launches as standard by default.

```
aws ec2 create-launch-template \
--launch-template-name MyLaunchTemplate \
--version-description FirstVersion \
--launch-template-data
ImageId=ami-8c1be5f6,InstanceType=t3.medium,CreditSpecification={CpuCredits=unlimited}
```

Associate an Auto Scaling group with a launch template

To associate the launch template with an Auto Scaling group, create the Auto Scaling group using the launch template, or add the launch template to an existing Auto Scaling group.

Console

To create an Auto Scaling group using a launch template

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation bar at the top of the screen, select the same Region that you used when you created the launch template.
3. In the navigation pane, choose **Auto Scaling Groups**, **Create Auto Scaling group**.
4. Choose **Launch Template**, select your launch template, and then choose **Next Step**.
5. Complete the fields for the Auto Scaling group. When you've finished reviewing your configuration settings on the **Review page**, choose **Create Auto Scaling group**. For more information, see [Creating an Auto Scaling Group Using a Launch Template](#) in the *Amazon EC2 Auto Scaling User Guide*.

AWS CLI

To create an Auto Scaling group using a launch template

Use the [create-auto-scaling-group](#) AWS CLI command and specify the `--launch-template` parameter.

Console

To add a launch template to an existing Auto Scaling group

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation bar at the top of the screen, select the same Region that you used when you created the launch template.
3. In the navigation pane, choose **Auto Scaling Groups**.
4. From the Auto Scaling group list, select an Auto Scaling group, and choose **Actions**, **Edit**.
5. On the **Details** tab, for **Launch Template**, choose a launch template, and then choose **Save**.

AWS CLI

To add a launch template to an existing Auto Scaling group

Use the [update-auto-scaling-group](#) AWS CLI command and specify the `--launch-template` parameter.

View the credit specification of a burstable performance instance

You can view the credit specification (unlimited or standard) of a running or stopped instance.

Console

To view the credit specification of a burstable instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Details** and view the **Credit specification** field. The value is either unlimited or standard.

AWS CLI

To describe the credit specification of a burstable performance instance

Use the [describe-instance-credit-specifications](#) command. If you do not specify one or more instance IDs, all instances with the credit specification of unlimited are returned, as well as instances that were previously configured with the unlimited credit specification. For example, if you resize a T3 instance to an M4 instance, while it is configured as unlimited, Amazon EC2 returns the M4 instance.

```
aws ec2 describe-instance-credit-specifications --instance-id i-1234567890abcdef0
```

The following is example output.

```
{  
    "InstanceCreditSpecifications": [  
        {  
            "InstanceId": "i-1234567890abcdef0",  
            "CpuCredits": "unlimited"  
        }  
    ]  
}
```

Modify the credit specification of a burstable performance instance

You can switch the credit specification of a running or stopped instance at any time between unlimited and standard.

Note that in unlimited mode, an instance can spend surplus credits, which might incur an additional charge. For more information, see [Surplus credits can incur charges \(p. 256\)](#).

Console

To modify the credit specification of a burstable performance instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**.
3. Select the instance. To modify the credit specification for several instances at one time, select all applicable instances.
4. Choose **Actions, Instance settings, Change credit specification**. This option is enabled only if you selected a burstable performance instance.

5. To change the credit specification to unlimited, select the check box next to the instance ID.
To change the credit specification to standard, clear the check box next to the instance ID.

AWS CLI

To modify the credit specification of a burstable performance instance (AWS CLI)

Use the [modify-instance-credit-specification](#) command. Specify the instance and its credit specification using the --instance-credit-specification parameter. Valid credit specifications are unlimited and standard.

```
aws ec2 modify-instance-credit-specification \
    --region us-east-1 \
    --instance-credit-specification
    "InstanceId=i-1234567890abcdef0,CpuCredits=unlimited"
```

The following is example output.

```
{
    "SuccessfulInstanceCreditSpecifications": [
        {
            "InstanceId": "i- 1234567890abcdef0"
        }
    ],
    "UnsuccessfulInstanceCreditSpecifications": []
}
```

Set the default credit specification for the account

Each burstable performance instance family comes with a [default credit specification \(p. 270\)](#). You can change the default credit specification for each burstable performance instance family at the account level per AWS Region.

If you use the launch instance wizard in the EC2 console to launch instances, the value you select for the credit specification overrides the account-level default credit specification. If you use the AWS CLI to launch instances, all new burstable performance instances in the account launch using the default credit specification. The credit specification for existing running or stopped instances is not affected.

Consideration

The default credit specification for an instance family can be modified only once in a rolling 5-minute period, and up to four times in a rolling 24-hour period.

Console

To set the default credit specification at the account level per Region

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. On the left navigation pane, choose **EC2 Dashboard**.
4. From **Account attributes**, choose **Default credit specification**.
5. Choose **Manage**.
6. For each instance family, choose **Unlimited** or **Standard**, and then choose **Update**.

AWS CLI

To set the default credit specification at the account level (AWS CLI)

Use the [modify-default-credit-specification](#) command. Specify the AWS Region, instance family, and the default credit specification using the --cpu-credits parameter. Valid default credit specifications are unlimited and standard.

```
aws ec2 modify-default-credit-specification \
--region us-east-1 \
--instance-family t2 \
--cpu-credits unlimited
```

View the default credit specification

You can view the default credit specification of a burstable performance instance family at the account level per AWS Region.

Console

To view the default credit specification at the account level (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. On the left navigation pane, choose **EC2 Dashboard**.
4. From **Account attributes**, choose **Default credit specification**.

AWS CLI

To view the default credit specification at the account level (AWS CLI)

Use the [get-default-credit-specification](#) command. Specify the AWS Region and instance family.

```
aws ec2 get-default-credit-specification --region us-east-1 --instance-family t2
```

Monitor your CPU credits for burstable performance instances

EC2 sends metrics to Amazon CloudWatch. You can see the CPU credit metrics in the Amazon EC2 per-instance metrics of the CloudWatch console or by using the AWS CLI to list the metrics for each instance. For more information, see [List metrics using the console \(p. 1195\)](#) and [List metrics using the AWS CLI \(p. 1197\)](#).

Contents

- [Additional CloudWatch metrics for burstable performance instances \(p. 275\)](#)
- [Calculate CPU credit usage \(p. 277\)](#)

Additional CloudWatch metrics for burstable performance instances

Burstable performance instances have these additional CloudWatch metrics, which are updated every five minutes:

- CPUCreditUsage – The number of CPU credits spent during the measurement period.
- CPUCreditBalance – The number of CPU credits that an instance has accrued. This balance is depleted when the CPU bursts and CPU credits are spent more quickly than they are earned.
- CPUSurplusCreditBalance – The number of surplus CPU credits spent to sustain CPU utilization when the CPUCreditBalance value is zero.

- **CPUSurplusCreditsCharged** – The number of surplus CPU credits exceeding the [maximum number of CPU credits \(p. 250\)](#) that can be earned in a 24-hour period, and thus attracting an additional charge.

The last two metrics apply only to instances configured as unlimited.

The following table describes the CloudWatch metrics for burstable performance instances. For more information, see [List the available CloudWatch metrics for your instances \(p. 1185\)](#).

Metric	Description
CPUCreditUsage	<p>The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100% utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes).</p> <p>CPU credit metrics are available at a five-minute frequency only. If you specify a period greater than five minutes, use the Sum statistic instead of the Average statistic.</p> <p>Units: Credits (vCPU-minutes)</p>
CPUCreditBalance	<p>The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the CPUCreditBalance also includes the number of launch credits that have been accrued.</p> <p>Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits do not count towards the limit.</p> <p>The credits in the CPUCreditBalance are available for the instance to spend to burst beyond its baseline CPU utilization.</p> <p>When an instance is running, credits in the CPUCreditBalance do not expire. When a T3a or T3 instance stops, the CPUCreditBalance value persists for seven days. Thereafter, all accrued credits are lost. When a T2 instance stops, the CPUCreditBalance value does not persist, and all accrued credits are lost.</p> <p>CPU credit metrics are available at a five-minute frequency only.</p> <p>Units: Credits (vCPU-minutes)</p>
CPUSurplusCreditBalance	<p>The number of surplus credits that have been spent by an unlimited instance when its CPUCreditBalance value is zero.</p> <p>The CPUSurplusCreditBalance value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the instance can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge.</p>

Metric	Description
	Units: Credits (vCPU-minutes)
CPUSurplusCreditsCharged	<p>The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge.</p> <p>Spent surplus credits are charged when any of the following occurs:</p> <ul style="list-style-type: none"> • The spent surplus credits exceed the maximum number of credits that the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour. • The instance is stopped or terminated. • The instance is switched from unlimited to standard.
	Units: Credits (vCPU-minutes)

Calculate CPU credit usage

The CPU credit usage of instances is calculated using the instance CloudWatch metrics described in the preceding table.

Amazon EC2 sends the metrics to CloudWatch every five minutes. A reference to the *prior* value of a metric at any point in time implies the previous value of the metric, sent *five minutes ago*.

Calculate CPU credit usage for Standard instances

- The CPU credit balance increases if CPU utilization is below the baseline, when the credits spent are less than the credits earned in the prior five-minute interval.
- The CPU credit balance decreases if CPU utilization is above the baseline, when the credits spent are more than the credits earned in the prior five-minute interval.

Mathematically, this is captured by the following equation:

Example

```
CPUCreditBalance = prior CPUCreditBalance + [Credits earned per hour * (5/60) - CPUCreditUsage]
```

The size of the instance determines the number of credits that the instance can earn per hour and the number of earned credits that it can accrue in the credit balance. For information about the number of credits earned per hour, and the credit balance limit for each instance size, see the [credit table \(p. 250\)](#).

Example

This example uses a t3.nano instance. To calculate the CPUCreditBalance value of the instance, use the preceding equation as follows:

- CPUCreditBalance – The current credit balance to calculate.
- prior CPUCreditBalance – The credit balance five minutes ago. In this example, the instance had accrued two credits.
- Credits earned per hour – A t3.nano instance earns six credits per hour.
- 5/60 – Represents the five-minute interval between CloudWatch metric publication. Multiply the credits earned per hour by 5/60 (five minutes) to get the number of credits that the instance earned in the past five minutes. A t3.nano instance earns 0.5 credits every five minutes.

- **CPUCreditUsage** – How many credits the instance spent in the past five minutes. In this example, the instance spent one credit in the past five minutes.

Using these values, you can calculate the CPUCreditBalance value:

Example

```
CPUCreditBalance = 2 + [0.5 - 1] = 1.5
```

Calculate CPU credit usage for Unlimited instances

When a burstable performance instance needs to burst above the baseline, it always spends accrued credits before spending surplus credits. When it depletes its accrued CPU credit balance, it can spend surplus credits to burst CPU for as long as it needs. When CPU utilization falls below the baseline, surplus credits are always paid down before the instance accrues earned credits.

We use the term **Adjusted balance** in the following equations to reflect the activity that occurs in this five-minute interval. We use this value to arrive at the values for the CPUCreditBalance and CPUSurplusCreditBalance CloudWatch metrics.

Example

```
Adjusted balance = [prior CPUCreditBalance - prior CPUSurplusCreditBalance] + [Credits earned per hour * (5/60) - CPUCreditUsage]
```

A value of **0** for **Adjusted balance** indicates that the instance spent all its earned credits for bursting, and no surplus credits were spent. As a result, both CPUCreditBalance and CPUSurplusCreditBalance are set to **0**.

A positive **Adjusted balance** value indicates that the instance accrued earned credits, and previous surplus credits, if any, were paid down. As a result, the **Adjusted balance** value is assigned to CPUCreditBalance, and the CPUSurplusCreditBalance is set to **0**. The instance size determines the [maximum number of credits \(p. 250\)](#) that it can accrue.

Example

```
CPUCreditBalance = min [max earned credit balance, Adjusted balance]  
CPUSurplusCreditBalance = 0
```

A negative **Adjusted balance** value indicates that the instance spent all its earned credits that it accrued and, in addition, also spent surplus credits for bursting. As a result, the **Adjusted balance** value is assigned to CPUSurplusCreditBalance and CPUCreditBalance is set to **0**. Again, the instance size determines the [maximum number of credits \(p. 250\)](#) that it can accrue.

Example

```
CPUSurplusCreditBalance = min [max earned credit balance, -Adjusted balance]  
CPUCreditBalance = 0
```

If the surplus credits spent exceed the maximum credits that the instance can accrue, the surplus credit balance is set to the maximum, as shown in the preceding equation. The remaining surplus credits are charged as represented by the CPUSurplusCreditsCharged metric.

Example

```
CPUSurplusCreditsCharged = max [-Adjusted balance - max earned credit balance, 0]
```

Finally, when the instance terminates, any surplus credits tracked by the `CPUSurplusCreditBalance` are charged. If the instance is switched from unlimited to standard, any remaining `CPUSurplusCreditBalance` is also charged.

Compute optimized instances

Compute optimized instances are ideal for compute-bound applications that benefit from high-performance processors.

C5 and C5n instances

These instances are well suited for the following:

- Batch processing workloads
- Media transcoding
- High-performance web servers
- High-performance computing (HPC)
- Scientific modeling
- Dedicated gaming servers and ad serving engines
- Machine learning inference and other compute-intensive applications

Bare metal instances, such as `c5.meta1`, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 C5 Instances](#).

C6i and C6id instances

These instances are ideal for running advanced, compute-intensive workloads, such as the following:

- High-performance computing (HPC)
- Batch processing
- Ad serving
- Video encoding
- Distributed analytics
- Highly scalable multiplayer gaming

C6in instances

These instances are well suited for compute-intensive workloads such as the following:

- Distributed computing applications
- Network virtual appliances
- Data analytics
- High Performance Computing (HPC)
- CPU-based AI/ML

For more information, see [Amazon EC2 C6i Instances](#).

C7g and C7gd instances

These instances are powered by AWS Graviton3 processors and are ideal for running advanced, compute-intensive workloads, such as the following:

- High-performance computing (HPC)
- Batch processing
- Ad serving
- Video encoding
- Gaming servers
- Scientific modeling
- Distributed analytics

For more information, see [Amazon EC2 C7g instances](#).

C7gn instances

Featuring the new AWS Nitro Cards, C7gn instances deliver the highest network bandwidth, and the best packet-processing performance for Graviton-based Amazon EC2 instances. C7gn instances offer up to 200 Gbps network bandwidth and up to 50 percent higher packet-processing performance compared to previous generation C6gn instances. C7gn instances are ideal for network-intensive workloads, including:

- Network virtual appliance workloads
- Data-intensive workloads, such as data analytics
- CPU-based artificial intelligence and machine learning (AI/ML) inference workloads

For more information, see [Amazon EC2 C7gn instances](#).

Hpc7g instances

Hpc7g instances are powered by AWS Graviton3E processors and the next generation AWS Nitro Card. They deliver 200 Gbps advanced networking with Elastic Fabric Adapter (EFA) for low latency and high network performance.

Hpc7g instances are ideal for running compute-intensive HPC applications that benefit from compute and memory bandwidth performance and low network latency, such as computational fluid dynamics, molecular dynamics, and weather simulations.

For more information, see [Amazon EC2 Hpc7g instances](#).

Hpc7a instances

These instances feature up to 300 Gbps networking bandwidth with Amazon EFS for low latency and high network performance with Message Passing Interface (MPI). The feature up to 192 CPU cores with up to 768 GB of system memory.

Hpc7a instances are ideal for running compute-intensive HPC applications, such as computational fluid dynamics, molecular dynamics, and weather simulations that benefit from large core counts per instance and low network latency.

For more information, see [Amazon EC2 Hpc7a instances](#).

Hardware specifications

The following is a summary of the hardware specifications for compute optimized instances. A virtual central processing unit (vCPU) represents a portion of the physical CPU assigned to a virtual machine (VM). For x86 instances, there are two vCPUs per core. For Graviton instances, there is one vCPU per core.

Instance type	Default vCPUs	Memory (GiB)
c1.medium	2	1.70
c1.xlarge	8	7.00
c3.large	2	3.75
c3.xlarge	4	7.50
c3.2xlarge	8	15.00
c3.4xlarge	16	30.00
c3.8xlarge	32	60.00
c4.large	2	3.75
c4.xlarge	4	7.50
c4.2xlarge	8	15.00
c4.4xlarge	16	30.00
c4.8xlarge	36	60.00
c5.large	2	4.00
c5.xlarge	4	8.00
c5.2xlarge	8	16.00
c5.4xlarge	16	32.00
c5.9xlarge	36	72.00
c5.12xlarge	48	96.00
c5.18xlarge	72	144.00

hpc7a.48xlarge	96	768.00
hpc7a.96xlarge	192	768.00

The compute optimized instances use the following processors.

AMD processors

- **2nd generation AMD EPYC processors (AMD EPYC 7R32):** C5a, C5ad
- **3rd generation AMD EPYC processors (AMD EPYC 7R13):** C6a, Hpc6a
- **4th generation AMD EPYC processors (AMD EPYC 9R14):** Hpc7a

Intel processors

- **Intel Xeon Scalable processors (Haswell E5-2666 v3):** C4
- **Intel Xeon Scalable processors (Skylake 8124):** C5n
- **Intel Xeon Scalable processors (Skylake 8124M or Cascade Lake 8223CL):** Smaller C5 and C5d
- **2nd generation Intel Xeon Scalable processors (Cascade Lake 8275CL):** Larger C5 and C5d
- **3rd generation Intel Xeon Scalable processors (Ice Lake 8375C):** C6i, C6id

For more information, see [Amazon EC2 Instance Types](#).

Instance performance

EBS-optimized instances enable you to get consistently high performance for your EBS volumes by eliminating contention between Amazon EBS I/O and other network traffic from your instance. Some compute optimized instances are EBS-optimized by default at no additional cost. For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).

Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see [Enhanced networking on Windows \(p. 1326\)](#).

The following is a summary of network performance for compute optimized instances that support enhanced networking.

Note

Instance types indicated with a † have a baseline bandwidth and can use a network I/O credit mechanism to burst beyond their baseline bandwidth on a best effort basis. For more information, see [instance network bandwidth \(p. 1324\)](#).

Instance type	Network performance	Enhanced networking features
c1.medium	Moderate	Not supported
c1.xlarge	High	Not supported
c3.large	Moderate	Not supported
c3.xlarge	Moderate	Not supported
c3.2xlarge	High	Not supported
c3.4xlarge	High	Not supported
c3.8xlarge	10 Gigabit	Not supported
c4.large	Moderate	Not supported
c4.xlarge	High	Not supported
c4.2xlarge	High	Not supported
c4.4xlarge	High	Not supported
c4.8xlarge	10 Gigabit	Not supported
c5.large †	Up to 10 Gigabit	ENI
c5.xlarge †	Up to 10 Gigabit	ENI
c5.2xlarge †	Up to 10 Gigabit	ENI
c5.4xlarge †	Up to 10 Gigabit	ENI
c5.9xlarge	12 Gigabit	ENI
c5.12xlarge	12 Gigabit	ENI
c5.18xlarge	25 Gigabit	ENI
c5.24xlarge	25 Gigabit	ENI
c5.metal	25 Gigabit	ENI
c5a.large †	Up to 10 Gigabit	ENI
c5a.xlarge †	Up to 10 Gigabit	ENI
c5a.2xlarge †	Up to 10 Gigabit	ENI
c5a.4xlarge †	Up to 10 Gigabit	ENI
c5a.8xlarge	10 Gigabit	ENI
c5a.12xlarge	12 Gigabit	ENI
c5a.16xlarge	20 Gigabit	ENI

Instance type	Network performance	Enhanced networking features
c5a.24xlarge	20 Gigabit	ENI
c5ad.large †	Up to 10 Gigabit	ENI
c5ad.xlarge †	Up to 10 Gigabit	ENI
c5ad.2xlarge †	Up to 10 Gigabit	ENI
c5ad.4xlarge †	Up to 10 Gigabit	ENI
c5ad.8xlarge	10 Gigabit	ENI
c5ad.12xlarge	12 Gigabit	ENI
c5ad.16xlarge	20 Gigabit	ENI
c5ad.24xlarge	20 Gigabit	ENI
c5d.large †	Up to 10 Gigabit	ENI
c5d.xlarge †	Up to 10 Gigabit	ENI
c5d.2xlarge †	Up to 10 Gigabit	ENI
c5d.4xlarge †	Up to 10 Gigabit	ENI
c5d.9xlarge	12 Gigabit	ENI
c5d.12xlarge	12 Gigabit	ENI
c5d.18xlarge	25 Gigabit	ENI
c5d.24xlarge	25 Gigabit	ENI
c5d.metal	25 Gigabit	ENI
c5n.large †	Up to 25 Gigabit	ENI
c5n.xlarge †	Up to 25 Gigabit	ENI
c5n.2xlarge †	Up to 25 Gigabit	ENI
c5n.4xlarge †	Up to 25 Gigabit	ENI
c5n.9xlarge	50 Gigabit	ENI EFA
c5n.18xlarge	100 Gigabit	ENI EFA
c5n.metal	100 Gigabit	ENI EFA
c6a.large †	Up to 12.5 Gigabit	ENI
c6a.xlarge †	Up to 12.5 Gigabit	ENI
c6a.2xlarge †	Up to 12.5 Gigabit	ENI
c6a.4xlarge †	Up to 12.5 Gigabit	ENI
c6a.8xlarge	12.5 Gigabit	ENI
c6a.12xlarge	18.75 Gigabit	ENI

Instance type	Network performance	Enhanced networking features
c6a.16xlarge	25 Gigabit	ENI
c6a.24xlarge	37.5 Gigabit	ENI
c6a.32xlarge	50 Gigabit	ENI
c6a.48xlarge	50 Gigabit	ENI EFA
c6a.metal	50 Gigabit	ENI EFA
c6i.large †	Up to 12.5 Gigabit	ENI
c6i.xlarge †	Up to 12.5 Gigabit	ENI
c6i.2xlarge †	Up to 12.5 Gigabit	ENI
c6i.4xlarge †	Up to 12.5 Gigabit	ENI
c6i.8xlarge	12.5 Gigabit	ENI
c6i.12xlarge	18.75 Gigabit	ENI
c6i.16xlarge	25 Gigabit	ENI
c6i.24xlarge	37.5 Gigabit	ENI
c6i.32xlarge	50 Gigabit	ENI EFA
c6i.metal	50 Gigabit	ENI EFA
c6id.large †	Up to 12.5 Gigabit	ENI
c6id.xlarge †	Up to 12.5 Gigabit	ENI
c6id.2xlarge †	Up to 12.5 Gigabit	ENI
c6id.4xlarge †	Up to 12.5 Gigabit	ENI
c6id.8xlarge	12.5 Gigabit	ENI
c6id.12xlarge	18.75 Gigabit	ENI
c6id.16xlarge	25 Gigabit	ENI
c6id.24xlarge	37.5 Gigabit	ENI
c6id.32xlarge	50 Gigabit	ENI EFA
c6id.metal	50 Gigabit	ENI EFA
c6in.large †	Up to 25 Gigabit	ENI
c6in.xlarge †	Up to 30 Gigabit	ENI
c6in.2xlarge †	Up to 40 Gigabit	ENI
c6in.4xlarge †	Up to 50 Gigabit	ENI
c6in.8xlarge	50 Gigabit	ENI
c6in.12xlarge	75 Gigabit	ENI

Instance type	Network performance	Enhanced networking features
c6in.16xlarge	100 Gigabit	ENI
c6in.24xlarge	150 Gigabit	ENI
c6in.32xlarge	200 Gigabit	ENI EFA
c6in.metal	200 Gigabit	ENI EFA
hpc7a.12xlarge	300 Gigabit	ENI EFA
hpc7a.24xlarge	300 Gigabit	ENI EFA
hpc7a.48xlarge	300 Gigabit	ENI EFA
hpc7a.96xlarge	300 Gigabit	ENI EFA

For 32xlarge and metal instance types that support 200 Gbps, at least 2 ENIs, each attached to a different network card, are required on the instance to achieve 200 Gbps throughput. Each ENI attached to a network card can achieve a max of 170 Gbps.

The following table shows the baseline and burst bandwidth for instance types that use the network I/O credit mechanism to burst beyond their baseline bandwidth.

Instance type	Baseline bandwidth (Gbps)	Burst bandwidth (Gbps)
c5.large	0.75	10.0
c5.xlarge	1.25	10.0
c5.2xlarge	2.5	10.0
c5.4xlarge	5.0	10.0
c5a.large	0.75	10.0
c5a.xlarge	1.25	10.0
c5a.2xlarge	2.5	10.0
c5a.4xlarge	5.0	10.0
c5ad.large	0.75	10.0
c5ad.xlarge	1.25	10.0
c5ad.2xlarge	2.5	10.0
c5ad.4xlarge	5.0	10.0
c5d.large	0.75	10.0
c5d.xlarge	1.25	10.0
c5d.2xlarge	2.5	10.0
c5d.4xlarge	5.0	10.0
c5n.large	3.0	25.0

Instance type	Baseline bandwidth (Gbps)	Burst bandwidth (Gbps)
c5n.xlarge	5.0	25.0
c5n.2xlarge	10.0	25.0
c5n.4xlarge	15.0	25.0
c6a.large	0.781	12.5
c6a.xlarge	1.562	12.5
c6a.2xlarge	3.125	12.5
c6a.4xlarge	6.25	12.5
c6i.large	0.781	12.5
c6i.xlarge	1.562	12.5
c6i.2xlarge	3.125	12.5
c6i.4xlarge	6.25	12.5
c6id.large	0.781	12.5
c6id.xlarge	1.562	12.5
c6id.2xlarge	3.125	12.5
c6id.4xlarge	6.25	12.5
c6in.large	3.125	25.0
c6in.xlarge	6.25	30.0
c6in.2xlarge	12.5	40.0
c6in.4xlarge	25.0	50.0

Amazon EBS I/O performance

Amazon EBS optimized instances use an optimized configuration stack and provide additional, dedicated capacity for Amazon EBS I/O. This optimization provides the best performance for your Amazon EBS volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

For more information, see [Amazon EBS–optimized instances \(p. 1941\)](#).

SSD-based instance store volume I/O performance

If you use all the SSD-based instance store volumes available to your instance, you can get up to the IOPS (4,096 byte block size) performance listed in the following table (at queue depth saturation). Otherwise, you get lower IOPS performance.

Instance Size	100% Random Read IOPS	Write IOPS
c5ad.large	16,283	7,105
c5ad.xlarge	32,566	14,211

Instance Size	100% Random Read IOPS	Write IOPS
c5ad.2xlarge	65,132	28,421
c5ad.4xlarge	130,263	56,842
c5ad.8xlarge	260,526	113,684
c5ad.12xlarge	412,500	180,000
c5ad.16xlarge	521,053	227,368
c5ad.24xlarge	825,000	360,000
c5d.large	20,000	9,000
c5d.xlarge	40,000	18,000
c5d.2xlarge	80,000	37,000
c5d.4xlarge	175,000	75,000
c5d.9xlarge	350,000	170,000
c5d.12xlarge	700,000	340,000
c5d.18xlarge	700,000	340,000
c5d.24xlarge	1,400,000	680,000
c5d.metal	1,400,000	680,000
c6id.large	33,542	16,771
c6id.xlarge	67,083	33,542
c6id.2xlarge	134,167	67,084
c6id.4xlarge	268,333	134,167
c6id.8xlarge	536,666	268,334
c6id.12xlarge	804,999	402,501
c6id.16xlarge	1,073,332	536,668
c6id.24xlarge	1,609,998	805,002
c6id.32xlarge	2,146,664	1,073,336
c6id.metal	2,146,664	1,073,336

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called *over-provisioning*. The SSD-based instance store volumes provided to an instance don't have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see [Instance store volume TRIM support \(p. 2013\)](#).

Release notes

- C4 instances and instances built on the [Nitro System \(p. 218\)](#) require 64-bit EBS-backed HVM AMIs. They have high-memory and require a 64-bit operating system to take advantage of that capacity. HVM AMIs provide superior performance in comparison to paravirtual (PV) AMIs on high-memory instance types. In addition, you must use an HVM AMI to take advantage of enhanced networking.
- Instances built on the Nitro System have the following requirements:
 - [NVMe drivers \(p. 1939\)](#) must be installed
 - [Elastic Network Adapter \(ENA\) drivers \(p. 1327\)](#) must be installed

The current [AWS Windows AMIs \(p. 41\)](#) meet these requirements.

- To get the best performance from your C6i instances, ensure that they have ENA driver version 2.2.3 or later. Using an ENA driver earlier than version 2.0.0 with these instances causes network interface attachment failures. The following AMIs have a compatible ENA driver.
 - AWS Windows AMI from May 2021 or later
- The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. For more information, see [Instance volume limits \(p. 2019\)](#).
- Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.
- To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support.
- Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.
- There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see [How many instances can I run in Amazon EC2?](#) in the Amazon EC2 FAQ.

Memory optimized instances

Memory optimized instances are designed to deliver fast performance for workloads that process large data sets in memory.

R5, R5a, R5b, and R5n instances

These instances are well suited for the following:

- High-performance, including relational MySQL and NoSQL, for example MongoDB and Cassandra databases.

- Distributed web scale cache stores that provide in-memory caching of key-value type data, for example Memcached and Redis
- In-memory databases using optimized data storage formats and analytics for business intelligence; for example, SAP HANA
- Applications performing real-time processing of big unstructured data, using Hadoop and Spark clusters
- High-performance computing (HPC) and Electronic Design Automation (EDA) applications.

Bare metal instances, such as `r5.metal`, provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 R5 Instances](#).

R6a instances

These instances are ideal for running memory-intensive workloads, such as the following:

- High-performance databases, both relational and NoSQL
- Distributed web scale in-memory caches, such as Memcached and Redis
- Real-time big data analytics, such as Hadoop and Spark clusters

Hpc6id instances

These instances are ideal for running high performance computing (HPC) workloads, such as the following:

- Seismic and Reservoir
- Crash Simulation
- Finite Element Analysis

R6i and R6id instances

These instances are ideal for running memory-intensive workloads, such as the following:

- High-performance databases, relational and NoSQL
- In-memory databases, for example SAP HANA
- Distributed web scale in-memory caches, for example Memcached and Redis
- Real-time big data analytics, including Hadoop and Spark clusters

R6in and R6idn instances

These instances are well suited for network-intensive workloads such as the following:

- High-performance relational, MySQL and NoSQL. For example, MongoDB and Cassandra databases
- Distributed web scale cache stores that provide in-memory caching of key-value type data, including Memcached and Redis
- In-memory databases using optimized data storage formats and analytics for business intelligence, for example SAP HANA
- Real-time big data analytics for financial services, for example Hadoop and Spark clusters

For more information, see [Amazon EC2 R6i Instances](#).

R7g and R7gd instances

These instances are powered by AWS Graviton3 processors and are ideal for running memory-intensive workloads, such as the following:

- Open-source databases; for example, MySQL, MariaDB, and PostgreSQL
- In-memory caches; for example, Memcached, Redis, and KeyDB

For more information, see [Amazon EC2 R7g instances](#).

High memory (u-*) instances

These instances offer 3 TiB, 6 TiB, 9 TiB, 12 TiB, 18 TiB, and 24 TiB of memory per instance. They are designed to run large in-memory databases, including production deployments of the SAP HANA in-memory database.

For more information, see [Amazon EC2 High Memory Instances](#) and [Storage Configuration for SAP HANA](#). For information about supported operating systems, see [Migrating SAP HANA on AWS to an EC2 High Memory Instance](#).

X1 instances

These instances are well suited for the following:

- In-memory databases such as SAP HANA, including SAP-certified support for Business Suite S/4HANA, Business Suite on HANA (SoH), Business Warehouse on HANA (BW), and Data Mart Solutions on HANA. For more information, see [SAP HANA on the AWS Cloud](#).
- Big-data processing engines such as Apache Spark or Presto.
- High-performance computing (HPC) applications.

For more information, see [Amazon EC2 X1 Instances](#).

X1e instances

These instances are well suited for the following:

- High-performance databases.
- In-memory databases such as SAP HANA. For more information, see [SAP HANA on the AWS Cloud](#).
- Memory-intensive enterprise applications.

For more information, see [Amazon EC2 X1e Instances](#).

X2idn, X2iedn, and X2iezn instances

These instances are well suited for the following:

- In-memory databases, such as Redis and Memcached.
- Relational databases, such as MySQL and PostGreSQL.
- Electronic design automation (EDA) workloads, such as physical verification and layout tools.
- Memory-intensive workloads, such as real-time analytics and real-time caching servers.

X2idn and X2iedn instances support io2 Block Express volumes. All io2 volumes attached to X2idn and X2iedn instances, during or after launch, automatically run on EBS Block Express. For more information, see [io2 Block Express volumes](#).

For more information, see [Amazon EC2 X2i Instances](#).

z1d instances

These instances deliver both high compute and high memory and are well-suited for the following:

- Electronic Design Automation (EDA)
- Relational database workloads

`z1d.metal` instances provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 z1d Instances](#).

Hardware specifications

The following is a summary of the hardware specifications for memory optimized instances. A virtual central processing unit (vCPU) represents a portion of the physical CPU assigned to a virtual machine (VM). For x86 instances, there are two vCPUs per core. For Graviton instances, there is one vCPU per core.

Instance type	Default vCPUs	Memory (GiB)
hpc6id.32xlarge	64	1024.00
r3.large	2	15.00
r3.xlarge	4	30.50

* Each logical processor is a hyperthread on 224 cores.

The memory optimized instances use the following processors.

AMD processors

- **AMD EPYC 7000 series processors (AMD EPYC 7571):** R5a, R5ad
- **3rd generation AMD EPYC processors (AMD EPYC 7R13):** R6a

Intel processors

- **Intel Xeon Scalable processors (Haswell E7-8880 v3):** X1, X1e
- **Intel Xeon Scalable processors (Broadwell E5-2686 v4):** R4
- **Intel Xeon Scalable processors (Skylake 8151):** z1d
- **Intel Xeon Scalable processors (Skylake 8175M or Cascade Lake 8259CL):** R5, R5d
- **2nd generation Intel Xeon Scalable processors (Cascade Lake 8259CL):** R5b, R5n
- **2nd generation Intel Xeon Scalable processors (Cascade Lake 8252C):** X2iezn
- **3rd generation Intel Xeon Scalable processors (Ice Lake 8375C):** R6i, R6id, X2idn, X2iedn

For more information, see [Amazon EC2 Instance Types](#).

Memory performance

X1 instances include Intel Scalable Memory Buffers, providing 300 GiB/s of sustainable memory-read bandwidth and 140 GiB/s of sustainable memory-write bandwidth.

For more information about how much RAM can be enabled for memory optimized instances, see [Hardware specifications \(p. 294\)](#).

Memory optimized instances have high memory and require 64-bit HVM AMIs to take advantage of that capacity. HVM AMIs provide superior performance in comparison to paravirtual (PV) AMIs on memory optimized instances.

Instance performance

Memory optimized instances enable increased cryptographic performance through the latest Intel AES-NI feature and support Advanced Vector Extensions 2 (Intel AVX2) processor instructions to expand most integer commands to 256 bits.

Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see [Enhanced networking on Windows \(p. 1326\)](#).

The following is a summary of network performance for memory optimized instances that support enhanced networking.

Note

Instance types indicated with a † have a baseline bandwidth and can use a network I/O credit mechanism to burst beyond their baseline bandwidth on a best effort basis. For more information, see [instance network bandwidth \(p. 1324\)](#).

For 32xlarge and metal instance types that support 200 Gbps, at least 2 ENIs, each attached to a different network card, are required on the instance to achieve 200 Gbps throughput. Each ENI attached to a network card can achieve a max of 170 Gbps.

u-6tb1.metal, u-9tb1.metal, and u-12tb1.metal instances launched after March 12, 2020 provide network performance of 100 Gbps. u-6tb1.metal, u-9tb1.metal, and u-12tb1.metal instances launched before March 12, 2020 might only provide network performance of 25 Gbps. To ensure that instances launched before March 12, 2020 have a network performance of 100 Gbps, contact your account team to upgrade your instance at no additional cost.

The following table shows the baseline and burst bandwidth for instance types that use the network I/O credit mechanism to burst beyond their baseline bandwidth.

Instance type	Baseline bandwidth (Gbps)	Burst bandwidth (Gbps)
r4.large	0.75	10.0
r4.xlarge	1.25	10.0
r4.2xlarge	2.5	10.0
r4.4xlarge	5.0	10.0

Amazon EBS I/O performance

Amazon EBS optimized instances use an optimized configuration stack and provide additional, dedicated capacity for Amazon EBS I/O. This optimization provides the best performance for your Amazon EBS volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).

SSD-based instance store volume I/O performance

If you use all the SSD-based instance store volumes available to your instance, you can get up to the IOPS (4,096 byte block size) performance listed in the following table (at queue depth saturation). Otherwise, you get lower IOPS performance.

Instance Size	100% Random Read IOPS	Write IOPS
hpc6id.32xlarge	2,146,664	1,073,336
r5ad.large	30,000	15,000

z1d.metal	700,000	340,000

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called *over-provisioning*. The SSD-based instance store volumes provided to an instance don't have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see [Instance store volume TRIM support \(p. 2013\)](#).

High availability and reliability (X1)

X1 instances support Single Device Data Correction (SDDC +1), which detects and corrects multi-bit errors. SDDC +1 uses error checking and correction code to identify and disable a failed single DRAM device.

In addition, you can implement high availability (HA) and disaster recovery (DR) solutions to meet recovery point objective (RPO), recovery time objective (RTO), and cost requirements by leveraging [Amazon CloudFormation](#) and [Recover your instance \(p. 622\)](#).

If you run an SAP HANA production environment, you also have the option of using HANA System Replication (HSR) on X1 instances. For more information about architecting HA and DR solutions on X1 instances, see [SAP HANA on the Amazon Web Services Cloud: Quick Start Reference Deployment](#).

Support for vCPUs

Memory optimized instances provide a high number of vCPUs, which can cause launch issues with operating systems that have a lower vCPU limit. We strongly recommend that you use the latest AMIs when you launch memory optimized instances.

The following AMIs support launching memory optimized instances:

- Amazon Linux 2 (HVM)
- Amazon Linux AMI 2016.03 (HVM) or later
- Ubuntu Server 14.04 LTS (HVM)
- Red Hat Enterprise Linux 7.1 (HVM)
- SUSE Linux Enterprise Server 12 SP1 (HVM)
- Windows Server 2019
- Windows Server 2016
- Windows Server 2012 R2
- Windows Server 2012
- Windows Server 2008 R2 64-bit
- Windows Server 2008 SP2 64-bit

Release notes

- Instances built on the Nitro System have the following requirements:
 - [NVMe drivers \(p. 1939\)](#) must be installed
 - [Elastic Network Adapter \(ENA\) drivers \(p. 1327\)](#) must be installed

The current [AWS Windows AMIs \(p. 41\)](#) meet these requirements.

- To get the best performance from your R6i instances, ensure that they have ENA driver version 2.2.3 or later. Using an ENA driver earlier than version 2.0.0 with these instances causes network interface attachment failures. The following AMIs have a compatible ENA driver.
 - AWS Windows AMI from May 2021 or later
- The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. For more information, see [Instance volume limits \(p. 2019\)](#).
- All io2 volumes attached to C6a, C6in, C7g, C7gd, C7gn, Inf2, M6a, M6in, M6idn, M7a, M7g, M7gd, M7i, M7i-flex, P5, R5b, R6a, R6in, R6idn, R7g, R7gd, Trn1, Trn1n, X2idn, and X2iedn instances, during or after launch, automatically run on EBS Block Express. For more information, see [io2 Block Express volumes](#).
- Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.
- To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support.
- Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also

provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.

- You can't launch X1 instances using a Windows Server 2008 SP2 64-bit AMI, except for x1.16xlarge instances.
- You can't launch X1e instances using a Windows Server 2008 SP2 64-bit AMI.
- With earlier versions of the Windows Server 2008 R2 64-bit AMI, you can't launch r4.1.large and r4.4xlarge instances. If you experience this issue, update to the latest version of this AMI.
- There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see [How many instances can I run in Amazon EC2?](#) in the Amazon EC2 FAQ.

Storage optimized instances

Storage optimized instances are designed for workloads that require high, sequential read and write access to very large data sets on local storage. They are optimized to deliver tens of thousands of low-latency, random I/O operations per second (IOPS) to applications. For more information, including the technology used, see the [Amazon EC2 Instance Type Details](#) page.

D2 instances

These instances are well suited for the following:

- Massive parallel processing (MPP) data warehouse
- MapReduce and Hadoop distributed computing
- Log or data processing applications

D3 and D3en instances

These instances offer scale out of instance storage and are well suited for the following:

- Distributed file systems for Hadoop workloads
- File storage workloads such as GPFS and BeeFS
- Large data lakes for HPC workloads

H1 instances

These instances are well suited for the following:

- Data-intensive workloads such as MapReduce and distributed file systems
- Applications requiring sequential access to large amounts of data on direct-attached instance storage
- Applications that require high-throughput access to large quantities of data

I3 and I3en instances

These instances are well suited for the following:

- High frequency online transaction processing (OLTP) systems
- Relational databases
- NoSQL databases
- Cache for in-memory databases (for example, Redis)
- Data warehousing applications
- Distributed file systems

Bare metal instances provide your applications with direct access to physical resources of the host server, such as processors and memory.

For more information, see [Amazon EC2 I3 Instances](#).

I4i instances

These instances are well suited for I/O intensive workloads that require small to medium sized data sets on local storage, such as transactional databases and NoSQL databases.

For more information, see [Amazon EC2 I4i Instances](#).

Hardware specifications

The following is a summary of the hardware specifications for storage optimized instances. A virtual central processing unit (vCPU) represents a portion of the physical CPU assigned to a virtual machine (VM). For x86 instances, there are two vCPUs per core. For Graviton instances, there is one vCPU per core.

Instance type	Default vCPUs	Memory (GiB)
d2.xlarge	4	30.50
d2.2xlarge	8	61.00
d2.4xlarge	16	122.00
d2.8xlarge	36	244.00
d3.xlarge	4	32.00
d3.2xlarge	8	64.00
d3.4xlarge	16	128.00
d3.8xlarge	32	256.00
d3en.xlarge	4	16.00
d3en.2xlarge	8	32.00
d3en.4xlarge	16	64.00
d3en.6xlarge	24	96.00
d3en.8xlarge	32	128.00
d3en.12xlarge	48	192.00
h1.2xlarge	8	32.00
h1.4xlarge	16	64.00

Instance type	Default vCPUs	Memory (GiB)
h1.8xlarge	32	128.00
h1.16xlarge	64	256.00
i2.xlarge	4	30.50
i2.2xlarge	8	61.00
i2.4xlarge	16	122.00
i2.8xlarge	32	244.00
i3.large	2	15.25
i3.xlarge	4	30.50
i3.2xlarge	8	61.00
i3.4xlarge	16	122.00
i3.8xlarge	32	244.00
i3.16xlarge	64	488.00
i3.metal	72	512.00
i3en.large	2	16.00
i3en.xlarge	4	32.00
i3en.2xlarge	8	64.00
i3en.3xlarge	12	96.00
i3en.6xlarge	24	192.00
i3en.12xlarge	48	384.00
i3en.24xlarge	96	768.00
i3en.metal	96	768.00
i4i.large	2	16.00
i4i.xlarge	4	32.00
i4i.2xlarge	8	64.00
i4i.4xlarge	16	128.00
i4i.8xlarge	32	256.00
i4i.16xlarge	64	512.00
i4i.32xlarge	128	1024.00
i4i.metal	128	1024.00

The storage optimized instances use the following processors.

Intel processors

- **Intel Xeon Scalable processors (Haswell E5-2676 v3):** D2
- **Intel Xeon Scalable processors (Broadwell E5-2686 v4):** H1, I3
- **Intel Xeon Scalable processors (Skylake 8175M or Cascade Lake 8259CL):** I3en
- **2nd generation Intel Xeon Scalable processors (Cascade Lake 8259CL):** D3, D3en
- **3rd generation Intel Xeon Scalable processors (Ice Lake 8375C):** I4i

For more information, see [Amazon EC2 Instance Types](#).

Instance performance

For instances with NVMe instance store volumes, be sure to use the AWS NVMe driver. For more information, see [AWS NVMe drivers for Windows instances \(p. 799\)](#).

EBS-optimized instances enable you to get consistently high performance for your EBS volumes by eliminating contention between Amazon EBS I/O and other network traffic from your instance. Some storage optimized instances are EBS-optimized by default at no additional cost. For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).

Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see [Enhanced networking on Windows \(p. 1326\)](#).

The following is a summary of network performance for storage optimized instances that support enhanced networking.

Note

Instance types indicated with a † have a baseline bandwidth and can use a network I/O credit mechanism to burst beyond their baseline bandwidth on a best effort basis. For more information, see [instance network bandwidth \(p. 1324\)](#).

Instance type	Network performance	Enhanced networking features
d2.xlarge	Moderate	Not supported
d2.2xlarge	High	Not supported
d2.4xlarge	High	Not supported
d2.8xlarge	10 Gigabit	Not supported
d3.xlarge †	Up to 15 Gigabit	ENI
d3.2xlarge †	Up to 15 Gigabit	ENI
d3.4xlarge †	Up to 15 Gigabit	ENI
d3.8xlarge	25 Gigabit	ENI
d3en.xlarge †	Up to 25 Gigabit	ENI
d3en.2xlarge †	Up to 25 Gigabit	ENI
d3en.4xlarge	25 Gigabit	ENI

Instance type	Network performance	Enhanced networking features
d3en.6xlarge	40 Gigabit	ENI
d3en.8xlarge	50 Gigabit	ENI
d3en.12xlarge	75 Gigabit	ENI
h1.2xlarge †	Up to 10 Gigabit	ENI
h1.4xlarge †	Up to 10 Gigabit	ENI
h1.8xlarge	10 Gigabit	ENI
h1.16xlarge	25 Gigabit	ENI
i2.xlarge	Moderate	Not supported
i2.2xlarge	High	Not supported
i2.4xlarge	High	Not supported
i2.8xlarge	10 Gigabit	Not supported
i3.large †	Up to 10 Gigabit	ENI
i3.xlarge †	Up to 10 Gigabit	ENI
i3.2xlarge †	Up to 10 Gigabit	ENI
i3.4xlarge †	Up to 10 Gigabit	ENI
i3.8xlarge	10 Gigabit	ENI
i3.16xlarge	25 Gigabit	ENI
i3.metal	25 Gigabit	ENI
i3en.large †	Up to 25 Gigabit	ENI
i3en.xlarge †	Up to 25 Gigabit	ENI
i3en.2xlarge †	Up to 25 Gigabit	ENI
i3en.3xlarge †	Up to 25 Gigabit	ENI
i3en.6xlarge	25 Gigabit	ENI
i3en.12xlarge	50 Gigabit	ENI EFA
i3en.24xlarge	100 Gigabit	ENI EFA
i3en.metal	100 Gigabit	ENI EFA
i4i.large †	Up to 10 Gigabit	ENI
i4i.xlarge †	Up to 10 Gigabit	ENI
i4i.2xlarge †	Up to 12 Gigabit	ENI
i4i.4xlarge †	Up to 25 Gigabit	ENI
i4i.8xlarge	18.75 Gigabit	ENI

Instance type	Network performance	Enhanced networking features
i4i.16xlarge	37.5 Gigabit	ENI
i4i.32xlarge	75 Gigabit	ENI EFA
i4i.metal	75 Gigabit	ENI EFA

The following table shows the baseline and burst bandwidth for instance types that use the network I/O credit mechanism to burst beyond their baseline bandwidth.

Instance type	Baseline bandwidth (Gbps)	Burst bandwidth (Gbps)
d3.xlarge	3.0	15.0
d3.2xlarge	6.0	15.0
d3.4xlarge	12.5	15.0
d3en.xlarge	6.0	25.0
d3en.2xlarge	12.5	25.0
h1.2xlarge	2.5	10.0
h1.4xlarge	5.0	10.0
i3.large	0.75	10.0
i3.xlarge	1.25	10.0
i3.2xlarge	2.5	10.0
i3.4xlarge	5.0	10.0
i3en.large	2.1	25.0
i3en.xlarge	4.2	25.0
i3en.2xlarge	8.4	25.0
i3en.3xlarge	12.5	25.0
i4i.large	0.781	10.0
i4i.xlarge	1.875	10.0
i4i.2xlarge	4.687	12.0
i4i.4xlarge	9.375	25.0

Amazon EBS I/O performance

Amazon EBS optimized instances use an optimized configuration stack and provide additional, dedicated capacity for Amazon EBS I/O. This optimization provides the best performance for your Amazon EBS volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).

SSD-based instance store volume I/O performance

The primary data storage for D2, D3, and D3en instances is HDD instance store volumes. The primary data storage for I3 and I3en instances is non-volatile memory express (NVMe) SSD instance store volumes.

Instance store volumes persist only for the life of the instance. When you stop, hibernate, or terminate an instance, the applications and data in its instance store volumes are erased. We recommend that you regularly back up or replicate important data in your instance store volumes. For more information, see [Amazon EC2 instance store \(p. 1996\)](#) and [SSD instance store volumes \(p. 2012\)](#).

If you use all the SSD-based instance store volumes available to your instance, you can get up to the IOPS (4,096 byte block size) performance listed in the following table (at queue depth saturation). Otherwise, you get lower IOPS performance.

Instance Size	100% Random Read IOPS	Write IOPS
i3.large	100,125	35,000
i3.xlarge	206,250	70,000
i3.2xlarge	412,500	180,000
i3.4xlarge	825,000	360,000
i3.8xlarge	1,650,000	720,000
i3.16xlarge	3,300,000	1,400,000
i3.metal	3,300,000	1,400,000
i3en.large	42,500	32,500
i3en.xlarge	85,000	65,000
i3en.2xlarge	170,000	130,000
i3en.3xlarge	250,000	200,000
i3en.6xlarge	500,000	400,000
i3en.12xlarge	1,000,000	800,000
i3en.24xlarge	2,000,000	1,600,000
i3en.metal	2,000,000	1,600,000
i4i.large	50,000	27,500
i4i.xlarge	100,000	55,000
i4i.2xlarge	200,000	110,000
i4i.4xlarge	400,000	220,000
i4i.8xlarge	800,000	440,000
i4i.16xlarge	1,600,000	880,000
i4i.32xlarge	3,200,000	1,760,000

Instance Size	100% Random Read IOPS	Write IOPS
i4i.metal	3,200,000	1,760,000

As you fill your SSD-based instance store volumes, the I/O performance that you get decreases. This is due to the extra work that the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called *over-provisioning*. The SSD-based instance store volumes provided to an instance don't have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see [Instance store volume TRIM support \(p. 2013\)](#).

For a comparison of the volume size across all instance types that support instance store volumes, see the [Available instance store volumes \(p. 1999\)](#) table.

Release notes

- Instances built on the [Nitro System \(p. 218\)](#) have the following requirements:
 - [NVMe drivers \(p. 1939\)](#) must be installed
 - [Elastic Network Adapter \(ENA\) drivers \(p. 1327\)](#) must be installed

The current [AWS Windows AMIs \(p. 41\)](#) meet these requirements.

- Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.
- To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support.
- Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.
- The d3.8xlarge and d3en.12xlarge instances support a maximum of three attachments, including the root volume. If you exceed the attachment limit when you add a network interface or EBS volume, this causes attachment issues on your instance.
- There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see [How many instances can I run in Amazon EC2?](#) in the Amazon EC2 FAQ.

Windows accelerated computing instances

Accelerated computing instances use hardware accelerators, or co-processors, to perform some functions, such as floating point number calculations, graphics processing, or data pattern matching, more efficiently than is possible in software running on CPUs. These instances enable more parallelism for higher throughput on compute-intensive workloads.

If you require high processing capability, you'll benefit from using accelerated computing instances, which provide access to hardware-based compute accelerators such as Graphics Processing Units (GPUs).

GPU instances

GPU-based instances provide access to NVIDIA GPUs with thousands of compute cores. You can use these instances to accelerate scientific, engineering, and rendering applications by leveraging the CUDA or Open Computing Language (OpenCL) parallel computing frameworks. You can also use them for graphics applications, including game streaming, 3-D application streaming, and other graphics workloads.

If your application needs a small amount of additional graphics acceleration, but is better suited for an instance type with different compute, memory, or storage specifications, use an Elastic Graphics accelerator instead. For more information, see [Amazon Elastic Graphics \(p. 1135\)](#).

G5 instances

G5 instances use NVIDIA A10G GPUs and provide high performance for graphics-intensive applications such as remote workstations, video rendering, and cloud gaming, and deep learning models for applications such as natural language processing, computer vision, and recommendation engines. These instances feature up to 8 NVIDIA A10G GPUs, second generation AMD EPYC processors, up to 100 Gbps of network bandwidth, and up to 7.6 TB of local NVMe SSD storage.

For more information, see [Amazon EC2 G5 Instances](#).

G4ad and G4dn instances

G4ad instances use AMD Radeon Pro V520 GPUs and 2nd generation AMD EPYC processors, and are well-suited for graphics applications such as remote graphics workstations, game streaming, and rendering that leverage industry-standard APIs such as OpenGL, DirectX, and Vulkan. They provide up to 4 AMD Radeon Pro V520 GPUs, 64 vCPUs, 25 Gbps networking, and 2.4 TB local NVMe-based SSD storage.

G4dn instances use NVIDIA Tesla GPUs and provide a cost-effective, high-performance platform for general purpose GPU computing using the CUDA or machine learning frameworks along with graphics applications using DirectX or OpenGL. These instances provide high-bandwidth networking, powerful half and single-precision floating-point capabilities, along with INT8 and INT4 precisions. Each GPU has 16 GiB of GDDR6 memory, making G4dn instances well-suited for machine learning inference, video transcoding, and graphics applications like remote graphics workstations and game streaming in the cloud.

For more information, see [Amazon EC2 G4 Instances](#).

G4dn instances support NVIDIA GRID Virtual Workstation. For more information, see [NVIDIA Marketplace offerings](#).

G3 instances

These instances use NVIDIA Tesla M60 GPUs and provide a cost-effective, high-performance platform for graphics applications using DirectX or OpenGL. G3 instances also provide NVIDIA GRID Virtual Workstation features, such as support for four monitors with resolutions up to 4096x2160, and NVIDIA GRID Virtual Applications. G3 instances are well-suited for applications such as 3D visualizations, graphics-intensive remote workstations, 3D rendering, video encoding, virtual reality, and other server-side graphics workloads requiring massively parallel processing power.

For more information, see [Amazon EC2 G3 Instances](#).

G3 instances support NVIDIA GRID Virtual Workstation and NVIDIA GRID Virtual Applications. To activate either of these features, see [Activate NVIDIA GRID Virtual Applications \(p. 338\)](#).

G2 instances

These instances use NVIDIA GRID K520 GPUs and provide a cost-effective, high-performance platform for graphics applications using DirectX or OpenGL. NVIDIA GRID GPUs also support NVIDIA's fast capture and encode API operations. Example applications include video creation services, 3D visualizations, streaming graphics-intensive applications, and other server-side graphics workloads.

P5 instances

P5 instances provide 8 NVIDIA H100 GPUs with 640 GB of high-bandwidth GPU memory. They feature 3rd generation AMD EPYC processors and provide 2 TB of system memory, 30 TB of local NVMe instance storage, 3,200 Gbps aggregated network bandwidth, and GPUDirect RDMA support. P5 instances also support Amazon EC2 UltraCluster technology, which provides lower latency and improved network performance using EFA. For machine learning and HPC workloads, P5 instances provide up to 6 times higher performance than previous generation GPU instances.

P5 instances can accelerate a broad range of GPU-enabled workloads, and are well-suited to large-scale distributed machine learning and high-performance computing applications.

For more information, see [Amazon EC2 P5 instances](#).

P4de instances offer NVIDIA 80GB-A100s GPUs

P3 instances

These instances use NVIDIA Tesla V100 GPUs and are designed for general purpose GPU computing using the CUDA or OpenCL programming models or through a machine learning framework. P3 instances provide high-bandwidth networking, powerful half, single, and double-precision floating-point capabilities, and up to 32 GiB of memory per GPU, which makes them ideal for deep learning, computational fluid dynamics, computational finance, seismic analysis, molecular modeling, genomics, rendering, and other server-side GPU compute workloads. Tesla V100 GPUs do not support graphics mode.

For more information, see [Amazon EC2 P3 Instances](#).

P3 instances support NVIDIA NVLink peer to peer transfers. For more information, see [NVIDIA NVLink](#).

P2 instances

P2 instances use NVIDIA Tesla K80 GPUs and are designed for general purpose GPU computing using the CUDA or OpenCL programming models. P2 instances provide high-bandwidth networking, powerful single and double precision floating-point capabilities, and 12 GiB of memory per GPU, which makes them ideal for deep learning, graph databases, high-performance databases, computational fluid dynamics, computational finance, seismic analysis, molecular modeling, genomics, rendering, and other server-side GPU compute workloads.

P2 instances support NVIDIA GPUDirect peer to peer transfers. For more information, see [NVIDIA GPUDirect](#).

Instances with AWS Trainium

Amazon EC2 Trn1 and Trn1n instances, powered by [AWS Trainium](#), are purpose built for high-performance, cost-effective deep learning training. You can use Trn1 and Trn1n instances to train natural language processing, computer vision, and recommender models used across a broad set of applications, such as speech recognition, recommendation, fraud detection, and image and video classification. Use your existing workflows in popular ML frameworks, such as PyTorch and TensorFlow. [AWS Neuron SDK](#) integrates seamlessly with these frameworks so that you can get started with only a few lines of code changes.

For more information, see [Amazon EC2 Trn1 instances](#).

Hardware specifications

The following is a summary of the hardware specifications for accelerated computing instances. A virtual central processing unit (vCPU) represents a portion of the physical CPU assigned to a virtual machine (VM). For x86 instances, there are two vCPUs per core. For Graviton instances, there is one vCPU per core.

Instance type	Default vCPUs	Memory (GiB)	Accelerators
f1.2xlarge	8	122.00	1 FPGAs
f1.4xlarge	16	244.00	2 FPGAs
f1.16xlarge	64	976.00	8 FPGAs
g2.2xlarge	8	15.00	1 GPUs
g2.8xlarge	32	60.00	4 GPUs
g3.4xlarge	16	122.00	1 GPUs
g3.8xlarge	32	244.00	2 GPUs
g3.16xlarge	64	488.00	4 GPUs
g4ad.xlarge	4	16.00	1 GPUs
g4ad.2xlarge	8	32.00	1 GPUs
g4ad.4xlarge	16	64.00	1 GPUs
g4ad.8xlarge	32	128.00	2 GPUs

Instance type	Default vCPUs	Memory (GiB)	Accelerators
g4ad.16xlarge	64	256.00	4 GPUs
g4dn.xlarge	4	16.00	1 GPUs
g4dn.2xlarge	8	32.00	1 GPUs
g4dn.4xlarge	16	64.00	1 GPUs
g4dn.8xlarge	32	128.00	1 GPUs
g4dn.12xlarge	48	192.00	4 GPUs
g4dn.16xlarge	64	256.00	1 GPUs
g4dn.metal	96	384.00	8 GPUs
g5.xlarge	4	16.00	1 GPUs
g5.2xlarge	8	32.00	1 GPUs
g5.4xlarge	16	64.00	1 GPUs
g5.8xlarge	32	128.00	1 GPUs
g5.12xlarge	48	192.00	4 GPUs
g5.16xlarge	64	256.00	1 GPUs
g5.24xlarge	96	384.00	4 GPUs
g5.48xlarge	192	768.00	8 GPUs
p2.xlarge	4	61.00	1 GPUs
p2.8xlarge	32	488.00	8 GPUs
p2.16xlarge	64	732.00	16 GPUs
p3.2xlarge	8	61.00	1 GPUs
p3.8xlarge	32	244.00	4 GPUs
p3.16xlarge	64	488.00	8 GPUs
p3dn.24xlarge	96	768.00	8 GPUs

Note

trn1n.32xlarge instances feature 16 Trainium Accelerators.

Trn1 instances feature the following number of Trainium Accelerators.

- **trn1.2xlarge** — 1
- **trn1.32xlarge** — 16

VT1 instances feature the following number of U30 Accelerators.

- **vt1.3xlarge** — 1
- **vt1.6xlarge** — 2
- **vt1.24xlarge** — 16

The accelerated computing instances use the following processors.

AMD processors

- **2nd generation AMD EPYC processors (AMD EPYC 7R32):** G4ad, G5
- **3rd generation AMD EPYC processors (AMD EPYC 7R13):** P5

Intel processors

- **Intel Xeon Scalable processors (Broadwell E5-2686 v4):** G3, P2, P3
- **Intel Xeon Scalable processors (Skylake 8175):** P3dn
- **2nd generation Intel Xeon Scalable processors (Cascade Lake P-8259CL):** VT1
- **2nd generation Intel Xeon Scalable processors (Cascade Lake P-8259L):** G4dn

For more information, see [Amazon EC2 Instance Types](#).

Instance performance

EBS-optimized instances enable you to get consistently high performance for your EBS volumes by eliminating contention between Amazon EBS I/O and other network traffic from your instance. Some accelerated computing instances are EBS-optimized by default at no additional cost. For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).

Network performance

You can enable enhanced networking on supported instance types to provide lower latencies, lower network jitter, and higher packet-per-second (PPS) performance. Most applications do not consistently need a high level of network performance, but can benefit from access to increased bandwidth when they send or receive data. For more information, see [Enhanced networking on Windows \(p. 1326\)](#).

The following is a summary of network performance for accelerated computing instances that support enhanced networking.

Note

Instance types indicated with a † have a baseline bandwidth and can use a network I/O credit mechanism to burst beyond their baseline bandwidth on a best effort basis. For more information, see [instance network bandwidth \(p. 1324\)](#).

Instance type	Network performance	Enhanced networking features
f1.2xlarge †	Up to 10 Gigabit	Not supported
f1.4xlarge †	Up to 10 Gigabit	Not supported
f1.16xlarge	25 Gigabit	Not supported
g2.2xlarge	Moderate	Not supported
g2.8xlarge	High	Not supported
g3.4xlarge †	Up to 10 Gigabit	ENA
g3.8xlarge	10 Gigabit	ENA
g3.16xlarge	25 Gigabit	ENA
g4ad.xlarge †	Up to 10 Gigabit	ENA

Instance type	Network performance	Enhanced networking features
g4ad.2xlarge †	Up to 10 Gigabit	ENI
g4ad.4xlarge †	Up to 10 Gigabit	ENI
g4ad.8xlarge	15 Gigabit	ENI
g4ad.16xlarge	25 Gigabit	ENI
g4dn.xlarge †	Up to 25 Gigabit	ENI
g4dn.2xlarge †	Up to 25 Gigabit	ENI
g4dn.4xlarge †	Up to 25 Gigabit	ENI
g4dn.8xlarge	50 Gigabit	ENI EFA
g4dn.12xlarge	50 Gigabit	ENI EFA
g4dn.16xlarge	50 Gigabit	ENI EFA
g4dn.metal	100 Gigabit	ENI EFA
g5.xlarge †	Up to 10 Gigabit	ENI
g5.2xlarge †	Up to 10 Gigabit	ENI
g5.4xlarge †	Up to 25 Gigabit	ENI
g5.8xlarge	25 Gigabit	ENI EFA
g5.12xlarge	40 Gigabit	ENI EFA
g5.16xlarge	25 Gigabit	ENI EFA
g5.24xlarge	50 Gigabit	ENI EFA
g5.48xlarge	100 Gigabit	ENI EFA
p2.xlarge	High	ENI
p2.8xlarge	10 Gigabit	ENI
p2.16xlarge	25 Gigabit	ENI
p3.2xlarge †	Up to 10 Gigabit	ENI
p3.8xlarge	10 Gigabit	ENI
p3.16xlarge	25 Gigabit	ENI
p3dn.24xlarge	100 Gigabit	ENI EFA

The following table shows the baseline and burst bandwidth for instance types that use the network I/O credit mechanism to burst beyond their baseline bandwidth.

Instance type	Baseline bandwidth (Gbps)	Burst bandwidth (Gbps)
g3.4xlarge	5	10

Instance type	Baseline bandwidth (Gbps)	Burst bandwidth (Gbps)
g4ad.xlarge	2.0	10.0
g4ad.2xlarge	4.167	10.0
g4ad.4xlarge	8.333	10.0
g4dn.xlarge	5.0	25.0
g4dn.2xlarge	10.0	25.0
g4dn.4xlarge	20.0	25.0
g5.xlarge	2.5	10.0
g5.2xlarge	5.0	10.0
g5.4xlarge	10.0	25.0

Amazon EBS I/O performance

Amazon EBS optimized instances use an optimized configuration stack and provide additional, dedicated capacity for Amazon EBS I/O. This optimization provides the best performance for your Amazon EBS volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).

SSD-based instance store volume I/O performance

If you use all the SSD-based instance store volumes available to your instance, you can get up to the IOPS (4,096 byte block size) performance listed in the following table (at queue depth saturation). Otherwise, you get lower IOPS performance.

Instance Size	100% Random Read IOPS	Write IOPS
g4ad.xlarge	10417	8333
g4ad.2xlarge	20833	16667
g4ad.4xlarge	41667	33333
g4ad.8xlarge	83333	66667
g4ad.16xlarge	166666	133332
g4dn.xlarge	42500	32500
g4dn.2xlarge	42500	32500
g4dn.4xlarge	85000	65000
g4dn.8xlarge	250000	200000
g4dn.12xlarge	250000	200000
g4dn.16xlarge	250000	200000
g4dn.metal	500000	400000

Instance Size	100% Random Read IOPS	Write IOPS
g5.xlarge	40625	20313
g5.2xlarge	40625	20313
g5.4xlarge	125000	62500
g5.8xlarge	250000	125000
g5.12xlarge	312500	156250
g5.16xlarge	250000	125000
g5.24xlarge	312500	156250
g5.48xlarge	625000	312500
p3dn.24xlarge	700000	340000

As you fill the SSD-based instance store volumes for your instance, the number of write IOPS that you can achieve decreases. This is due to the extra work the SSD controller must do to find available space, rewrite existing data, and erase unused space so that it can be rewritten. This process of garbage collection results in internal write amplification to the SSD, expressed as the ratio of SSD write operations to user write operations. This decrease in performance is even larger if the write operations are not in multiples of 4,096 bytes or not aligned to a 4,096-byte boundary. If you write a smaller amount of bytes or bytes that are not aligned, the SSD controller must read the surrounding data and store the result in a new location. This pattern results in significantly increased write amplification, increased latency, and dramatically reduced I/O performance.

SSD controllers can use several strategies to reduce the impact of write amplification. One such strategy is to reserve space in the SSD instance storage so that the controller can more efficiently manage the space available for write operations. This is called *over-provisioning*. The SSD-based instance store volumes provided to an instance don't have any space reserved for over-provisioning. To reduce write amplification, we recommend that you leave 10% of the volume unpartitioned so that the SSD controller can use it for over-provisioning. This decreases the storage that you can use, but increases performance even if the disk is close to full capacity.

For instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller whenever you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. For more information, see [Instance store volume TRIM support \(p. 2013\)](#).

Release notes

- For the best performance with P5 instances, we recommend that you do the following:
 - Use an AMI with Linux kernel version 5.10 or later.
 - You must launch the instance using an HVM AMI.
 - Instances built on the [Nitro System \(p. 218\)](#) have the following requirements:
 - [NVMe drivers \(p. 1939\)](#) must be installed
 - [Elastic Network Adapter \(ENA\) drivers \(p. 1327\)](#) must be installed

The current [AWS Windows AMIs \(p. 41\)](#) meet these requirements.

- GPU-based instances can't access the GPU unless the NVIDIA drivers are installed. For more information, see [Install NVIDIA drivers on Windows instances \(p. 329\)](#).

- Launching a bare metal instance boots the underlying server, which includes verifying all hardware and firmware components. This means that it can take 20 minutes from the time the instance enters the running state until it becomes available over the network.
- To attach or detach EBS volumes or secondary network interfaces from a bare metal instance requires PCIe native hotplug support.
- Bare metal instances use a PCI-based serial device rather than an I/O port-based serial device. The upstream Linux kernel and the latest Amazon Linux AMIs support this device. Bare metal instances also provide an ACPI SPCR table to enable the system to automatically use the PCI-based serial device. The latest Windows AMIs automatically use the PCI-based serial device.
- There is a limit of 100 AFIs per Region.
- There is a limit on the total number of instances that you can launch in a Region, and there are additional limits on some instance types. For more information, see [How many instances can I run in Amazon EC2?](#) in the Amazon EC2 FAQ.
- If you launch a multi-GPU instance with a Windows AMI that was created on a single-GPU instance, Windows does not automatically install the NVIDIA driver for all GPUs. You must authorize the driver installation for the new GPU hardware. You can correct this manually in the Device Manager by opening the **Other** device category (the inactive GPUs do not appear under **Display Adapters**). For each inactive GPU, open the context (right-click) menu, choose **Update Driver Software**, and then choose the default **Automatic Update** option.
- When using Microsoft Remote Desktop Protocol (RDP), GPUs that use the WDDM driver model are replaced with a non-accelerated Remote Desktop display driver. We recommend that you use a different remote access tool to access your GPU, such as [Teradici Cloud Access Software](#), [NICE Desktop Cloud Visualization \(DCV\)](#), or VNC. You can also use one of the GPU AMIs from the AWS Marketplace because they provide remote access tools that support 3D acceleration.

Install NVIDIA drivers on Windows instances

An instance with an attached NVIDIA GPU, such as a P3 or G4dn instance, must have the appropriate NVIDIA driver installed. Depending on the instance type, you can either download a public NVIDIA driver, download a driver from Amazon S3 that is available only to AWS customers, or use an AMI with the driver pre-installed.

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](#).

To install AMD drivers on a Linux instance with an attached AMD GPU, such as a G4ad instance, see [Install AMD drivers \(p. 337\)](#) instead. To install NVIDIA drivers on a Linux instance, see [Install NVIDIA drivers on a Linux instance](#).

Contents

- [Types of NVIDIA drivers \(p. 330\)](#)
- [Available drivers by instance type \(p. 330\)](#)
- [Installation options \(p. 331\)](#)
 - [Option 1: AMIs with the NVIDIA drivers installed \(p. 331\)](#)
 - [Option 2: Public NVIDIA drivers \(p. 331\)](#)
 - [Option 3: GRID drivers \(G5, G4dn, and G3 instances\) \(p. 332\)](#)
 - [Option 4: NVIDIA gaming drivers \(G5 and G4dn instances\) \(p. 334\)](#)
- [Install an additional version of CUDA \(p. 336\)](#)

Types of NVIDIA drivers

The following are the main types of NVIDIA drivers that can be used with GPU-based instances.

Tesla drivers

These drivers are intended primarily for compute workloads, which use GPUs for computational tasks such as parallelized floating-point calculations for machine learning and fast Fourier transforms for high performance computing applications.

GRID drivers

These drivers are certified to provide optimal performance for professional visualization applications that render content such as 3D models or high-resolution videos. You can configure GRID drivers to support two modes. Quadro Virtual Workstations provide access to four 4K displays per GPU. GRID vApps provide RDSH App hosting capabilities.

Gaming drivers

These drivers contain optimizations for gaming and are updated frequently to provide performance enhancements. They support a single 4K display per GPU.

Configured mode

On Windows, the Tesla drivers are configured to run in Tesla Compute Cluster (TCC) mode. The GRID and gaming drivers are configured to run in Windows Display Driver Model (WDDM) mode. In TCC mode, the card is dedicated to compute workloads. In WDDM mode, the card supports both compute and graphics workloads.

NVIDIA control panel

The NVIDIA control panel is supported with GRID and Gaming drivers. It is not supported with Tesla drivers.

Supported APIs for Tesla drivers

- OpenCL
- NVIDIA CUDA and related libraries (for example, cuDNN, TensorRT, nvJPEG, and cuBLAS)
- NVENC for video encoding and NVDEC for video decoding

Supported APIs for GRID and gaming drivers

- DirectX, Direct2D, DirectX Video Acceleration, DirectX Raytracing
- OpenCL, OpenGL, and Vulkan
- NVIDIA CUDA and related libraries (for example, cuDNN, TensorRT, nvJPEG, and cuBLAS)
- NVENC for video encoding and NVDEC for video decoding

Available drivers by instance type

The following table summarizes the supported NVIDIA drivers for each GPU instance type.

Instance type	Tesla driver	GRID driver	Gaming driver
G2	Yes	No	No
G3	Yes	Yes	No
G4dn	Yes	Yes	Yes

Instance type	Tesla driver	GRID driver	Gaming driver
G5	Yes	Yes	Yes
P2	Yes	No	No
P3	Yes	Yes ²	No

¹ This Tesla driver also supports optimized graphics applications specific to the ARM64 platform

Installation options

Use one of the following options to get the NVIDIA drivers required for your GPU instance.

Options

- [Option 1: AMIs with the NVIDIA drivers installed \(p. 331\)](#)
- [Option 2: Public NVIDIA drivers \(p. 331\)](#)
- [Option 3: GRID drivers \(G5, G4dn, and G3 instances\) \(p. 332\)](#)
- [Option 4: NVIDIA gaming drivers \(G5 and G4dn instances\) \(p. 334\)](#)

Option 1: AMIs with the NVIDIA drivers installed

AWS and NVIDIA offer different Amazon Machine Images (AMI) that come with the NVIDIA drivers installed.

- [Marketplace offerings with the Tesla driver](#)
- [Marketplace offerings with the GRID driver](#)
- [Marketplace offerings with the Gaming driver](#)

If you create a custom Windows AMI using one of the AWS Marketplace offerings, the AMI must be a standardized image created [using Sysprep \(p. 154\)](#) to ensure that the GRID driver works.

Option 2: Public NVIDIA drivers

The options offered by AWS come with the necessary license for the driver. Alternatively, you can install the public drivers and bring your own license. To install a public driver, download it from the NVIDIA site as described here.

Alternatively, you can use the options offered by AWS instead of the public drivers. To use a GRID driver on a P3 instance, use the AWS Marketplace AMIs as described in [Option 1 \(p. 331\)](#). To use a GRID driver on a G5, G4dn, or G3 instance, use the AWS Marketplace AMIs, as described in Option 1 or install the NVIDIA drivers provided by AWS as described in [Option 3 \(p. 332\)](#).

To download a public NVIDIA driver

Log on to your Windows instance and download the 64-bit NVIDIA driver appropriate for the instance type from <http://www.nvidia.com/Download/Find.aspx>. For **Product Type**, **Product Series**, and **Product**, use the options in the following table.

Instance	Product Type	Product Series	Product
G2	GRID	GRID Series	GRID K520
G3	Tesla	M-Class	M60
G4dn	Tesla	T-Series	T4

Instance	Product Type	Product Series	Product
G5 ¹	Tesla	A-Series	A10
P2	Tesla	K-Series	K80
P3	Tesla	V-Series	V100
P5 ³	Tesla	H-Series	H100

¹ G5 instances require driver version 470.00 or later

² G5g instances require driver version 470.82.01 or later. The operating system is Linux aarch64

³ P5 instances require driver version 530 or later.

To install the NVIDIA driver on Windows

1. Open the folder where you downloaded the driver and launch the installation file. Follow the instructions to install the driver and reboot your instance as required.
2. Disable the display adapter named **Microsoft Basic Display Adapter** that is marked with a warning icon using Device Manager. Install these Windows features: **Media Foundation** and **Quality Windows Audio Video Experience**.

Important

Don't disable the display adapter named **Microsoft Remote Display Adapter**. If **Microsoft Remote Display Adapter** is disabled your connection might be interrupted and attempts to connect to the instance after it has rebooted might fail.

3. Check Device Manager to verify that the GPU is working correctly.
4. To achieve the best performance from your GPU, complete the optimization steps in [Optimize GPU settings \(p. 339\)](#).

Option 3: GRID drivers (G5, G4dn, and G3 instances)

These downloads are available to AWS customers only. By downloading, you agree to use the downloaded software only to develop AMIs for use with the NVIDIA A10G, NVIDIA Tesla T4, or NVIDIA Tesla M60 hardware. Upon installation of the software, you are bound by the terms of the [NVIDIA GRID Cloud End User License Agreement](#).

Considerations

- If you launch your Windows instance using a custom Windows AMI, the AMI must be a standardized image created [using Sysprep \(p. 154\)](#) to ensure that the GRID driver works.
- G3 instances require AWS provided DNS resolution for GRID licensing to work.
- [IMDSv2 \(p. 863\)](#) is only supported with NVIDIA driver version 14.0 or greater.

To install the NVIDIA GRID driver on your Windows instance

1. Connect to your Windows instance and open a PowerShell window.
2. Configure default credentials for the AWS Tools for Windows PowerShell on your Windows instance. For more information, see [Getting Started with the AWS Tools for Windows PowerShell](#) in the [AWS Tools for Windows PowerShell User Guide](#).

Important

Your user or role must have the permissions granted that contains the **AmazonS3ReadOnlyAccess** policy. For more information, see [AWS managed policy: AmazonS3ReadOnlyAccess](#) in the *Amazon Simple Storage Service User Guide*.

3. Download the drivers and the [NVIDIA GRID Cloud End User License Agreement](#) from Amazon S3 to your desktop using the following PowerShell commands.

```
$Bucket = "ec2-windows-nvidia-drivers"
$keyPrefix = "latest"
$localPath = "$home\Desktop\NVIDIA"
$objects = Get-S3Object -BucketName $Bucket -KeyPrefix $keyPrefix -Region us-east-1
foreach ($object in $objects) {
    $localFileName = $object.Key
    if ($localFileName -ne '' -and $object.Size -ne 0) {
        $localFilePath = Join-Path $localPath $localFileName
        Copy-S3Object -BucketName $Bucket -Key $object.Key -LocalFile $localFilePath -Region us-east-1
    }
}
```

Multiple versions of the NVIDIA GRID driver are stored in this bucket. You can download all of the available Windows versions in the bucket by removing the `-KeyPrefix $keyPrefix` option. For information about the version of the NVIDIA GRID driver for your operating system, see the [NVIDIA® Virtual GPU \(vGPU\) Software Documentation](#) on the [NVIDIA website](#).

Starting with GRID version 11.0, you can use the drivers under `latest` for both G3 and G4dn instances. We will not add versions later than 11.0 to `g4/latest`, but will keep version 11.0 and the earlier versions specific to G4dn under `g4/latest`.

G5 instances require GRID 13.1 or later (or GRID 12.4 or later).

4. Navigate to the desktop and double-click the installation file to launch it (choose the driver version that corresponds to your instance OS version). Follow the instructions to install the driver and reboot your instance as required. To verify that the GPU is working properly, check Device Manager.
5. (Optional) Use the following command to disable the licensing page in the control panel to prevent users from accidentally changing the product type (NVIDIA GRID Virtual Workstation is enabled by default). For more information, see the [GRID Licensing User Guide](#).

PowerShell

Run the following PowerShell commands to create the registry value to disable the licensing page in the control panel. The AWS Tools for PowerShell in AWS Windows AMIs defaults to the 32-bit version and this command fails. Instead, use the 64-bit version of PowerShell included with the operating system.

```
New-Item -Path "HKLM:\SOFTWARE\NVIDIA Corporation\Global" -Name GridLicensing
New-ItemProperty -Path "HKLM:\SOFTWARE\NVIDIA Corporation\Global\GridLicensing" -Name "NvCplDisableManageLicensePage" -PropertyType "DWord" -Value "1"
```

Command Prompt

Run the following registry command to create the registry value to disable the licensing page in the control panel. You can run it using the Command Prompt window or a 64-bit version of PowerShell.

```
reg add "HKLM\SOFTWARE\NVIDIA Corporation\Global\GridLicensing" /v NvCplDisableManageLicensePage /t REG_DWORD /d 1
```

6. (Optional) Depending on your use case, you might complete the following optional steps. If you do not require this functionality, do not complete these steps.
 - a. To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol, [NICE DCV](#).
 - b. NVIDIA Quadro Virtual Workstation mode is enabled by default. To activate GRID Virtual Applications for RDSH Application hosting capabilities, complete the GRID Virtual Application activation steps in [Activate NVIDIA GRID Virtual Applications \(p. 338\)](#).

Option 4: NVIDIA gaming drivers (G5 and G4dn instances)

These drivers are available to AWS customers only. By downloading them, you agree to use the downloaded software only to develop AMIs for use with the NVIDIA A10G and NVIDIA Tesla T4 hardware. Upon installation of the software, you are bound by the terms of the [NVIDIA GRID Cloud End User License Agreement](#).

Prerequisites

- If you launch your Windows instance using a custom Windows AMI, the AMI must be a standardized image created [using Sysprep \(p. 154\)](#) to ensure that the gaming driver works.
- Configure default credentials for the AWS Tools for Windows PowerShell on your Windows instance. For more information, see [Getting Started with the AWS Tools for Windows PowerShell](#) in the *AWS Tools for Windows PowerShell User Guide*.
- Your users or role must have the permissions granted that contains the **AmazonS3ReadOnlyAccess** policy. For more information, see [AWS managed policy: AmazonS3ReadOnlyAccess](#) in the *Amazon Simple Storage Service User Guide*.
- G3 instances require AWS provided DNS resolution for GRID licensing to work.
- [IMDSv2 \(p. 863\)](#) is only supported with NVIDIA driver version 495.x or greater.

To install the NVIDIA gaming driver on your Windows instance

1. Connect to your Windows instance and open a PowerShell window.
2. Download and install the gaming driver using the following PowerShell commands.

```
$Bucket = "nvidia-gaming"
$keyPrefix = "windows/latest"
$localPath = "$home\Desktop\NVIDIA"
$objects = Get-S3Object -BucketName $Bucket -KeyPrefix $keyPrefix -Region us-east-1
foreach ($object in $objects) {
    $localFileName = $object.Key
    if ($localFileName -ne '' -and $object.Size -ne 0) {
        $localFilePath = Join-Path $localPath $localFileName
        Copy-S3Object -BucketName $Bucket -Key $object.Key -LocalFile $localFilePath -Region us-east-1
    }
}
```

Multiple versions of the NVIDIA GRID driver are stored in this S3 bucket. You can download all of the available versions in the bucket if you change the value of the \$keyPrefix variable from "windows/latest" to "windows".

3. Navigate to the desktop and double-click the installation file to launch it (choose the driver version that corresponds to your instance OS version). Follow the instructions to install the driver and reboot your instance as required. To verify that the GPU is working properly, check Device Manager.
4. Use one of the following methods to register the driver.

Version 527.27 or above

Create the following registry key with the 64-bit version of PowerShell, or the Command Prompt window.

key: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\nvlddmkm\Global

name: vGamingMarketplace

type: DWord

value: 2

PowerShell

Run the following PowerShell command to create this registry value. The AWS Tools for PowerShell in AWS Windows AMIs defaults to the 32-bit version and this command fails. Instead, use the 64-bit version of PowerShell included with the operating system.

```
New-ItemProperty -Path "HKLM:\SYSTEM\CurrentControlSet\Services\nvlddmkm\Global" -Name "vGamingMarketplace" -PropertyType "DWord" -Value "2"
```

Command Prompt

Run the following registry command to create this registry value. You can run it using the Command Prompt window or a 64-bit version of PowerShell.

```
reg add "HKLM\SYSTEM\CurrentControlSet\Services\nvlddmkm\Global" /v vGamingMarketplace /t REG_DWORD /d 2
```

Earlier versions

Create the following registry key with the 64-bit version of PowerShell, or the Command Prompt window.

key: HKEY_LOCAL_MACHINE\SOFTWARE\NVIDIA Corporation\Global

name: vGamingMarketplace

type: DWord

value: 2

PowerShell

Run the following PowerShell command to create this registry value. The AWS Tools for PowerShell in AWS Windows AMIs defaults to the 32-bit version and this command fails. Instead, use the 64-bit version of PowerShell included with the operating system.

```
New-ItemProperty -Path "HKLM:\SOFTWARE\NVIDIA Corporation\Global" -Name "vGamingMarketplace" -PropertyType "DWord" -Value "2"
```

Command Prompt

Run the following registry command to create this registry key with the Command Prompt window. You can also use this command in the 64-bit version of PowerShell.

```
reg add "HKLM\SOFTWARE\NVIDIA Corporation\Global" /v vGamingMarketplace /t  
REG_DWORD /d 2
```

5. Run the following command in PowerShell. This downloads the certification file, renames the file GridSwCert.txt, and moves the file to the Public Documents folder on your system drive. Typically, the folder path is C:\Users\Public\Documents.
 - For version 461.40 or later:

```
Invoke-WebRequest -Uri "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/  
GridSwCertWindows_2021_10_2.cert" -OutFile "$Env:PUBLIC\Documents\GridSwCert.txt"
```

- For version 445.87:

```
Invoke-WebRequest -Uri "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/  
GridSwCert-Windows_2020_04.cert" -OutFile "$Env:PUBLIC\Documents\GridSwCert.txt"
```

- For earlier versions:

```
Invoke-WebRequest -Uri "https://nvidia-gaming.s3.amazonaws.com/GridSwCert-Archive/  
GridSwCert-Windows_2019_09.cert" -OutFile "$Env:PUBLIC\Documents\GridSwCert.txt"
```

6. Reboot your instance.
7. Verify the NVIDIA Gaming license using the following command.

```
C:\Windows\System32\DriverStore\FileRepository\nvgrid*\nvidia-smi.exe -q
```

The output should be similar to the following.

```
vGPU Software Licensed Product  
Product Name : NVIDIA Cloud Gaming  
License Status : Licensed (Expiry: N/A)
```

8. (Optional) To help take advantage of the single display of up to 4K resolution, set up the high-performance display protocol [NICE DCV](#). If you do not require this functionality, do not complete this step.

Install an additional version of CUDA

After you install an NVIDIA graphics driver on your instance, you can install a version of CUDA other than the version that is bundled with the graphics driver. The following procedure demonstrates how to configure multiple versions of CUDA on the instance.

To install the CUDA toolkit

1. Connect to your Windows instance.
2. Open the [NVIDIA website](#) and select the version of CUDA that you need.
3. For **Installer Type**, select **exe (local)** and then choose **Download**.
4. Using your browser, run the downloaded install file. Follow the instructions to install the CUDA toolkit. You might be required to reboot the instance.

Install AMD drivers on Windows instances

An instance with an attached AMD GPU, such as a G4ad instance, must have the appropriate AMD driver installed. Depending on your requirements, you can either use an AMI with the driver preinstalled or download a driver from Amazon S3.

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](#).

To install NVIDIA drivers on an instance with an attached NVIDIA GPU, such as a G4dn instance, see [Install NVIDIA drivers \(p. 329\)](#) instead. To install AMD drivers on a Linux instance, see [Install AMD drivers on a Linux instance](#).

Contents

- [AMD Radeon Pro Software for Enterprise Driver \(p. 337\)](#)
- [AMIs with the AMD driver installed \(p. 337\)](#)
- [AMD driver download \(p. 337\)](#)

AMD Radeon Pro Software for Enterprise Driver

The AMD Radeon Pro Software for Enterprise Driver is built to deliver support for professional-grade graphics use cases. Using the driver, you can configure your instances with two 4K displays per GPU.

Supported APIs

- OpenGL, OpenCL
- Vulkan
- DirectX 9 and later
- AMD Advanced Media Framework
- Microsoft Hardware Media Foundation Transform

AMIs with the AMD driver installed

AWS offers different Amazon Machine Images (AMI) that come with the AMD drivers installed. Open [Marketplace offerings with the AMD driver](#).

AMD driver download

If you aren't using an AMI with the AMD driver installed, you can download the AMD driver and install it on your instance. The AMD driver is only supported for Windows Server 2016 and Windows Server 2019 operating systems.

These downloads are available to AWS customers only. By downloading, you agree to use the downloaded software only to develop AMIs for use with the AMD Radeon Pro V520 hardware. Upon installation of the software, you are bound by the terms of the [AMD Software End User License Agreement](#).

To install the AMD driver on your Windows instance

1. Connect to your Windows instance and open a PowerShell window.
2. Configure default credentials for the AWS Tools for Windows PowerShell on your Windows instance. For more information, see [Getting Started with the AWS Tools for Windows PowerShell](#) in the [AWS Tools for Windows PowerShell User Guide](#).

Important

Your user or role must have the permissions granted that contains the **AmazonS3ReadOnlyAccess** policy. For more information, see [AWS managed policy: AmazonS3ReadOnlyAccess](#) in the *Amazon Simple Storage Service User Guide*.

3. Download the drivers from Amazon S3 to your desktop using the following PowerShell commands.

```
$Bucket = "ec2-amd-windows-drivers"
$keyPrefix = "latest" # use "archives" for Windows Server 2016
$localPath = "$home\Desktop\AMD"
$objects = Get-S3Object -BucketName $Bucket -KeyPrefix $keyPrefix -Region us-east-1
foreach ($object in $objects) {
    $localFileName = $object.Key
    if ($localFileName -ne '' -and $object.Size -ne 0) {
        $localFilePath = Join-Path $localPath $localFileName
        Copy-S3Object -BucketName $Bucket -Key $object.Key -LocalFile $localFilePath -Region us-east-1
    }
}
```

4. Unzip the downloaded driver file and run the installer using the following PowerShell commands.

```
Expand-Archive $localFilePath -DestinationPath "$home\Desktop\AMD\$keyPrefix" -Verbose
```

Now, check the content of the new directory. The directory name can be retrieved using the `Get-ChildItem` PowerShell command.

```
Get-ChildItem "$home\Desktop\AMD\$keyPrefix"
```

The output should be similar to the following:

Directory: C:\Users\Administrator\Desktop\AMD\latest				
Mode	LastWriteTime	Length	Name	
----	-----	-----	-----	-----
d----	10/13/2021 12:52 AM		210414a-365562C-Retail_End_User.2	

Install the drivers:

```
pnputil /add-driver $home\Desktop\AMD\$keyPrefix\*.inf /install /subdirs
```

5. Follow the instructions to install the driver and reboot your instance as required.
6. To verify that the GPU is working properly, check Device Manager. You should see "AMD Radeon Pro V520 MxGPU" listed as a display adapter.
7. To help take advantage of the four displays of up to 4K resolution, set up the high-performance display protocol, [NICE DCV](#).

Activate NVIDIA GRID Virtual Applications

To activate the GRID Virtual Applications on G3, G4dn, and G5 instances (NVIDIA GRID Virtual Workstation is enabled by default), you must define the product type for the driver in the registry.

To activate GRID Virtual Applications on Windows instances

1. Run `regedit.exe` to open the registry editor.

2. Navigate to HKEY_LOCAL_MACHINE\SOFTWARE\NVIDIA Corporation\Global\GridLicensing.
3. Open the context (right-click) menu on the right pane and choose **New, DWORD**.
4. For **Name**, enter **FeatureType** and type Enter.
5. Open the context (right-click) menu on **FeatureType** and choose **Modify**.
6. For **Value data**, enter **0** for NVIDIA GRID Virtual Applications and choose **OK**.
7. Open the context (right-click) menu on the right pane and choose **New, DWORD**.
8. For **Name**, enter **IgnoreSP** and type Enter.
9. Open the context (right-click) menu on **IgnoreSP** and choose **Modify**.
10. For **Value data**, type **1** and choose **OK**.
11. Close the registry editor.

Optimize GPU settings

There are several GPU setting optimizations that you can perform to achieve the best performance on [NVIDIA GPU instances \(p. 321\)](#). With some of these instance types, the NVIDIA driver uses an autoboot feature, which varies the GPU clock speeds. By disabling autoboot and setting the GPU clock speeds to their maximum frequency, you can consistently achieve the maximum performance with your GPU instances.

The following steps are for optimizing GPU settings on a Windows instance. For Linux instances, see [Optimize GPU settings](#) in the *Amazon EC2 User Guide for Linux Instances*.

To optimize GPU settings

1. Open a PowerShell window and navigate to the NVIDIA installation folder.

```
cd "C:\Windows\System32\DriverStore\FileRepository\nvgrid*\"
```

2. [G2, G3, and P2 instances only] Disable the autoboot feature for all GPUs on the instance.

```
.\nvidia-smi --auto-boost-default=0
```

3. Set all GPU clock speeds to their maximum frequency. Use the memory and graphics clock speeds specified in the following commands.

Some versions of the NVIDIA driver do not support setting the application clock speed, and display the error "Setting applications clocks is not supported for GPU...", which you can ignore.

- G3 instances:

```
.\nvidia-smi -ac "2505,1177"
```

- G4dn instances:

```
.\nvidia-smi -ac "5001,1590"
```

- G5 instances:

```
.\nvidia-smi -ac "6250,1710"
```

- P2 instances:

```
.\nvidia-smi -ac "2505,875"
```

- P3 and P3dn instances:

```
.\nvidia-smi -ac "877,1530"
```

Find an Amazon EC2 instance type

Before you can launch an instance, you must select an instance type to use. The instance type that you choose might depend on the resources that your workload requires, such as compute, memory, or storage resources. It can be beneficial to identify several instance types that might suit your workload and evaluate their performance in a test environment. There is no substitute for measuring the performance of your application under load.

If you already have running EC2 instances, you can use AWS Compute Optimizer to get recommendations about the instance types that you should use to improve performance, save money, or both. For more information, see [the section called “Get recommendations” \(p. 341\)](#).

Tasks

- [Find an instance type using the console \(p. 340\)](#)
- [Find an instance type using the AWS CLI \(p. 341\)](#)

Find an instance type using the console

You can find an instance type that meets your needs using the Amazon EC2 console.

To find an instance type using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. In the navigation pane, choose **Instance Types**.
4. (Optional) Choose the preferences (gear) icon to select which instance type attributes to display, such as **On-Demand Linux pricing**, and then choose **Confirm**. Alternatively, select the name of an instance type to open its details page and view all attributes available through the console. The console does not display all the attributes available through the API or the command line.
5. Use the instance type attributes to filter the list of displayed instance types to only the instance types that meet your needs. For example, you can filter on the following attributes:
 - **Availability zones** – The name of the Availability Zone, Local Zone, or Wavelength Zone. For more information, see [the section called “Regions and Zones” \(p. 1221\)](#).
 - **vCPUs or Cores** – The number of vCPUs or cores.
 - **Memory (GiB)** – The memory size, in GiB.
 - **Network performance** – The network performance, in Gigabits.
 - **Local instance storage** – Indicates whether the instance type has local instance storage (true | false).
6. (Optional) To see a side-by-side comparison, select the checkbox for multiple instance types. The comparison is displayed at the bottom of the screen.
7. (Optional) To save the list of instance types to a comma-separated values (.csv) file for further review, choose **Actions, Download list CSV**. The file includes all instance types that match the filters you set.

8. (Optional) To launch instances using an instance type that meet your needs, select the checkbox for the instance type and choose **Actions, Launch instance**. For more information, see [Launch an instance using the new launch instance wizard \(p. 552\)](#).

Find an instance type using the AWS CLI

You can use AWS CLI commands for Amazon EC2 to find an instance type that meet your needs.

To find an instance type using the AWS CLI

1. If you have not done so already, install the AWS CLI. For more information, see the [AWS Command Line Interface User Guide](#).
2. Use the [describe-instance-types](#) command to filter instance types based on instance attributes. For example, you can use the following command to display only current generation instance types with 64 GiB (65536 MiB) of memory.

```
aws ec2 describe-instance-types --filters "Name=current-generation,Values=true"  
"Name=memory-info.size-in-mib,Values=65536" --query "InstanceTypes[*].[InstanceType]"  
--output text | sort
```

3. Use the [describe-instance-type-offerings](#) command to filter instance types offered by location (Region or Zone). For example, you can use the following command to display the instance types offered in the specified Zone.

```
aws ec2 describe-instance-type-offerings --location-type "availability-zone" --filters  
Name=location,Values=us-east-2a --region us-east-2 --query "InstanceTypeOfferings[*].  
[InstanceType]" --output text | sort
```

4. After locating the instance types that meet your needs, save the list so that you can use these instance types when you launch instances. For more information, see [Launching your instance](#) in the *AWS Command Line Interface User Guide*.

Get recommendations for an instance type

AWS Compute Optimizer provides Amazon EC2 instance recommendations to help you improve performance, save money, or both. You can use these recommendations to decide whether to move to a new instance type.

To make recommendations, Compute Optimizer analyzes your existing instance specifications and utilization metrics. The compiled data is then used to recommend which Amazon EC2 instance types are best able to handle the existing workload. Recommendations are returned along with per-hour instance pricing.

This topic outlines how to view recommendations through the Amazon EC2 console. For more information, see the [AWS Compute Optimizer User Guide](#).

Note

To get recommendations from Compute Optimizer, you must first opt in to Compute Optimizer. For more information, see [Getting Started with AWS Compute Optimizer](#) in the *AWS Compute Optimizer User Guide*.

Contents

- [Limitations \(p. 342\)](#)
- [Findings \(p. 342\)](#)
- [View recommendations \(p. 342\)](#)

- [Considerations for evaluating recommendations \(p. 343\)](#)
- [Additional resources \(p. 344\)](#)

Limitations

Compute Optimizer currently generates recommendations for C, D, H, I, M, R, T, X, and z instance types. Other instance types are not considered by Compute Optimizer. If you're using other instance types, they will not be listed in the Compute Optimizer recommendations view. For more information about the supported and unsupported instance types, see [Amazon EC2 instance requirements](#) in the *AWS Compute Optimizer User Guide*.

Findings

Compute Optimizer classifies its findings for EC2 instances as follows:

- **Under-provisioned** – An EC2 instance is considered under-provisioned when at least one specification of your instance, such as CPU, memory, or network, does not meet the performance requirements of your workload. Under-provisioned EC2 instances might lead to poor application performance.
- **Over-provisioned** – An EC2 instance is considered over-provisioned when at least one specification of your instance, such as CPU, memory, or network, can be sized down while still meeting the performance requirements of your workload, and when no specification is under-provisioned. Over-provisioned EC2 instances might lead to unnecessary infrastructure cost.
- **Optimized** – An EC2 instance is considered optimized when all specifications of your instance, such as CPU, memory, and network, meet the performance requirements of your workload, and the instance is not over-provisioned. An optimized EC2 instance runs your workloads with optimal performance and infrastructure cost. For optimized instances, Compute Optimizer might sometimes recommend a new generation instance type.
- **None** – There are no recommendations for this instance. This might occur if you've been opted in to Compute Optimizer for less than 12 hours, or when the instance has been running for less than 30 hours, or when the instance type is not supported by Compute Optimizer. For more information, see [Limitations \(p. 342\)](#) in the previous section.

View recommendations

After you opt in to Compute Optimizer, you can view the findings that Compute Optimizer generates for your EC2 instances in the EC2 console. You can then access the Compute Optimizer console to view the recommendations. If you recently opted in, findings might not be reflected in the EC2 console for up to 12 hours.

To view a recommendation for an EC2 instance through the EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, and then choose the instance ID .
3. On the instance summary page, in the **AWS Compute Optimizer** banner near the bottom of the page, choose **View detail**.

The instance opens in Compute Optimizer, where it is labeled as the **Current** instance. Up to three different instance type recommendations, labeled **Option 1**, **Option 2**, and **Option 3**, are provided. The bottom half of the window shows recent CloudWatch metric data for the current instance: **CPU utilization**, **Memory utilization**, **Network in**, and **Network out**.

4. (Optional) In the Compute Optimizer console, choose the settings icon () to change the visible columns in the table, or to view the public pricing information for a different purchasing option for the current and recommended instance types.

Note

If you've purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.

Determine whether you want to use one of the recommendations. Decide whether to optimize for performance improvement, for cost reduction, or for a combination of the two. For more information, see [Viewing Resource Recommendations](#) in the *AWS Compute Optimizer User Guide*.

To view recommendations for all EC2 instances across all Regions through the Compute Optimizer console

1. Open the Compute Optimizer console at <https://console.aws.amazon.com/compute-optimizer/>.
2. Choose **View recommendations for all EC2 instances**.
3. You can perform the following actions on the recommendations page:
 - a. To filter recommendations to one or more AWS Regions, enter the name of the Region in the **Filter by one or more Regions** text box, or choose one or more Regions in the drop-down list that appears.
 - b. To view recommendations for resources in another account, choose **Account**, and then select a different account ID.

This option is available only if you are signed in to a management account of an organization, and you opted in all member accounts within the organization.
 - c. To clear the selected filters, choose **Clear filters**.
 - d. To change the purchasing option that is displayed for the current and recommended instance types, choose the settings icon () , and then choose **On-Demand Instances, Reserved Instances, standard 1-year no upfront**, or **Reserved Instances, standard 3-year no upfront**.
 - e. To view details, such as additional recommendations and a comparison of utilization metrics, choose the finding (**Under-provisioned**, **Over-provisioned**, or **Optimized**) listed next to the desired instance. For more information, see [Viewing Resource Details](#) in the *AWS Compute Optimizer User Guide*.

Considerations for evaluating recommendations

Before changing an instance type, consider the following:

- The recommendations don't forecast your usage. Recommendations are based on your historical usage over the most recent 14-day time period. Be sure to choose an instance type that is expected to meet your future resource needs.
- Focus on the graphed metrics to determine whether actual usage is lower than instance capacity. You can also view metric data (average, peak, percentile) in CloudWatch to further evaluate your EC2 instance recommendations. For example, notice how CPU percentage metrics change during the day and whether there are peaks that need to be accommodated. For more information, see [Viewing Available Metrics](#) in the *Amazon CloudWatch User Guide*.
- Compute Optimizer might supply recommendations for burstable performance instances, which are T3, T3a, and T2 instances. If you periodically burst above the baseline, make sure that you can continue to do so based on the vCPUs of the new instance type. For more information, see [Key concepts and definitions for burstable performance instances \(p. 247\)](#).
- If you've purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.

- Consider conversions to newer generation instances, where possible.
- When migrating to a different instance family, make sure the current instance type and the new instance type are compatible, for example, in terms of virtualization, architecture, or network type. For more information, see [Compatibility for changing the instance type \(p. 347\)](#).
- Finally, consider the performance risk rating that's provided for each recommendation. Performance risk indicates the amount of effort you might need to spend in order to validate whether the recommended instance type meets the performance requirements of your workload. We also recommend rigorous load and performance testing before and after making any changes.

There are other considerations when resizing an EC2 instance. For more information, see [Change the instance type \(p. 344\)](#).

Additional resources

For more information:

- [Instance types \(p. 210\)](#)
- [AWS Compute Optimizer User Guide](#)

Change the instance type

As your needs change, you might find that your instance is over-utilized (the instance type is too small) or under-utilized (the instance type is too large). If this is the case, you can resize your instance by changing its instance type. For example, if your t2.micro instance is too small for its workload, you can increase its size by changing it to a bigger T2 instance type, such as t2.large. Or you can change it to another instance type, such as m5.large. You might also want to change from a previous generation to a current generation instance type to take advantage of some features, such as support for IPv6.

If you want a recommendation for an instance type that is best able to handle your existing workload, you can use AWS Compute Optimizer. For more information, see [Get recommendations for an instance type \(p. 341\)](#).

When you change the instance type, you'll start paying the rate of the new instance type. For the on-demand rates of all instance types, see [Amazon EC2 On-Demand Pricing](#).

If you want to add additional storage to your instance without changing the instance type, see [Attach an Amazon EBS volume to an instance \(p. 1729\)](#).

Which instructions to follow?

There are different instructions for changing the instance type. The instructions to use depend on whether the instance type is compatible with the instance's current configuration. For information about how compatibility is determined, see [Compatibility for changing the instance type \(p. 347\)](#).

Use the following table to determine which instructions to follow.

Compatibility	Use these instructions
Compatible	Change the instance type of an existing instance (p. 345)
Not compatible	Change the instance type by launching a new instance (p. 346)

Considerations for compatible instance types

Consider the following when changing the instance type of an existing instance:

- We recommend that you update the AWS PV driver package before changing the instance type. For more information, see [Upgrade PV drivers on Windows instances \(p. 786\)](#).
- You must stop your Amazon EBS-backed instance before you can change its instance type. Ensure that you plan for downtime while your instance is stopped. Stopping the instance and changing its instance type might take a few minutes, and restarting your instance might take a variable amount of time depending on your application's startup scripts. For more information, see [Stop and start your instance \(p. 594\)](#).
- When you stop and start an instance, we move the instance to new hardware. If your instance has a public IPv4 address, we release the address and give your instance a new public IPv4 address. If you require a public IPv4 address that does not change, use an [Elastic IP address \(p. 1269\)](#).
- You can't change the instance type if [hibernation \(p. 602\)](#) is enabled for the instance.
- You can't change the instance type of a [Spot Instance \(p. 419\)](#).
- If your instance is in an Auto Scaling group, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and may terminate it and launch a replacement instance. To prevent this, you can suspend the scaling processes for the group while you're changing the instance type. For more information, see [Suspending and resuming a process for an Auto Scaling group](#) in the *Amazon EC2 Auto Scaling User Guide*.
- When you change the instance type of an instance with NVMe instance store volumes, the updated instance might have additional instance store volumes, because all NVMe instance store volumes are available even if they are not specified in the AMI or instance block device mapping. Otherwise, the updated instance has the same number of instance store volumes that you specified when you launched the original instance.
- The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. You can't change to an instance type or instance size that does not support the number of volumes that are already attached to your instance. For more information, see [Instance volume limits \(p. 2019\)](#).

Change the instance type of an existing instance

Use the following instructions to change the instance type of an instance if the instance type that you need is compatible with the instance's current configuration.

To change the instance type of an Amazon EBS-backed instance

1. (Optional) If the new instance type requires drivers that are not installed on the existing instance, you must connect to your instance and install the drivers first. For more information, see [Compatibility for changing the instance type \(p. 347\)](#).
2. (Optional) If you configured your Windows instance to use [static IP addressing \(p. 849\)](#) and you change from an instance type that doesn't support enhanced networking to an instance type that does support enhanced networking, you might get a warning about a potential IP address conflict when you reconfigure static IP addressing. To prevent this, enable DHCP on the network interface for your instance before you change the instance type. From your instance, open the **Network and Sharing Center**, open **Internet Protocol Version 4 (TCP/IPv4) Properties** for the network interface, and choose **Obtain an IP address automatically**. Change the instance type and reconfigure static IP addressing on the network interface.
3. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
4. In the navigation pane, choose **Instances**.
5. Select the instance and choose **Instance state, Stop instance**. When prompted for confirmation, choose **Stop**. It can take a few minutes for the instance to stop.

6. With the instance still selected, choose **Actions, Instance settings, Change instance type**. This option is grayed out if the instance state is not stopped.
7. On the **Change instance type** page, do the following:
 - a. For **Instance type**, select the instance type that you want.
If the instance type is not in the list, then it's not compatible with the configuration of your instance. Instead, use the following instructions: [Change the instance type by launching a new instance \(p. 346\)](#).
 - b. (Optional) If the instance type that you selected supports EBS optimization, select **EBS-optimized** to enable EBS optimization, or deselect **EBS-optimized** to disable EBS optimization. If the instance type that you selected is EBS optimized by default, **EBS-optimized** is selected and you can't deselect it.
 - c. Choose **Apply** to accept the new settings.
8. To start the instance, select the instance and choose **Instance state, Start instance**. It can take a few minutes for the instance to enter the running state. If your instance won't start, see [Troubleshoot changing the instance type \(p. 349\)](#).
9. [Windows Server 2016 and later] Connect to your Windows instance and run the following EC2Launch PowerShell script to configure the instance after the instance type is changed.

Important

The administrator password will reset when you enable the initialize instance EC2 Launch script. You can modify the configuration file to disable the administrator password reset by specifying it in the settings for the initialization tasks. For steps on how to disable password reset, see [Configure initialization tasks \(p. 747\)](#).

```
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -  
Schedule
```

Change the instance type by launching a new instance

If the current configuration of your EBS-backed instance is incompatible with the new instance type that you want, then you can't change the instance type of the original instance. Instead, you must launch a new instance with a configuration that is compatible with the new instance type that you want, and then migrate your application to the new instance. For information about how compatibility is determined, see [Compatibility for changing the instance type \(p. 347\)](#).

To migrate your application to a new instance, do the following:

- Back up the data on your original instance.
- Launch a new instance with a configuration that is compatible with the new instance type that you want, and attach any EBS volumes that were attached to your original instance.
- Install your application and any software on your new instance.
- Restore any data.
- If your original instance has an Elastic IP address, and you want to ensure that your users can continue uninterrupted to use the applications on your new instance, you must associate the Elastic IP address with your new instance. For more information, see [Elastic IP address \(p. 1269\)](#).

To change the instance type for a new instance configuration

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Back up data that you need to keep, as follows:
 - For data on your instance store volumes, back up the data to persistent storage.

- For data on your EBS volumes, [take a snapshot of the volumes \(p. 1762\)](#) or [detach the volumes from the instance \(p. 1752\)](#) so that you can attach them to the new instance later.
3. In the navigation pane, choose **Instances**.
 4. Choose **Launch instances**. When you configure the instance, do the following:
 - a. Select an AMI that will support the instance type that you want.
 - b. Select the new instance type that you want. If the instance type that you want isn't available, then it's not compatible with the configuration of the AMI that you selected.
 - c. If you're using an Elastic IP address, select the VPC that the original instance is currently running in.
 - d. If you want to allow the same traffic to reach the new instance, select the security group that is associated with the original instance.
 - e. When you're done configuring your new instance, complete the steps to select a key pair and launch your instance. It can take a few minutes for the instance to enter the `running` state.
 5. If required, [attach any new EBS volumes \(p. 1729\)](#) based on the snapshots that you created, or any EBS volumes that you detached from the original instance, to the new instance.
 6. Install your application and any required software on the new instance.
 7. Restore any data that you backed up from the instance store volumes of the original instance.
 8. If you are using an Elastic IP address, assign it to the new instance as follows:
 - a. In the navigation pane, choose **Elastic IPs**.
 - b. Select the Elastic IP address that is associated with the original instance and choose **Actions**, **Disassociate Elastic IP address**. When prompted for confirmation, choose **Disassociate**.
 - c. With the Elastic IP address still selected, choose **Actions**, **Associate Elastic IP address**.
 - d. For **Resource type**, choose **Instance**.
 - e. For **Instance**, choose the new instance with which to associate the Elastic IP address.
 - f. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
 - g. Choose **Associate**.
 9. (Optional) You can terminate the original instance if it's no longer needed. Select the instance, verify that you are about to terminate the original instance and not the new instance (for example, check the name or launch time), and then choose **Instance state**, **Terminate instance**.

Compatibility for changing the instance type

You can change the instance type only if the instance's current configuration is compatible with the instance type that you want. If the instance type that you want is not compatible with the instance's current configuration, you must launch a new instance with a configuration that is compatible with the instance type, and then migrate your application to the new instance.

For compatibility information for changing Linux instance types, see [Compatibility for changing the instance type](#) in the *User Guide for Linux Instances*.

Tip

For additional guidance on migrating compatible Windows instances from a Xen instance type to a Nitro instance type, see [Migrate to latest generation instance types \(p. 940\)](#).

Compatibility is determined in the following ways:

Architecture

AMIs are specific to the architecture of the processor, so you must select an instance type with the same processor architecture as the current instance type. For example:

- If the current instance type has a processor based on the Arm architecture, you are limited to the instance types that support a processor based on the Arm architecture, such as C6g and M6g.
- The following instance types are the only instance types that support 32-bit AMIs: t2.nano, t2.micro, t2.small, t2.medium, c3.large, t1.micro, m1.small, m1.medium, and c1.medium. If you are changing the instance type of a 32-bit instance, you are limited to these instance types.

Network adapters

If you switch from a driver for one network adapter to another, the network adapter settings are reset when the operating system creates the new adapter. To reconfigure the settings, you might need access to a local account with administrator permissions. The following are examples of moving from one network adapter to another:

- AWS PV (T2 instances) to Intel 82599 VF (M4 instances)
- Intel 82599 VF (most M4 instances) to ENA (M5 instances)
- ENA (M5 instances) to high-bandwidth ENA (M5n instances)

Enhanced networking

Instance types that support [enhanced networking \(p. 1326\)](#) require the necessary drivers installed. For example, instances based on the [Nitro System \(p. 218\)](#) require EBS-backed AMIs with the Elastic Network Adapter (ENA) drivers installed. To change from an instance type that does not support enhanced networking to an instance type that supports enhanced networking, you must install the [ENA drivers \(p. 1327\)](#) or [ixgbefv drivers \(p. 1345\)](#) on the instance, as appropriate.

Note

When you resize an instance with ENA Express enabled, the new instance type must also support ENA Express. For a list of instance types that support ENA Express, see [Supported instance types for ENA Express \(p. 1340\)](#).

To change from an instance type that supports ENA Express to an instance type that does not support it, ensure that ENA Express is not currently enabled before you resize the instance.

NVMe

EBS volumes are exposed as NVMe block devices on instances built on the [Nitro System \(p. 218\)](#). If you change from an instance type that does not support NVMe to an instance type that supports NVMe, you must first install the [NVMe drivers \(p. 1939\)](#) on your instance. Also, the device names for devices that you specify in the block device mapping are renamed using NVMe device names (/dev/nvme[0-26]n1).

Volumes limits

The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. For more information, see [Instance volume limits \(p. 2019\)](#).

You can only change to an instance type or instance size that supports the same number or a larger number of volumes than is currently attached to the instance. If you change to an instance type or instance size that does not support the number of currently attached volumes, the request fails. For example, if you change from an m7i.4xlarge instance with 32 attached volumes to an m6i.4xlarge, which supports a maximum of 27 volumes, the request fails.

AMI

For information about the AMIs required by instance types that support enhanced networking and NVMe, see the Release Notes in the following documentation:

- [General purpose instances \(p. 224\)](#)
- [Compute optimized instances \(p. 279\)](#)
- [Memory optimized instances \(p. 291\)](#)

- [Storage optimized instances \(p. 313\)](#)

Troubleshoot changing the instance type

Use the following information to help diagnose and fix issues that you might encounter when changing the instance type.

Instance won't start after changing instance type

Possible cause: AMI does not support instance type

If you use the EC2 console to change the instance type, only the instance types that are supported by the selected AMI are available. However, if you use the AWS CLI to launch an instance, you can specify an incompatible AMI and instance type. If the AMI and instance type are incompatible, the instance can't start. For more information, see [Compatibility for changing the instance type \(p. 347\)](#).

Possible cause: Instance is in cluster placement group

If your instance is in a [cluster placement group \(p. 1352\)](#) and, after changing the instance type, the instance fails to start, try the following:

1. Stop all the instances in the cluster placement group.
2. Change the instance type of the affected instance.
3. Start all the instances in the cluster placement group.

Application or website not reachable from the internet after changing instance type

Possible cause: Public IPv4 address is released

When you change the instance type, you must first stop the instance. When you stop an instance, we release the public IPv4 address and give your instance a new public IPv4 address.

To retain the public IPv4 address between instance stops and starts, we recommend that you use an Elastic IP address, at no extra cost provided your instance is running. For more information, see [Elastic IP addresses \(p. 1269\)](#).

Instance purchasing options

Amazon EC2 provides the following purchasing options to enable you to optimize your costs based on your needs:

- [On-Demand Instances \(p. 351\)](#) – Pay, by the second, for the instances that you launch.
- [Savings Plans](#) – Reduce your Amazon EC2 costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years.
- [Reserved Instances \(p. 353\)](#) – Reduce your Amazon EC2 costs by making a commitment to a consistent instance configuration, including instance type and Region, for a term of 1 or 3 years.
- [Spot Instances \(p. 394\)](#) – Request unused EC2 instances, which can reduce your Amazon EC2 costs significantly.
- [Dedicated Hosts \(p. 458\)](#) – Pay for a physical host that is fully dedicated to running your instances, and bring your existing per-socket, per-core, or per-VM software licenses to reduce costs.
- [Dedicated Instances \(p. 499\)](#) – Pay, by the hour, for instances that run on single-tenant hardware.

- [Capacity Reservations \(p. 504\)](#) – Reserve capacity for your EC2 instances in a specific Availability Zone for any duration.

If you require a capacity reservation, purchase Reserved Instances or Capacity Reservations for a specific Availability Zone. Spot Instances are a cost-effective choice if you can be flexible about when your applications run and if they can be interrupted. Dedicated Hosts or Dedicated Instances can help you address compliance requirements and reduce costs by using your existing server-bound software licenses. For more information, see [Amazon EC2 Pricing](#).

For more information about Savings Plans, see the [Savings Plans User Guide](#).

Contents

- [Determine the instance lifecycle \(p. 350\)](#)
- [On-Demand Instances \(p. 351\)](#)
- [Reserved Instances \(p. 353\)](#)
- [Spot Instances \(p. 394\)](#)
- [Dedicated Hosts \(p. 458\)](#)
- [Dedicated Instances \(p. 499\)](#)
- [On-Demand Capacity Reservations \(p. 504\)](#)

Determine the instance lifecycle

The lifecycle of an instance starts when it is launched and ends when it is terminated. The purchasing option that you choose affects the lifecycle of the instance. For example, an On-Demand Instance runs when you launch it and ends when you terminate it. A Spot Instance runs as long as capacity is available and your maximum price is higher than the Spot price.

Use one of the following methods to determine the lifecycle of an instance.

To determine the instance lifecycle using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. On the **Details** tab, under **Instance details**, find **Lifecycle**. If the value is spot, the instance is a Spot Instance. If the value is normal, the instance is either an On-Demand Instance or a Reserved Instance.
5. On the **Details** tab, under **Host and placement group**, find **Tenancy**. If the value is host, the instance is running on a Dedicated Host. If the value is dedicated, the instance is a Dedicated Instance.
6. (Optional) If you have purchased a Reserved Instance and want to verify that it is being applied, you can check the usage reports for Amazon EC2. For more information, see [Amazon EC2 usage reports \(p. 2102\)](#).

To determine the instance lifecycle using the AWS CLI

Use the following [describe-instances](#) command:

```
aws ec2 describe-instances --instance-ids i-1234567890abcdef0
```

If the instance is running on a Dedicated Host, the output contains the following information:

```
"Tenancy": "host"
```

If the instance is a Dedicated Instance, the output contains the following information:

```
"Tenancy": "dedicated"
```

If the instance is a Spot Instance, the output contains the following information:

```
"InstanceLifecycle": "spot"
```

Otherwise, the output does not contain InstanceLifecycle.

On-Demand Instances

With On-Demand Instances, you pay for compute capacity by the second with no long-term commitments. You have full control over the instance's lifecycle—you decide when to launch, stop, hibernate, start, reboot, or terminate it.

There is no long-term commitment required when you purchase On-Demand Instances. You pay only for the seconds that your On-Demand Instances are in the running state, with a 60-second minimum. The price per second for a running On-Demand Instance is fixed, and is listed on the [Amazon EC2 Pricing, On-Demand Pricing page](#).

We recommend that you use On-Demand Instances for applications with short-term, irregular workloads that cannot be interrupted.

For significant savings over On-Demand Instances, use [AWS Savings Plans, Spot Instances \(p. 394\)](#), or [Reserved Instances \(p. 353\)](#).

Contents

- [Work with On-Demand Instances \(p. 351\)](#)
- [On-Demand Instance quotas \(p. 352\)](#)
 - [Monitor On-Demand Instance quotas and usage \(p. 352\)](#)
 - [Request a quota increase \(p. 353\)](#)
- [Query the prices of On-Demand Instances \(p. 353\)](#)

Work with On-Demand Instances

You can work with On-Demand Instances in the following ways:

- [Launch your instance \(p. 551\)](#)
- [Connect to your Windows instance \(p. 626\)](#)
- [Stop and start your instance \(p. 594\)](#)
- [Hibernate your On-Demand Windows instance \(p. 602\)](#)
- [Reboot your instance \(p. 612\)](#)
- [Instance retirement \(p. 613\)](#)
- [Terminate your instance \(p. 615\)](#)
- [Recover your instance \(p. 622\)](#)
- [Configure your Windows instance \(p. 691\)](#)
- [Identify EC2 Windows instances \(p. 953\)](#)

If you're new to Amazon EC2, see [Get started with Amazon EC2 \(p. 3\)](#).

On-Demand Instance quotas

There are quotas for the number of running On-Demand Instances per AWS account per Region. On-Demand Instance quotas are managed in terms of the *number of virtual central processing units (vCPUs)* that your running On-Demand Instances are using, regardless of the instance type.

We provide the following quota types for On-Demand Instances:

- Running On-Demand DL instances
- Running On-Demand F instances
- Running On-Demand G and VT instances
- Running On-Demand High Memory instances
- Running On-Demand HPC instances
- Running On-Demand Inf instances
- Running On-Demand P instances
- Running On-Demand Standard (A, C, D, H, I, M, R, T, Z) instances
- Running On-Demand Trn instances
- Running On-Demand X instances

Quotas apply to running instances only. If your instance is pending, stopping, stopped, or hibernated, it does not count towards your quota.

Each quota type specifies the maximum number of vCPUs for one or more instance families. For information about the different instance families, generations, and sizes, see [Amazon EC2 Instance Types](#).

You can launch any combination of instance types that meet your changing application needs, as long as the number of vCPUs does not exceed your account quota. For example, with a Standard instance quota of 256 vCPUs, you could launch 32 m5.2xlarge instances (32 x 8 vCPUs) or 16 c5.4xlarge instances (16 x 16 vCPUs). For more information, see [EC2 On-Demand Instance limits](#).

Tasks

- [Monitor On-Demand Instance quotas and usage \(p. 352\)](#)
- [Request a quota increase \(p. 353\)](#)

Monitor On-Demand Instance quotas and usage

You can view and manage your On-Demand Instance quotas for each Region using the following methods.

To view your current quotas using the Service Quotas console

1. Open the Service Quotas console at <https://console.aws.amazon.com/servicequotas/home/services/ec2/quotas/>.
2. From the navigation bar, select a Region.
3. In the filter field, enter **On-Demand**.
4. The **Applied quota value** column displays the maximum number of vCPUs for each On-Demand Instance quota type for your account.

To view your current quotas using the AWS Trusted Advisor console

Open [Service limits page](#) in the AWS Trusted Advisor console.

To configure CloudWatch alarms

With Amazon CloudWatch metrics integration, you can monitor your EC2 usage against your quotas. You can also configure alarms to warn about approaching quotas. For more information, see [Service Quotas and Amazon CloudWatch alarms](#) in the *Service Quotas User Guide*.

Request a quota increase

Even though Amazon EC2 automatically increases your On-Demand Instance quotas based on your usage, you can request a quota increase if necessary. For example, if you intend to launch more instances than your current quota allows, you can request a quota increase by using the Service Quotas console described in [Amazon EC2 service quotas \(p. 2100\)](#).

Query the prices of On-Demand Instances

You can use the Price List Service API or the AWS Price List API to query the prices of On-Demand Instances. For more information, see [Using the AWS Price List API](#) in the *AWS Billing User Guide*.

Reserved Instances

Reserved Instances provide you with significant savings on your Amazon EC2 costs compared to On-Demand Instance pricing. Reserved Instances are not physical instances, but rather a billing discount applied to the use of On-Demand Instances in your account. These On-Demand Instances must match certain attributes, such as instance type and Region, in order to benefit from the billing discount.

Note

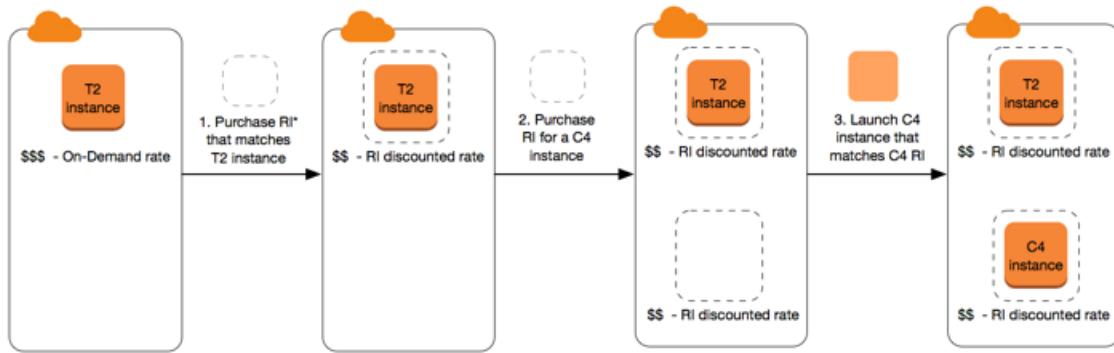

Savings Plans also offer significant savings on your Amazon EC2 costs compared to On-Demand Instance pricing. With Savings Plans, you make a commitment to a consistent usage amount, measured in USD per hour. This provides you with the flexibility to use the instance configurations that best meet your needs and continue to save money, instead of making a commitment to a specific instance configuration. For more information, see the [AWS Savings Plans User Guide](#).

Reserved Instances topics

- [Reserved Instance overview \(p. 353\)](#)

- [Exchange Convertible Reserved Instances \(p. 387\)](#)
- [Reserved Instance quotas \(p. 391\)](#)

Reserved Instance overview

The following diagram shows a basic overview of purchasing and using Reserved Instances.

*RI = Reserved Instance

In this scenario, you have a running On-Demand Instance (T2) in your account, for which you're currently paying On-Demand rates. You purchase a Reserved Instance that matches the attributes of your running instance, and the billing benefit is immediately applied. Next, you purchase a Reserved Instance for a C4 instance. You do not have any running instances in your account that match the attributes of this Reserved Instance. In the final step, you launch an instance that matches the attributes of the C4 Reserved Instance, and the billing benefit is immediately applied.

Key variables that determine Reserved Instance pricing

The Reserved Instance pricing is determined by the following key variables.

Instance attributes

A Reserved Instance has four instance attributes that determine its price.

- **Instance type:** For example, m4.large. This is composed of the instance family (for example, m4) and the instance size (for example, large).
- **Region:** The Region in which the Reserved Instance is purchased.
- **Tenancy:** Whether your instance runs on shared (default) or single-tenant (dedicated) hardware. For more information, see [Dedicated Instances \(p. 499\)](#).
- **Platform:** The operating system; for example, Windows or Linux/Unix. For more information, see [Choosing a platform \(p. 369\)](#).

Term commitment

You can purchase a Reserved Instance for a one-year or three-year commitment, with the three-year commitment offering a bigger discount.

- **One-year:** A year is defined as 31536000 seconds (365 days).
- **Three-year:** Three years is defined as 94608000 seconds (1095 days).

Reserved Instances do not renew automatically; when they expire, you can continue using the EC2 instance without interruption, but you are charged On-Demand rates. In the above example, when the Reserved Instances that cover the T2 and C4 instances expire, you go back to paying the On-Demand rates until you terminate the instances or purchase new Reserved Instances that match the instance attributes.

Important

After you purchase a Reserved Instance, you cannot cancel your purchase. However, you might be able to [modify \(p. 383\)](#), [exchange \(p. 387\)](#), or [sell \(p. 377\)](#) your Reserved Instance if your needs change.

Payment options

The following payment options are available for Reserved Instances:

- **All Upfront:** Full payment is made at the start of the term, with no other costs or additional hourly charges incurred for the remainder of the term, regardless of hours used.
- **Partial Upfront:** A portion of the cost must be paid upfront and the remaining hours in the term are billed at a discounted hourly rate, regardless of whether the Reserved Instance is being used.
- **No Upfront:** You are billed a discounted hourly rate for every hour within the term, regardless of whether the Reserved Instance is being used. No upfront payment is required.

Note

No Upfront Reserved Instances are based on a contractual obligation to pay monthly for the entire term of the reservation. For this reason, a successful billing history is required before you can purchase No Upfront Reserved Instances.

Generally speaking, you can save more money making a higher upfront payment for Reserved Instances. You can also find Reserved Instances offered by third-party sellers at lower prices and shorter term lengths on the Reserved Instance Marketplace. For more information, see [Sell in the Reserved Instance Marketplace \(p. 377\)](#).

Offering class

If your computing needs change, you might be able to modify or exchange your Reserved Instance, depending on the offering class.

- **Standard:** These provide the most significant discount, but can only be modified. Standard Reserved Instances can't be exchanged.
- **Convertible:** These provide a lower discount than Standard Reserved Instances, but can be exchanged for another Convertible Reserved Instance with different instance attributes. Convertible Reserved Instances can also be modified.

For more information, see [Types of Reserved Instances \(offering classes\) \(p. 356\)](#).

Important

After you purchase a Reserved Instance, you cannot cancel your purchase. However, you might be able to [modify \(p. 383\)](#), [exchange \(p. 387\)](#), or [sell \(p. 377\)](#) your Reserved Instance if your needs change.

For more information, see the [Amazon EC2 Reserved Instances Pricing page](#).

Regional and zonal Reserved Instances (scope)

When you purchase a Reserved Instance, you determine the scope of the Reserved Instance. The scope is either regional or zonal.

- **Regional:** When you purchase a Reserved Instance for a Region, it's referred to as a *regional* Reserved Instance.
- **Zonal:** When you purchase a Reserved Instance for a specific Availability Zone, it's referred to as a *zonal* Reserved Instance.

The scope does not affect the price. You pay the same price for a regional or zonal Reserved Instance. For more information about Reserved Instance pricing, see [Key variables that determine Reserved Instance pricing \(p. 354\)](#) and [Amazon EC2 Reserved Instances Pricing](#).

For more information about how to specify the scope of a Reserved Instance, see [RI Attributes](#), specifically the **Availability Zone** bullet.

Differences between regional and zonal Reserved Instances

The following table highlights some key differences between regional Reserved Instances and zonal Reserved Instances:

	Regional Reserved Instances	Zonal Reserved Instances
Ability to reserve capacity	A regional Reserved Instance does <i>not</i> reserve capacity.	A zonal Reserved Instance reserves capacity in the specified Availability Zone.
Availability Zone flexibility	The Reserved Instance discount applies to instance usage in any Availability Zone in the specified Region.	No Availability Zone flexibility—the Reserved Instance discount applies to instance usage in the specified Availability Zone only.
Instance size flexibility	The Reserved Instance discount applies to instance usage within the instance family, regardless of size. Only supported on Amazon Linux/Unix Reserved Instances with default tenancy. For more information, see Instance size flexibility determined by normalization factor (p. 358) .	No instance size flexibility—the Reserved Instance discount applies to instance usage for the specified instance type and size only.
Queuing a purchase	You can queue purchases for regional Reserved Instances.	You can't queue purchases for zonal Reserved Instances.

For more information and examples, see [How Reserved Instances are applied \(p. 357\)](#).

Types of Reserved Instances (offering classes)

The offering class of a Reserved Instance is either Standard or Convertible. A Standard Reserved Instance provides a more significant discount than a Convertible Reserved Instance, but you can't exchange a Standard Reserved Instance. You can exchange Convertible Reserved Instances. You can modify Standard and Convertible Reserved Instances.

The configuration of a Reserved Instance comprises a single instance type, platform, scope, and tenancy over a term. If your computing needs change, you might be able to modify or exchange your Reserved Instance.

Differences between Standard and Convertible Reserved Instances

The following are the differences between Standard and Convertible Reserved Instances.

	Standard Reserved Instance	Convertible Reserved Instance
Modify Reserved Instances	Some attributes can be modified. For more information, see Modify Reserved Instances (p. 383) .	Some attributes can be modified. For more information, see Modify Reserved Instances (p. 383) .
Exchange Reserved Instances	Can't be exchanged.	Can be exchanged during the term for another Convertible

	Standard Reserved Instance	Convertible Reserved Instance
		Reserved Instance with new attributes, including instance family, instance type, platform, scope, or tenancy. For more information, see Exchange Convertible Reserved Instances (p. 387) .
Sell in the Reserved Instance Marketplace	Can be sold in the Reserved Instance Marketplace.	Can't be sold in the Reserved Instance Marketplace.
Buy in the Reserved Instance Marketplace	Can be bought in the Reserved Instance Marketplace.	Can't be bought in the Reserved Instance Marketplace.

How Reserved Instances are applied

Reserved Instances are not physical instances, but rather a billing discount that is applied to the running On-Demand Instances in your account. The On-Demand Instances must match certain specifications of the Reserved Instances in order to benefit from the billing discount.

If you purchase a Reserved Instance and you already have a running On-Demand Instance that matches the specifications of the Reserved Instance, the billing discount is applied immediately and automatically. You do not have to restart your instances. If you do not have an eligible running On-Demand Instance, launch an On-Demand Instance with the same specifications as your Reserved Instance. For more information, see [Use your Reserved Instances \(p. 363\)](#).

The offering class (Standard or Convertible) of the Reserved Instance does not affect how the billing discount is applied.

Topics

- [How zonal Reserved Instances are applied \(p. 357\)](#)
- [How regional Reserved Instances are applied \(p. 357\)](#)
- [Instance size flexibility \(p. 358\)](#)
- [Examples of applying Reserved Instances \(p. 360\)](#)

How zonal Reserved Instances are applied

A Reserved Instance that is purchased to reserve capacity in a specific Availability Zone is called a zonal Reserved Instance.

- The Reserved Instance discount applies to matching instance usage in that Availability Zone.
- The attributes (tenancy, platform, Availability Zone, instance type, and instance size) of the running instances must match that of the Reserved Instances.

For example, if you purchase two c4.xlarge default tenancy Linux/Unix Standard Reserved Instances for Availability Zone us-east-1a, then up to two c4.xlarge default tenancy Linux/Unix instances running in the Availability Zone us-east-1a can benefit from the Reserved Instance discount.

How regional Reserved Instances are applied

A Reserved Instance that is purchased for a Region is called a regional Reserved Instance, and provides Availability Zone and instance size flexibility.

- The Reserved Instance discount applies to instance usage in any Availability Zone in that Region.
- The Reserved Instance discount applies to instance usage within the instance family, regardless of size —this is known as [instance size flexibility \(p. 358\)](#).

Instance size flexibility

With instance size flexibility, the Reserved Instance discount applies to instance usage for instances that have the same [family, generation, and attribute \(p. 211\)](#). The Reserved Instance is applied from the smallest to the largest instance size within the instance family based on the normalization factor. For an example of how the Reserved Instance discount is applied, see [Scenario 2: Reserved Instances in a single account using the normalization factor \(p. 361\)](#).

Limitations

- **Supported:** Instance size flexibility is only supported for Regional Reserved Instances.
- **Not supported:** Instance size flexibility is *not supported* for the following Reserved Instances:
 - Reserved Instances that are purchased for a specific Availability Zone (zonal Reserved Instances)
 - Reserved Instances for G4ad, G4dn, G5, G5g, and Inf1 instances
 - Reserved Instances for Windows Server, Windows Server with SQL Standard, Windows Server with SQL Server Enterprise, Windows Server with SQL Server Web, RHEL, and SUSE Linux Enterprise Server
 - Reserved Instances with dedicated tenancy

Instance size flexibility determined by normalization factor

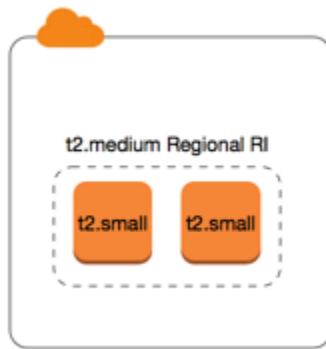

Instance size flexibility is determined by the normalization factor of the instance size. The discount applies either fully or partially to running instances of the same instance family, depending on the instance size of the reservation, in any Availability Zone in the Region. The only attributes that must be matched are the instance family, tenancy, and platform.

The following table lists the different sizes within an instance family, and the corresponding normalization factor. This scale is used to apply the discounted rate of Reserved Instances to the normalized usage of the instance family.

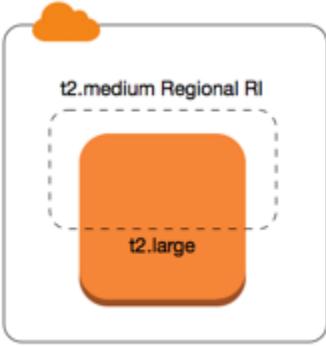

Instance size	Normalization factor
nano	0.25
micro	0.5
small	1
medium	2
large	4
xlarge	8
2xlarge	16
3xlarge	24
4xlarge	32
6xlarge	48

Instance size	Normalization factor
8xlarge	64
9xlarge	72
10xlarge	80
12xlarge	96
16xlarge	128
18xlarge	144
24xlarge	192
32xlarge	256
56xlarge	448
112xlarge	896

For example, a t2.medium instance has a normalization factor of 2. If you purchase a t2.medium default tenancy Amazon Linux/Unix Reserved Instance in the US East (N. Virginia) and you have two running t2.small instances in your account in that Region, the billing benefit is applied in full to both instances.

Or, if you have one t2.large instance running in your account in the US East (N. Virginia) Region, the billing benefit is applied to 50% of the usage of the instance.

The normalization factor is also applied when modifying Reserved Instances. For more information, see [Modify Reserved Instances \(p. 383\)](#).

Normalization factor for bare metal instances

Instance size flexibility also applies to bare metal instances within the instance family. If you have regional Amazon Linux/Unix Reserved Instances with shared tenancy on bare metal instances, you can benefit from the Reserved Instance savings within the same instance family. The opposite is also true: if you have regional Amazon Linux/Unix Reserved Instances with shared tenancy on instances in the same family as a bare metal instance, you can benefit from the Reserved Instance savings on the bare metal instance.

The metal instance size does not have a single normalization factor. A bare metal instance has the same normalization factor as the equivalent virtualized instance size within the same instance family. For example, an `i3.metal` instance has the same normalization factor as an `i3.16xlarge` instance.

Instance size	Normalization factor
<code>m5zn.metal</code> <code>z1d.metal</code>	96
<code>i3.metal</code>	128
<code>c5n.metal</code>	144
<code>c5.metal</code> <code>c5d.metal</code> <code>i3en.metal</code> <code>m5.metal</code> <code>m5d.metal</code> <code>m5dn.metal</code> <code>m5n.metal</code> <code>r5.metal</code> <code>r5b.metal</code> <code>r5d.metal</code> <code>r5dn.metal</code> <code>r5n.metal</code>	192
<code>u-* .metal</code>	896

For example, an `i3.metal` instance has a normalization factor of 128. If you purchase an `i3.metal` default tenancy Amazon Linux/Unix Reserved Instance in the US East (N. Virginia), the billing benefit can apply as follows:

- If you have one running `i3.16xlarge` in your account in that Region, the billing benefit is applied in full to the `i3.16xlarge` instance (`i3.16xlarge` normalization factor = 128).
- Or, if you have two running `i3.8xlarge` instances in your account in that Region, the billing benefit is applied in full to both `i3.8xlarge` instances (`i3.8xlarge` normalization factor = 64).
- Or, if you have four running `i3.4xlarge` instances in your account in that Region, the billing benefit is applied in full to all four `i3.4xlarge` instances (`i3.4xlarge` normalization factor = 32).

The opposite is also true. For example, if you purchase two `i3.8xlarge` default tenancy Amazon Linux/Unix Reserved Instances in the US East (N. Virginia), and you have one running `i3.metal` instance in that Region, the billing benefit is applied in full to the `i3.metal` instance.

Examples of applying Reserved Instances

The following scenarios cover the ways in which Reserved Instances are applied.

- [Scenario 1: Reserved Instances in a single account \(p. 360\)](#)
- [Scenario 2: Reserved Instances in a single account using the normalization factor \(p. 361\)](#)
- [Scenario 3: Regional Reserved Instances in linked accounts \(p. 362\)](#)
- [Scenario 4: Zonal Reserved Instances in a linked account \(p. 363\)](#)

Scenario 1: Reserved Instances in a single account

You are running the following On-Demand Instances in account A:

- 4 x m3.large Linux, default tenancy instances in Availability Zone us-east-1a
- 2 x m4.xlarge Amazon Linux, default tenancy instances in Availability Zone us-east-1b
- 1 x c4.xlarge Amazon Linux, default tenancy instances in Availability Zone us-east-1c

You purchase the following Reserved Instances in account A:

- 4 x m3.large Linux, default tenancy Reserved Instances in Availability Zone us-east-1a (capacity is reserved)
- 4 x m4.large Amazon Linux, default tenancy Reserved Instances in Region us-east-1
- 1 x c4.large Amazon Linux, default tenancy Reserved Instances in Region us-east-1

The Reserved Instance benefits are applied in the following way:

- The discount and capacity reservation of the four m3.large zonal Reserved Instances is used by the four m3.large instances because the attributes (instance size, Region, platform, tenancy) between them match.
- The m4.large regional Reserved Instances provide Availability Zone and instance size flexibility, because they are regional Amazon Linux Reserved Instances with default tenancy.

An m4.large is equivalent to 4 normalized units/hour.

You've purchased four m4.large regional Reserved Instances, and in total, they are equal to 16 normalized units/hour (4x4). Account A has two m4.xlarge instances running, which is equivalent to 16 normalized units/hour (2x8). In this case, the four m4.large regional Reserved Instances provide the full billing benefit to the usage of the two m4.xlarge instances.

- The c4.large regional Reserved Instance in us-east-1 provides Availability Zone and instance size flexibility, because it is a regional Amazon Linux Reserved Instance with default tenancy, and applies to the c4.xlarge instance. A c4.large instance is equivalent to 4 normalized units/hour and a c4.xlarge is equivalent to 8 normalized units/hour.

In this case, the c4.large regional Reserved Instance provides partial benefit to c4.xlarge usage. This is because the c4.large Reserved Instance is equivalent to 4 normalized units/hour of usage, but the c4.xlarge instance requires 8 normalized units/hour. Therefore, the c4.large Reserved Instance billing discount applies to 50% of c4.xlarge usage. The remaining c4.xlarge usage is charged at the On-Demand rate.

Scenario 2: Reserved Instances in a single account using the normalization factor

You are running the following On-Demand Instances in account A:

- 2 x m3.xlarge Amazon Linux, default tenancy instances in Availability Zone us-east-1a
- 2 x m3.large Amazon Linux, default tenancy instances in Availability Zone us-east-1b

You purchase the following Reserved Instance in account A:

- 1 x m3.2xlarge Amazon Linux, default tenancy Reserved Instance in Region us-east-1

The Reserved Instance benefits are applied in the following way:

- The m3.2xlarge regional Reserved Instance in us-east-1 provides Availability Zone and instance size flexibility, because it is a regional Amazon Linux Reserved Instance with default tenancy. It applies first to the m3.large instances and then to the m3.xlarge instances, because it applies from the smallest to the largest instance size within the instance family based on the normalization factor.

An m3.large instance is equivalent to 4 normalized units/hour.

An m3.xlarge instance is equivalent to 8 normalized units/hour.

An m3.2xlarge instance is equivalent to 16 normalized units/hour.

The benefit is applied as follows:

The m3.2xlarge regional Reserved Instance provides full benefit to 2 x m3.large usage, because together these instances account for 8 normalized units/hour. This leaves 8 normalized units/hour to apply to the m3.xlarge instances.

With the remaining 8 normalized units/hour, the m3.2xlarge regional Reserved Instance provides full benefit to 1 x m3.xlarge usage, because each m3.xlarge instance is equivalent to 8 normalized units/hour. The remaining m3.xlarge usage is charged at the On-Demand rate.

Scenario 3: Regional Reserved Instances in linked accounts

Reserved Instances are first applied to usage within the purchasing account, followed by qualifying usage in any other account in the organization. For more information, see [Reserved Instances and consolidated billing \(p. 366\)](#). For regional Reserved Instances that offer instance size flexibility, the benefit is applied from the smallest to the largest instance size within the instance family.

You're running the following On-Demand Instances in account A (the purchasing account):

- 2 x m4.xlarge Linux, default tenancy instances in Availability Zone us-east-1a
- 1 x m4.2xlarge Linux, default tenancy instances in Availability Zone us-east-1b
- 2 x c4.xlarge Linux, default tenancy instances in Availability Zone us-east-1a
- 1 x c4.2xlarge Linux, default tenancy instances in Availability Zone us-east-1b

Another customer is running the following On-Demand Instances in account B—a linked account:

- 2 x m4.xlarge Linux, default tenancy instances in Availability Zone us-east-1a

You purchase the following regional Reserved Instances in account A:

- 4 x m4.xlarge Linux, default tenancy Reserved Instances in Region us-east-1
- 2 x c4.xlarge Linux, default tenancy Reserved Instances in Region us-east-1

The regional Reserved Instance benefits are applied in the following way:

- The discount of the four m4.xlarge Reserved Instances is used by the two m4.xlarge instances and the single m4.2xlarge instance in account A (purchasing account). All three instances match the attributes (instance family, Region, platform, tenancy). The discount is applied to instances in the purchasing account (account A) first, even though account B (linked account) has two m4.xlarge that also match the Reserved Instances. There is no capacity reservation because the Reserved Instances are regional Reserved Instances.
- The discount of the two c4.xlarge Reserved Instances applies to the two c4.xlarge instances, because they are a smaller instance size than the c4.2xlarge instance. There is no capacity reservation because the Reserved Instances are regional Reserved Instances.

Scenario 4: Zonal Reserved Instances in a linked account

In general, Reserved Instances that are owned by an account are applied first to usage in that account. However, if there are qualifying, unused Reserved Instances for a specific Availability Zone (zonal Reserved Instances) in other accounts in the organization, they are applied to the account before regional Reserved Instances owned by the account. This is done to ensure maximum Reserved Instance utilization and a lower bill. For billing purposes, all the accounts in the organization are treated as one account. The following example might help explain this.

You're running the following On-Demand Instance in account A (the purchasing account):

- 1 x m4.xlarge Linux, default tenancy instance in Availability Zone us-east-1a

A customer is running the following On-Demand Instance in linked account B:

- 1 x m4.xlarge Linux, default tenancy instance in Availability Zone us-east-1b

You purchase the following regional Reserved Instances in account A:

- 1 x m4.xlarge Linux, default tenancy Reserved Instance in Region us-east-1

A customer also purchases the following zonal Reserved Instances in linked account C:

- 1 x m4.xlarge Linux, default tenancy Reserved Instances in Availability Zone us-east-1a

The Reserved Instance benefits are applied in the following way:

- The discount of the m4.xlarge zonal Reserved Instance owned by account C is applied to the m4.xlarge usage in account A.
- The discount of the m4.xlarge regional Reserved Instance owned by account A is applied to the m4.xlarge usage in account B.
- If the regional Reserved Instance owned by account A was first applied to the usage in account A, the zonal Reserved Instance owned by account C remains unused and usage in account B is charged at On-Demand rates.

For more information, see [Reserved Instances in the Billing and Cost Management Report](#).

Note

Zonal Reserved Instances reserve capacity only for the owning account and cannot be shared with other AWS accounts. If you need to share capacity with other AWS accounts, use [On-Demand Capacity Reservations \(p. 504\)](#).

Use your Reserved Instances

Reserved Instances are automatically applied to running On-Demand Instances provided that the specifications match. If you have no running On-Demand Instances that match the specifications of your Reserved Instance, the Reserved Instance is unused until you launch an instance with the required specifications.

If you're launching an On-Demand Instance to take advantage of the billing benefit of a Reserved Instance, ensure that you specify the following information when you configure your On-Demand Instance:

Platform

You must specify an Amazon Machine Image (AMI) that matches the platform (product description) of your Reserved Instance. For example, if you specified Linux/UNIX for your Reserved Instance, you can launch an instance from an Amazon Linux AMI or an Ubuntu AMI.

Instance type

If you purchased a zonal Reserved Instance, you must specify the same instance type as your Reserved Instance; for example, t3.large. For more information, see [How zonal Reserved Instances are applied \(p. 357\)](#).

If you purchased a regional Reserved Instance, you must specify an instance type from the same instance family as the instance type of your Reserved Instance. For example, if you specified t3.xlarge for your Reserved Instance, you must launch your instance from the T3 family, but you can specify any size, for example, t3.medium. For more information, see [How regional Reserved Instances are applied \(p. 357\)](#).

Availability Zone

If you purchased a zonal Reserved Instance for a specific Availability Zone, you must launch the instance into the same Availability Zone.

If you purchased a regional Reserved Instance, you can launch the instance into any Availability Zone in the Region that you specified for the Reserved Instance.

Tenancy

The tenancy (dedicated or shared) of the instance must match the tenancy of your Reserved Instance. For more information, see [Dedicated Instances \(p. 499\)](#).

For examples of how Reserved Instances are applied to your running On-Demand Instances, see [How Reserved Instances are applied \(p. 357\)](#). For more information, see [Why aren't my Amazon EC2 Reserved Instances applying to my AWS billing in the way that I expected?](#)

You can use various methods to launch the On-Demand Instances that use your Reserved Instance discount. For information about the different launch methods, see [Launch your instance \(p. 551\)](#). You can also use Amazon EC2 Auto Scaling to launch an instance. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).

How you are billed

All Reserved Instances provide you with a discount compared to On-Demand pricing. With Reserved Instances, you pay for the entire term regardless of actual use. You can choose to pay for your Reserved Instance upfront, partially upfront, or monthly, depending on the [payment option \(p. 355\)](#) specified for the Reserved Instance.

When Reserved Instances expire, you are charged On-Demand rates for EC2 instance usage. You can queue a Reserved Instance for purchase up to three years in advance. This can help you ensure that you have uninterrupted coverage. For more information, see [Queue your purchase \(p. 370\)](#).

The AWS Free Tier is available for new AWS accounts. If you are using the AWS Free Tier to run Amazon EC2 instances, and you purchase a Reserved Instance, you are charged under standard pricing guidelines. For information, see [AWS Free Tier](#).

Contents

- [Usage billing \(p. 365\)](#)
- [Viewing your bill \(p. 366\)](#)
- [Reserved Instances and consolidated billing \(p. 366\)](#)
- [Reserved Instance discount pricing tiers \(p. 366\)](#)

Usage billing

Reserved Instances are billed for every clock-hour during the term that you select, regardless of whether an instance is running. Each clock-hour starts on the hour (zero minutes and zero seconds past the hour) of a standard 24-hour clock. For example, 1:00:00 to 1:59:59 is one clock-hour. For more information about instance states, see [Instance lifecycle \(p. 546\)](#).

A Reserved Instance billing benefit can be applied to a running instance on a per-second basis.

A Reserved Instance billing benefit can apply to a maximum of 3600 seconds (one hour) of instance usage per clock-hour. You can run multiple instances concurrently, but can only receive the benefit of the Reserved Instance discount for a total of 3600 seconds per clock-hour; instance usage that exceeds 3600 seconds in a clock-hour is billed at the On-Demand rate.

For example, if you purchase one m4.xlarge Reserved Instance and run four m4.xlarge instances concurrently for one hour, one instance is charged at one hour of Reserved Instance usage and the other three instances are charged at three hours of On-Demand usage.

However, if you purchase one m4.xlarge Reserved Instance and run four m4.xlarge instances for 15 minutes (900 seconds) each within the same hour, the total running time for the instances is one hour, which results in one hour of Reserved Instance usage and 0 hours of On-Demand usage.

	1:00	1:15	1:30	1:45
Instance 1	Orange			
Instance 2		Orange		
Instance 3			Orange	
Instance 4				Orange

If multiple eligible instances are running concurrently, the Reserved Instance billing benefit is applied to all the instances at the same time up to a maximum of 3600 seconds in a clock-hour; thereafter, On-Demand rates apply.

Uses Reserved Instance Rate
for first 3600 seconds of use

Uses
On-Demand Rate

Cost Explorer on the [Billing and Cost Management](#) console enables you to analyze the savings against running On-Demand instances. The [Reserved Instances FAQ](#) includes an example of a list value calculation.

If you close your AWS account, On-Demand billing for your resources stops. However, if you have any Reserved Instances in your account, you continue to receive a bill for these until they expire.

Viewing your bill

You can find out about the charges and fees to your account by viewing the [AWS Billing and Cost Management](#) console.

- The **Dashboard** displays a spend summary for your account.
- On the **Bills** page, under **Details** expand the **Elastic Compute Cloud** section and the Region to get billing information about your Reserved Instances.

You can view the charges online, or you can download a CSV file.

You can also track your Reserved Instance utilization using the AWS Cost and Usage Report. For more information, see [Reserved Instances](#) under Cost and Usage Report in the *AWS Billing User Guide*.

Reserved Instances and consolidated billing

The pricing benefits of Reserved Instances are shared when the purchasing account is part of a set of accounts billed under one consolidated billing payer account. The instance usage across all member accounts is aggregated in the payer account every month. This is typically useful for companies in which there are different functional teams or groups; then, the normal Reserved Instance logic is applied to calculate the bill. For more information, see [Consolidated billing for AWS Organizations](#).

If you close the account that purchased the Reserved Instance, the payer account is charged for the Reserved Instance until the Reserved Instance expires. After the closed account is permanently deleted in 90 days, the member accounts no longer benefit from the Reserved Instance billing discount.

Note

Zonal Reserved Instances reserve capacity only for the owning account and cannot be shared with other AWS accounts. If you need to share capacity with other AWS accounts, use [On-Demand Capacity Reservations](#) (p. 504).

Reserved Instance discount pricing tiers

If your account qualifies for a discount pricing tier, it automatically receives discounts on upfront and instance usage fees for Reserved Instance purchases that you make within that tier level from that point on. To qualify for a discount, the list value of your Reserved Instances in the Region must be \$500,000 USD or more.

The following rules apply:

- Pricing tiers and related discounts apply only to purchases of Amazon EC2 Standard Reserved Instances.
- Pricing tiers do not apply to Reserved Instances for Windows with SQL Server Standard, SQL Server Web, and SQL Server Enterprise.
- Pricing tiers do not apply to Reserved Instances for Linux with SQL Server Standard, SQL Server Web, and SQL Server Enterprise.
- Pricing tier discounts only apply to purchases made from AWS. They do not apply to purchases of third-party Reserved Instances.
- Discount pricing tiers are currently not applicable to Convertible Reserved Instance purchases.

Topics

- [Calculate Reserved Instance pricing discounts \(p. 367\)](#)
- [Buy with a discount tier \(p. 367\)](#)
- [Crossing pricing tiers \(p. 368\)](#)
- [Consolidated billing for pricing tiers \(p. 368\)](#)

Calculate Reserved Instance pricing discounts

You can determine the pricing tier for your account by calculating the list value for all of your Reserved Instances in a Region. Multiply the hourly recurring price for each reservation by the total number of hours for the term and add the undiscounted upfront price (also known as the fixed price) at the time of purchase. Because the list value is based on undiscounted (public) pricing, it is not affected if you qualify for a volume discount or if the price drops after you buy your Reserved Instances.

List value = fixed price + (undiscounted recurring hourly price * hours in term)

For example, for a 1-year Partial Upfront t2.small Reserved Instance, assume the upfront price is \$60.00 and the hourly rate is \$0.007. This provides a list value of \$121.32.

121.32 = 60.00 + (0.007 * 8760)

New console

To view the fixed price values for Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. To display the **Upfront price** column, choose the settings icon () in the top-right corner, toggle on **Upfront price**, and choose **Confirm**.

Old console

To view the fixed price values for Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. To display the **Upfront Price** column, choose the settings icon () in the top-right corner, select **Upfront Price**, and choose **Close**.

To view the fixed price values for Reserved Instances using the command line

- [describe-reserved-instances](#) (AWS CLI)
- [Get-EC2ReservedInstance](#) (AWS Tools for Windows PowerShell)
- [DescribeReservedInstances](#) (Amazon EC2 API)

Buy with a discount tier

When you buy Reserved Instances, Amazon EC2 automatically applies any discounts to the part of your purchase that falls within a discount pricing tier. You don't need to do anything differently, and you can

buy Reserved Instances using any of the Amazon EC2 tools. For more information, see [Buy Reserved Instances \(p. 368\)](#).

After the list value of your active Reserved Instances in a Region crosses into a discount pricing tier, any future purchase of Reserved Instances in that Region are charged at a discounted rate. If a single purchase of Reserved Instances in a Region takes you over the threshold of a discount tier, then the portion of the purchase that is above the price threshold is charged at the discounted rate. For more information about the temporary Reserved Instance IDs that are created during the purchase process, see [Crossing pricing tiers \(p. 368\)](#).

If your list value falls below the price point for that discount pricing tier—for example, if some of your Reserved Instances expire—future purchases of Reserved Instances in the Region are not discounted. However, you continue to get the discount applied against any Reserved Instances that were originally purchased within the discount pricing tier.

When you buy Reserved Instances, one of four possible scenarios occurs:

- **No discount**—Your purchase within a Region is still below the discount threshold.
- **Partial discount**—Your purchase within a Region crosses the threshold of the first discount tier. No discount is applied to one or more reservations and the discounted rate is applied to the remaining reservations.
- **Full discount**—Your entire purchase within a Region falls within one discount tier and is discounted appropriately.
- **Two discount rates**—Your purchase within a Region crosses from a lower discount tier to a higher discount tier. You are charged two different rates: one or more reservations at the lower discounted rate, and the remaining reservations at the higher discounted rate.

Crossing pricing tiers

If your purchase crosses into a discounted pricing tier, you see multiple entries for that purchase: one for that part of the purchase charged at the regular price, and another for that part of the purchase charged at the applicable discounted rate.

The Reserved Instance service generates several Reserved Instance IDs because your purchase crossed from an undiscounted tier, or from one discounted tier to another. There is an ID for each set of reservations in a tier. Consequently, the ID returned by your purchase CLI command or API action is different from the actual ID of the new Reserved Instances.

Consolidated billing for pricing tiers

A consolidated billing account aggregates the list value of member accounts within a Region. When the list value of all active Reserved Instances for the consolidated billing account reaches a discount pricing tier, any Reserved Instances purchased after this point by any member of the consolidated billing account are charged at the discounted rate (as long as the list value for that consolidated account stays above the discount pricing tier threshold). For more information, see [Reserved Instances and consolidated billing \(p. 366\)](#).

Buy Reserved Instances

To purchase a Reserved Instance, search for *Reserved Instance offerings* from AWS and third-party sellers, adjusting your search parameters until you find the exact match that you're looking for.

When you search for Reserved Instances to buy, you receive a quote on the cost of the returned offerings. When you proceed with the purchase, AWS automatically places a limit price on the purchase price. The total cost of your Reserved Instances won't exceed the amount that you were quoted.

If the price rises or changes for any reason, the purchase is not completed. If, at the time of purchase, there are offerings similar to your choice but at a lower price, AWS sells you the offerings at the lower price.

Before you confirm your purchase, review the details of the Reserved Instance that you plan to buy, and make sure that all the parameters are accurate. After you purchase a Reserved Instance (either from a third-party seller in the Reserved Instance Marketplace or from AWS), you cannot cancel your purchase.

Note

To purchase and modify Reserved Instances, ensure that your user has the appropriate permissions, such as the ability to describe Availability Zones. For information, see [Example Policies for Working With the AWS CLI or an AWS SDK](#) and [Example Policies for Working in the Amazon EC2 Console](#).

Topics

- [Choosing a platform \(p. 369\)](#)
- [Queue your purchase \(p. 370\)](#)
- [Buy Standard Reserved Instances \(p. 370\)](#)
- [Buy Convertible Reserved Instances \(p. 372\)](#)
- [Buy from the Reserved Instance Marketplace \(p. 375\)](#)
- [View your Reserved Instances \(p. 375\)](#)
- [Cancel a queued purchase \(p. 376\)](#)
- [Renew a Reserved Instance \(p. 376\)](#)

Choosing a platform

Amazon EC2 supports the following Windows platforms for Reserved Instances:

- Windows
- Windows with SQL Server Standard
- Windows with SQL Server Web
- Windows with SQL Server Enterprise

When you purchase a Reserved Instance, you must choose an offering for a *platform* that represents the operating system for your instance.

- For Windows with SQL Standard, Windows with SQL Server Enterprise, and Windows with SQL Server Web, you must choose offerings for those specific platforms.
- For all other Windows versions, choose an offering for the **Windows** platform.

Note

Ubuntu Pro is not available as a Reserved Instance. For significant savings compared to On-Demand Instance pricing, we recommend that you use Ubuntu Pro with Savings Plans. For more information, see the [Savings Plans User Guide](#).

Important

If you plan to purchase a Reserved Instance to apply to an On-Demand Instance that was launched from an AWS Marketplace AMI, first check the `PlatformDetails` field of the AMI. The `PlatformDetails` field indicates which Reserved Instance to purchase. The platform details of the AMI must match the platform of the Reserved Instance, otherwise the Reserved Instance will not be applied to the On-Demand Instance. For information about how to view the platform details of the AMI, see [Understand AMI billing information \(p. 201\)](#).

For information about the supported platforms for Linux, see [Choosing a platform in the Amazon EC2 User Guide for Linux Instances](#).

Queue your purchase

By default, when you purchase a Reserved Instance, the purchase is made immediately. Alternatively, you can queue your purchases for a future date and time. For example, you can queue a purchase for around the time that an existing Reserved Instance expires. This can help you ensure that you have uninterrupted coverage.

You can queue purchases for regional Reserved Instances, but not zonal Reserved Instances or Reserved Instances from other sellers. You can queue a purchase up to three years in advance. On the scheduled date and time, the purchase is made using the default payment method. After the payment is successful, the billing benefit is applied.

You can view your queued purchases in the Amazon EC2 console. The status of a queued purchase is **queued**. You can cancel a queued purchase any time before its scheduled time. For details, see [Cancel a queued purchase \(p. 376\)](#).

Buy Standard Reserved Instances

You can buy Standard Reserved Instances in a specific Availability Zone and get a capacity reservation. Alternatively, you can forego the capacity reservation and purchase a regional Standard Reserved Instance.

New console

To buy Standard Reserved Instances using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering class**, choose **Standard** to display Standard Reserved Instances.
4. To purchase a capacity reservation, toggle on **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. When you toggle on this setting, the **Availability Zone** field appears.

To purchase a regional Reserved Instance, toggle off this setting. When you toggle off this setting, the **Availability Zone** field disappears.

5. Select other configurations as needed, and then choose **Search**.
6. For each Reserved Instance that you want to purchase, enter the desired quantity, and choose **Add to cart**.

To purchase a Standard Reserved Instance from the Reserved Instance Marketplace, look for **3rd party** in the **Seller** column in the search results. The **Term** column displays non-standard terms. For more information, see [Buy from the Reserved Instance Marketplace \(p. 375\)](#).

7. To see a summary of the Reserved Instances that you selected, choose **View cart**.
8. If **Order on** is **Now**, the purchase is completed immediately after you choose **Order all**. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order all**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from Payment-pending to Active. When the Reserved Instance is Active, it is ready to use.

Note

If the status goes to Retired, AWS might not have received your payment.

Old console

To buy Standard Reserved Instances using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering Class**, choose **Standard** to display Standard Reserved Instances.
4. To purchase a capacity reservation, choose **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. To purchase a regional Reserved Instance, leave the check box unselected.
5. Select other configurations as needed and choose **Search**.

To purchase a Standard Reserved Instance from the Reserved Instance Marketplace, look for **3rd Party** in the **Seller** column in the search results. The **Term** column displays non-standard terms.

6. For each Reserved Instance that you want to purchase, enter the quantity, and choose **Add to Cart**.
7. To see a summary of the Reserved Instances that you selected, choose **View Cart**.
8. If **Order On** is **Now**, the purchase is completed immediately. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from payment-pending to active. When the Reserved Instance is active, it is ready to use.

Note

If the status goes to retired, AWS might not have received your payment.

To buy a Standard Reserved Instance using the AWS CLI

1. Find available Reserved Instances using the [describe-reserved-instances-offerings](#) command. Specify **standard** for the **--offering-class** parameter to return only Standard Reserved Instances. You can apply additional parameters to narrow your results. For example, if you want to purchase a regional t2.large Reserved Instance with a default tenancy for Linux/UNIX for a 1-year term only:

```
aws ec2 describe-reserved-instances-offerings \
--instance-type t2.large \
--offering-class standard \
--product-description "Linux/UNIX" \
```

```
--instance-tenancy default \
--filters Name=duration,Values=31536000 Name=scope,Values=Region
```

To find Reserved Instances on the Reserved Instance Marketplace only, use the `marketplace` filter and do not specify a duration in the request, as the term might be shorter than a 1- or 3-year term.

```
aws ec2 describe-reserved-instances-offerings \
--instance-type t2.large \
--offering-class standard \
--product-description "Linux/UNIX" \
--instance-tenancy default \
--filters Name=marketplace,Values=true
```

When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

```
"ReservedInstancesOfferingId": "bec624df-a8cc-4aad-a72f-4f8abc34caf2"
```

2. Use the [purchase-reserved-instances-offering](#) command to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.

```
aws ec2 purchase-reserved-instances-offering \
--reserved-instances-offering-id bec624df-a8cc-4aad-a72f-4f8abc34caf2 \
--instance-count 1
```

By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following parameter to the previous call.

```
--purchase-time "2020-12-01T00:00:00Z"
```

3. Use the [describe-reserved-instances](#) command to get the status of your Reserved Instance.

```
aws ec2 describe-reserved-instances
```

Alternatively, use the following AWS Tools for Windows PowerShell commands:

- [Get-EC2ReservedInstancesOffering](#)
- [New-EC2ReservedInstance](#)
- [Get-EC2ReservedInstance](#)

After the purchase is complete, if you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not have to restart your instances. If you do not have a suitable running instance, launch an instance and ensure that you match the same criteria that you specified for your Reserved Instance. For more information, see [Use your Reserved Instances \(p. 363\)](#).

For examples of how Reserved Instances are applied to your running instances, see [How Reserved Instances are applied \(p. 357\)](#).

Buy Convertible Reserved Instances

You can buy Convertible Reserved Instances in a specific Availability Zone and get a capacity reservation. Alternatively, you can forego the capacity reservation and purchase a regional Convertible Reserved Instance.

New console

To buy Convertible Reserved Instances using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
 2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
 3. For **Offering class**, choose **Convertible** to display Convertible Reserved Instances.
 4. To purchase a capacity reservation, toggle on **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. When you toggle on this setting, the **Availability Zone** field appears.
- To purchase a regional Reserved Instance, toggle off this setting. When you toggle off this setting, the **Availability Zone** field disappears.
5. Select other configurations as needed and choose **Search**.
 6. For each Convertible Reserved Instance that you want to purchase, enter the quantity, and choose **Add to cart**.
 7. To see a summary of your selection, choose **View cart**.
 8. If **Order on** is **Now**, the purchase is completed immediately after you choose **Order all**. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
 9. To complete the order, choose **Order all**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from **Payment-pending** to **Active**. When the Reserved Instance is **Active**, it is ready to use.

Note

If the status goes to **Retired**, AWS might not have received your payment.

Old console

To buy Convertible Reserved Instances using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering Class**, choose **Convertible** to display Convertible Reserved Instances.
4. To purchase a capacity reservation, choose **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. To purchase a regional Reserved Instance, leave the check box unselected.
5. Select other configurations as needed and choose **Search**.
6. For each Convertible Reserved Instance that you want to purchase, enter the quantity, and choose **Add to Cart**.
7. To see a summary of your selection, choose **View Cart**.
8. If **Order On** is **Now**, the purchase is completed immediately. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from payment-pending to active. When the Reserved Instance is active, it is ready to use.

Note

If the status goes to *retired*, AWS might not have received your payment.

To buy a Convertible Reserved Instance using the AWS CLI

1. Find available Reserved Instances using the [describe-reserved-instances-offerings](#) command. Specify convertible for the --offering-class parameter to return only Convertible Reserved Instances. You can apply additional parameters to narrow your results; for example, if you want to purchase a regional t2.large Reserved Instance with a default tenancy for Linux/UNIX:

```
aws ec2 describe-reserved-instances-offerings \
--instance-type t2.large \
--offering-class convertible \
--product-description "Linux/UNIX" \
--instance-tenancy default \
--filters Name=scope,Values=Region
```

When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

```
"ReservedInstancesOfferingId": "bec624df-a8cc-4aad-a72f-4f8abc34caf2"
```

2. Use the [purchase-reserved-instances-offering](#) command to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.

```
aws ec2 purchase-reserved-instances-offering \
--reserved-instances-offering-id bec624df-a8cc-4aad-a72f-4f8abc34caf2 \
--instance-count 1
```

By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following parameter to the previous call.

```
--purchase-time "2020-12-01T00:00:00Z"
```

3. Use the [describe-reserved-instances](#) command to get the status of your Reserved Instance.

```
aws ec2 describe-reserved-instances
```

Alternatively, use the following AWS Tools for Windows PowerShell commands:

- [Get-EC2ReservedInstancesOffering](#)
- [New-EC2ReservedInstance](#)
- [Get-EC2ReservedInstance](#)

If you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not have to restart your instances. If you do not have a suitable running instance, launch an instance and ensure that you match the same criteria that you specified for your Reserved Instance. For more information, see [Use your Reserved Instances \(p. 363\)](#).

For examples of how Reserved Instances are applied to your running instances, see [How Reserved Instances are applied \(p. 357\)](#).

Buy from the Reserved Instance Marketplace

You can purchase Reserved Instances from third-party sellers who own Reserved Instances that they no longer need from the Reserved Instance Marketplace. You can do this using the Amazon EC2 console or a command line tool. The process is similar to purchasing Reserved Instances from AWS. For more information, see [Buy Standard Reserved Instances \(p. 370\)](#).

There are a few differences between Reserved Instances purchased in the Reserved Instance Marketplace and Reserved Instances purchased directly from AWS:

- **Term** – Reserved Instances that you purchase from third-party sellers have less than a full standard term remaining. Full standard terms from AWS run for one year or three years.
- **Upfront price** – Third-party Reserved Instances can be sold at different upfront prices. The usage or recurring fees remain the same as the fees set when the Reserved Instances were originally purchased from AWS.
- **Types of Reserved Instances** – Only Amazon EC2 Standard Reserved Instances can be purchased from the Reserved Instance Marketplace. Convertible Reserved Instances, Amazon RDS, and Amazon ElastiCache Reserved Instances are not available for purchase on the Reserved Instance Marketplace.

Basic information about you is shared with the seller, for example, your ZIP code and country information.

This information enables sellers to calculate any necessary transaction taxes that they have to remit to the government (such as sales tax or value-added tax) and is provided as a disbursement report. In rare circumstances, AWS might have to provide the seller with your email address, so that they can contact you regarding questions related to the sale (for example, tax questions).

For similar reasons, AWS shares the legal entity name of the seller on the buyer's purchase invoice. If you need additional information about the seller for tax or related reasons, contact [AWS Support](#).

View your Reserved Instances

You can view the Reserved Instances you've purchased using the Amazon EC2 console, or a command line tool.

To view your Reserved Instances in the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Your queued, active, and retired Reserved Instances are listed. The **State** column displays the state.
4. If you are a seller in the Reserved Instance Marketplace, the **My Listings** tab displays the status of a reservation that's listed in the [Reserved Instance Marketplace \(p. 377\)](#). For more information, see [Reserved Instance listing states \(p. 381\)](#).

To view your Reserved Instances using the command line

- [describe-reserved-instances](#) (AWS CLI)
- [Get-EC2ReservedInstance](#) (Tools for Windows PowerShell)

Cancel a queued purchase

You can queue a purchase up to three years in advance. You can cancel a queued purchase any time before its scheduled time.

New console

To cancel a queued purchase

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select one or more Reserved Instances.
4. Choose **Actions, Delete queued Reserved Instances**.
5. When prompted for confirmation, choose **Delete**, and then **Close**.

Old console

To cancel a queued purchase

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select one or more Reserved Instances.
4. Choose **Actions, Delete Queued Reserved Instances**.
5. When prompted for confirmation, choose **Yes, Delete**.

To cancel a queued purchase using the command line

- [delete-queued-reserved-instances](#) (AWS CLI)
- [Remove-EC2QueuedReservedInstance](#) (Tools for Windows PowerShell)

Renew a Reserved Instance

You can renew a Reserved Instance before it is scheduled to expire. Renewing a Reserved Instance queues the purchase of a Reserved Instance with the same configuration until the current Reserved Instance expires.

New console

To renew a Reserved Instance using a queued purchase

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instance to renew.
4. Choose **Actions, Renew Reserved Instances**.
5. To complete the order, choose **Order all**, and then **Close**.

Old console

To renew a Reserved Instance using a queued purchase

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.

3. Select the Reserved Instance to renew.
4. Choose **Actions, Renew Reserved Instances**.
5. To complete the order, choose **Order**.

Sell in the Reserved Instance Marketplace

The Reserved Instance Marketplace is a platform that supports the sale of third-party and AWS customers' unused Standard Reserved Instances, which vary in term lengths and pricing options. For example, you might want to sell Reserved Instances after moving instances to a new AWS Region, changing to a new instance type, ending projects before the term expiration, when your business needs change, or if you have unneeded capacity.

As soon as you list your Reserved Instances in the Reserved Instance Marketplace, they are available for potential buyers to find. All Reserved Instances are grouped according to the duration of the term remaining and the hourly price.

To fulfill a buyer's request, AWS first sells the Reserved Instance with the lowest upfront price in the specified grouping. Then, AWS sells the Reserved Instance with the next lowest price, until the buyer's entire order is fulfilled. AWS then processes the transactions and transfers ownership of the Reserved Instances to the buyer.

You own your Reserved Instance until it's sold. After the sale, you've given up the capacity reservation and the discounted recurring fees. If you continue to use your instance, AWS charges you the On-Demand price starting from the time that your Reserved Instance was sold.

If you want to sell your unused Reserved Instances on the Reserved Instance Marketplace, you must meet certain eligibility criteria.

For information about buying Reserved Instances on the Reserved Instance Marketplace, see [Buy from the Reserved Instance Marketplace \(p. 375\)](#).

Contents

- [Restrictions and limitations \(p. 377\)](#)
- [Register as a seller \(p. 378\)](#)
- [Bank account for disbursement \(p. 378\)](#)
- [Tax information \(p. 379\)](#)
- [Price your Reserved Instances \(p. 379\)](#)
- [List your Reserved Instances \(p. 380\)](#)
- [Reserved Instance listing states \(p. 381\)](#)
- [Lifecycle of a listing \(p. 381\)](#)
- [After your Reserved Instance is sold \(p. 382\)](#)
- [Getting paid \(p. 382\)](#)
- [Information shared with the buyer \(p. 383\)](#)

Restrictions and limitations

Before you can sell your unused reservations, you must register as a seller in the Reserved Instance Marketplace. For information, see [Register as a seller \(p. 378\)](#).

The following limitations and restrictions apply when selling Reserved Instances:

- Only Amazon EC2 Standard regional and zonal Reserved Instances can be sold in the Reserved Instance Marketplace.

- Amazon EC2 Convertible Reserved Instances cannot be sold in the Reserved Instance Marketplace.
- Reserved Instances for other AWS services, such as Amazon RDS and Amazon ElastiCache, cannot be sold in the Reserved Instance Marketplace.
- There must be at least one month remaining in the term of the Standard Reserved Instance.
- You cannot sell a Standard Reserved Instance in a Region that is [disabled by default](#).
- The minimum price allowed in the Reserved Instance Marketplace is \$0.00.
- You can sell No Upfront, Partial Upfront, or All Upfront Reserved Instances in the Reserved Instance Marketplace as long as they have been active in your account for at least 30 days. Additionally, if there is an upfront payment on a Reserved Instance, it can only be sold after AWS has received the upfront payment.
- You cannot modify your listing in the Reserved Instance Marketplace directly. However, you can change your listing by first canceling it and then creating another listing with new parameters. For information, see [Price your Reserved Instances \(p. 379\)](#). You can also modify your Reserved Instances before listing them. For information, see [Modify Reserved Instances \(p. 383\)](#).
- AWS charges a service fee of 12 percent of the total upfront price of each Standard Reserved Instance you sell in the Reserved Instance Marketplace. The upfront price is the price the seller is charging for the Standard Reserved Instance.
- When you register as a seller, the bank you specify must have a US address. For more information, see [Additional seller requirements for paid products](#) in the *AWS Marketplace Seller Guide*.
- Amazon Internet Services Private Limited (AISPL) customers can't sell Reserved Instances in the Reserved Instance Marketplace even if they have a US bank account. For more information, see [What are the differences between AWS accounts and AISPL accounts?](#)

Register as a seller

Note

Only the AWS account root user can register an account as a seller.

To sell in the Reserved Instance Marketplace, you must first register as a seller. During registration, you provide the following information:

- **Bank information**—AWS must have your bank information in order to disburse funds collected when you sell your reservations. The bank you specify must have a US address. For more information, see [Bank account for disbursement \(p. 378\)](#).
- **Tax information**—All sellers are required to complete a tax information interview to determine any necessary tax reporting obligations. For more information, see [Tax information \(p. 379\)](#).

After AWS receives your completed seller registration, you receive an email confirming your registration and informing you that you can get started selling in the Reserved Instance Marketplace.

Bank account for disbursement

AWS must have your bank information in order to disburse funds collected when you sell your Reserved Instance. The bank you specify must have a US address. For more information, see [Additional seller requirements for paid products](#) in the *AWS Marketplace Seller Guide*.

To register a default bank account for disbursements

1. Open the [Reserved Instance Marketplace Seller Registration](#) page and sign in using your AWS credentials.
2. On the **Manage Bank Account** page, provide the following information about the bank through to receive payment:
 - Bank account holder name

- Routing number
- Account number
- Bank account type

Note

If you are using a corporate bank account, you are prompted to send the information about the bank account via fax (1-206-765-3424).

After registration, the bank account provided is set as the default, pending verification with the bank. It can take up to two weeks to verify a new bank account, during which time you can't receive disbursements. For an established account, it usually takes about two days for disbursements to complete.

To change the default bank account for disbursement

1. On the [Reserved Instance Marketplace Seller Registration](#) page, sign in with the account that you used when you registered.
2. On the **Manage Bank Account** page, add a new bank account or modify the default bank account as needed.

Tax information

Your sale of Reserved Instances might be subject to a transaction-based tax, such as sales tax or value-added tax. You should check with your business's tax, legal, finance, or accounting department to determine if transaction-based taxes are applicable. You are responsible for collecting and sending the transaction-based taxes to the appropriate tax authority.

As part of the seller registration process, you must complete a tax interview in the [Seller Registration Portal](#). The interview collects your tax information and populates an IRS form W-9, W-8BEN, or W-8BEN-E, which is used to determine any necessary tax reporting obligations.

The tax information you enter as part of the tax interview might differ depending on whether you operate as an individual or business, and whether you or your business are a US or non-US person or entity. As you fill out the tax interview, keep in mind the following:

- Information provided by AWS, including the information in this topic, does not constitute tax, legal, or other professional advice. To find out how the IRS reporting requirements might affect your business, or if you have other questions, contact your tax, legal, or other professional advisor.
- To fulfill the IRS reporting requirements as efficiently as possible, answer all questions and enter all information requested during the interview.
- Check your answers. Avoid misspellings or entering incorrect tax identification numbers. They can result in an invalidated tax form.

Based on your tax interview responses and IRS reporting thresholds, Amazon might file Form 1099-K. Amazon mails a copy of your Form 1099-K on or before January 31 in the year following the year that your tax account reaches the threshold levels. For example, if your account reaches the threshold in 2018, your Form 1099-K is mailed on or before January 31, 2019.

For more information about IRS requirements and Form 1099-K, see the [IRS](#) website.

Price your Reserved Instances

When setting the price for your Reserved Instances, consider the following:

- **Upfront price** – The upfront price is the only price that you can specify for the Reserved Instance that you're selling. The upfront price is the one-time price that the buyer pays when they purchase a Reserved Instance.

Because the value of Reserved Instances decreases over time, by default, AWS can set prices to decrease in equal increments month over month. However, you can set different upfront prices based on when your reservation sells. For example, if your Reserved Instance has nine months of its term remaining, you can specify the amount that you would accept if a customer were to purchase that Reserved Instance with nine months remaining. You could set another price with five months remaining, and yet another price with one month remaining.

The minimum allowed price in the Reserved Instance Marketplace is \$0.00.

- **Limits** – The following limits for selling Reserved Instances apply to the *lifetime* of your AWS account. They are not annual limits.
 - **You can sell up to \$50,000 in Reserved Instances.**
 - **You can sell up to 5,000 Reserved Instances.**

These limits typically can't be increased, but will be evaluated on a case-by-case basis if requested. To request a limit increase, complete the [Service limit increase](#) form. For **Limit type**, choose **EC2 Reserved Instance Sales**.

- **Can't modify** – You cannot modify your listing directly. However, you can change your listing by first canceling it and then creating another listing with new parameters.
- **Can cancel** – You can cancel your listing at any time, as long as it's in the active state. You cannot cancel the listing if it's already matched or being processed for a sale. If some of the instances in your listing are matched and you cancel the listing, only the remaining unmatched instances are removed from the listing.

List your Reserved Instances

As a registered seller, you can choose to sell one or more of your Reserved Instances. You can choose to sell all of them in one listing or in portions. In addition, you can list Reserved Instances with any configuration of instance type, platform, and scope.

The console determines a suggested price. It checks for offerings that match your Reserved Instance and matches the one with the lowest price. Otherwise, it calculates a suggested price based on the cost of the Reserved Instance for its remaining time. If the calculated value is less than \$1.01, the suggested price is \$1.01.

If you cancel your listing and a portion of that listing has already been sold, the cancellation is not effective on the portion that has been sold. Only the unsold portion of the listing is no longer available in the Reserved Instance Marketplace.

To list a Reserved Instance in the Reserved Instance Marketplace using the AWS Management Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instances to list, and choose **Actions, Sell Reserved Instances**.
4. On the **Configure Your Reserved Instance Listing** page, set the number of instances to sell and the upfront price for the remaining term in the relevant columns. See how the value of your reservation changes over the remainder of the term by selecting the arrow next to the **Months Remaining** column.
5. If you are an advanced user and you want to customize the pricing, you can enter different values for the subsequent months. To return to the default linear price drop, choose **Reset**.
6. Choose **Continue** when you are finished configuring your listing.

7. Confirm the details of your listing, on the **Confirm Your Reserved Instance Listing** page and if you're satisfied, choose **List Reserved Instance**.

To view your listings in the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select the Reserved Instance that you've listed and choose the **My Listings** tab near the bottom of the page.

To manage Reserved Instances in the Reserved Instance Marketplace using the AWS CLI

1. Get a list of your Reserved Instances by using the [describe-reserved-instances](#) command.
2. Note the ID of the Reserved Instance you want to list and call [create-reserved-instances-listing](#). You must specify the ID of the Reserved Instance, the number of instances, and the pricing schedule.
3. To view your listing, use the [describe-reserved-instances-listings](#) command.
4. To cancel your listing, use the [cancel-reserved-instances-listings](#) command.

Reserved Instance listing states

Listing State on the **My Listings** tab of the Reserved Instances page displays the current status of your listings:

The information displayed by **Listing State** is about the status of your listing in the Reserved Instance Marketplace. It is different from the status information that is displayed by the **State** column in the **Reserved Instances** page. This **State** information is about your reservation.

- **active**—The listing is available for purchase.
- **canceled**—The listing is canceled and isn't available for purchase in the Reserved Instance Marketplace.
- **closed**—The Reserved Instance is not listed. A Reserved Instance might be closed because the sale of the listing was completed.

Lifecycle of a listing

When all the instances in your listing are matched and sold, the **My Listings** tab shows that the **Total instance count** matches the count listed under **Sold**. Also, there are no **Available** instances left for your listing, and its **Status** is **closed**.

When only a portion of your listing is sold, AWS retires the Reserved Instances in the listing and creates the number of Reserved Instances equal to the Reserved Instances remaining in the count. So, the listing ID and the listing that it represents, which now has fewer reservations for sale, is still active.

Any future sales of Reserved Instances in this listing are processed this way. When all the Reserved Instances in the listing are sold, AWS marks the listing as **closed**.

For example, you create a listing *Reserved Instances listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample* with a listing count of 5.

The **My Listings** tab in the **Reserved Instance** console page displays the listing this way:

Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample

- Total reservation count = 5

- Sold = 0
- Available = 5
- Status = active

A buyer purchases two of the reservations, which leaves a count of three reservations still available for sale. Because of this partial sale, AWS creates a new reservation with a count of three to represent the remaining reservations that are still for sale.

This is how your listing looks in the **My Listings** tab:

Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample

- Total reservation count = 5
- Sold = 2
- Available = 3
- Status = active

If you cancel your listing and a portion of that listing has already sold, the cancellation is not effective on the portion that has been sold. Only the unsold portion of the listing is no longer available in the Reserved Instance Marketplace.

After your Reserved Instance is sold

When your Reserved Instance is sold, AWS sends you an email notification. Each day that there is any kind of activity, you receive one email notification capturing all the activities of the day. Activities can include when you create or sell a listing, or when AWS sends funds to your account.

To track the status of a Reserved Instance listing in the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation page, choose **Reserved Instances**.
3. Choose the **My Listings** tab.

The **My Listings** tab contains the **Listing State** value. It also contains information about the term, listing price, and a breakdown of how many instances in the listing are available, pending, sold, and canceled.

You can also use the [describe-reserved-instances-listings](#) command with the appropriate filter to obtain information about your listings.

Getting paid

As soon as AWS receives funds from the buyer, a message is sent to the registered owner account email for the sold Reserved Instance.

AWS sends an Automated Clearing House (ACH) wire transfer to your specified bank account. Typically, this transfer occurs between one to three days after your Reserved Instance has been sold. Disbursements take place once a day. You will receive an email with a disbursement report after the funds are released. Keep in mind that you can't receive disbursements until AWS receives verification from your bank. This can take up to two weeks.

The Reserved Instance that you sold continues to appear when you describe your Reserved Instances.

You receive a cash disbursement for your Reserved Instances through a wire transfer directly into your bank account. AWS charges a service fee of 12 percent of the total upfront price of each Reserved Instance you sell in the Reserved Instance Marketplace.

Information shared with the buyer

When you sell in the Reserved Instance Marketplace, AWS shares your company's legal name on the buyer's statement in accordance with US regulations. In addition, if the buyer calls AWS Support because the buyer needs to contact you for an invoice or for some other tax-related reason, AWS might need to provide the buyer with your email address so that the buyer can contact you directly.

For similar reasons, the buyer's ZIP code and country information are provided to the seller in the disbursement report. As a seller, you might need this information to accompany any necessary transaction taxes that you remit to the government (such as sales tax and value-added tax).

AWS cannot offer tax advice, but if your tax specialist determines that you need specific additional information, [contact AWS Support](#).

Modify Reserved Instances

When your needs change, you can modify your Standard or Convertible Reserved Instances and continue to benefit from the billing benefit. You can modify attributes such as the Availability Zone and scope of your Reserved Instance.

Note

You can also exchange a Convertible Reserved Instance for another Convertible Reserved Instance with a different configuration. For more information, see [Exchange Convertible Reserved Instances \(p. 387\)](#).

After modification, the benefit of the Reserved Instances is applied only to instances that match the new parameters. For example, if you change the Availability Zone of a reservation, the capacity reservation and pricing benefits are automatically applied to instance usage in the new Availability Zone. Instances that no longer match the new parameters are charged at the On-Demand rate, unless your account has other applicable reservations.

If your modification request succeeds:

- The modified reservation becomes effective immediately and the pricing benefit is applied to the new instances beginning at the hour of the modification request. For example, if you successfully modify your reservations at 9:15PM, the pricing benefit transfers to your new instance at 9:00PM. You can get the effective date of the modified Reserved Instances by using the [describe-reserved-instances](#) command.
- The original reservation is retired. Its end date is the start date of the new reservation, and the end date of the new reservation is the same as the end date of the original Reserved Instance. If you modify a three-year reservation that had 16 months left in its term, the resulting modified reservation is a 16-month reservation with the same end date as the original one.
- The modified reservation lists a \$0 fixed price and not the fixed price of the original reservation.
- The fixed price of the modified reservation does not affect the discount pricing tier calculations applied to your account, which are based on the fixed price of the original reservation.

If your modification request fails, your Reserved Instances maintain their original configuration, and are immediately available for another modification request.

There is no fee for modification, and you do not receive any new bills or invoices.

You can modify your reservations as frequently as you like, but you cannot change or cancel a pending modification request after you submit it. After the modification has completed successfully, you can submit another modification request to roll back any changes you made, if needed.

Contents

- [Requirements and restrictions for modification \(p. 384\)](#)
- [Submit modification requests \(p. 385\)](#)
- [Troubleshoot modification requests \(p. 387\)](#)

Requirements and restrictions for modification

You can modify these attributes as follows.

Modifiable attribute	Supported platforms	Limitations and considerations
Change Availability Zones within the same Region	Linux and Windows	-
Change the scope from Availability Zone to Region and vice versa	Linux and Windows	A zonal Reserved Instance is scoped to an Availability Zone and reserves capacity in that Availability Zone. If you change the scope from Availability Zone to Region (in other words, from zonal to regional), you lose the capacity reservation benefit. A regional Reserved Instance is scoped to a Region. Your Reserved Instance discount can apply to instances running in any Availability Zone in that Region. Furthermore, the Reserved Instance discount applies to instance usage across all sizes in the selected instance family. If you change the scope from Region to Availability Zone (in other words, from regional to zonal), you lose Availability Zone flexibility and instance size flexibility (if applicable). For more information, see How Reserved Instances are applied (p. 357) .
Change the instance size within the same instance family and generation	Linux/UNIX only Instance size flexibility is not available for Reserved Instances on the other platforms, which include Linux with SQL Server Standard, Linux with SQL Server Web, Linux with SQL Server Enterprise, Red Hat Enterprise Linux, SUSE Linux, Windows, Windows with SQL Standard, Windows with SQL Server Enterprise, and Windows with SQL Server Web.	The reservation must use default tenancy. Some instance families are not supported, because there are no other sizes available. For more information, see Support for modifying instance sizes in the <i>Amazon EC2 User Guide for Linux Instances</i> .

Requirements

Amazon EC2 processes your modification request if there is sufficient capacity for your new configuration (if applicable), and if the following conditions are met:

- The Reserved Instance cannot be modified before or at the same time that you purchase it
- The Reserved Instance must be active
- There cannot be a pending modification request
- The Reserved Instance is not listed in the Reserved Instance Marketplace
- The original Reserved Instances are all Standard Reserved Instances or all Convertible Reserved Instances, not some of each type
- The original Reserved Instances must expire within the same hour, if they are Standard Reserved Instances
- The Reserved Instance is not a G4 instance.

Submit modification requests

Before you modify your Reserved Instances, ensure that you have read the applicable [restrictions \(p. 384\)](#).

New console

To modify your Reserved Instances using the AWS Management Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the **Reserved Instances** page, select one or more Reserved Instances to modify, and choose **Actions, Modify Reserved Instances**.

Note

If your Reserved Instances are not in the active state or cannot be modified, **Modify Reserved Instances** is disabled.

3. The first entry in the modification table displays attributes of the selected Reserved Instances, and at least one target configuration beneath it. The **Units** column displays the total instance size footprint. Choose **Add** for each new configuration to add. Modify the attributes as needed for each configuration.

- **Scope:** Choose whether the configuration applies to an Availability Zone or to the whole Region.
- **Availability Zone:** Choose the required Availability Zone. Not applicable for regional Reserved Instances.
- **Count:** Specify the number of instances. To split the Reserved Instances into multiple configurations, reduce the count, choose **Add**, and specify a count for the additional configuration. For example, if you have a single configuration with a count of 10, you can change its count to 6 and add a configuration with a count of 4. This process retires the original Reserved Instance after the new Reserved Instances are activated.

4. Choose **Continue**.
5. To confirm your modification choices when you finish specifying your target configurations, choose **Submit modifications**.
6. You can determine the status of your modification request by looking at the **State** column in the Reserved Instances screen. The following are the possible states.
 - **active (pending modification)** — Transition state for original Reserved Instances
 - **retired (pending modification)** — Transition state for original Reserved Instances while new Reserved Instances are being created

- **retired** — Reserved Instances successfully modified and replaced
- **active** — One of the following:
 - New Reserved Instances created from a successful modification request
 - Original Reserved Instances after a failed modification request

Old console

To modify your Reserved Instances using the AWS Management Console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the **Reserved Instances** page, select one or more Reserved Instances to modify, and choose **Actions, Modify Reserved Instances**.

Note

If your Reserved Instances are not in the active state or cannot be modified, **Modify Reserved Instances** is disabled.

3. The first entry in the modification table displays attributes of selected Reserved Instances, and at least one target configuration beneath it. The **Units** column displays the total instance size footprint. Choose **Add** for each new configuration to add. Modify the attributes as needed for each configuration, and then choose **Continue**:
 - **Scope**: Choose whether the configuration applies to an Availability Zone or to the whole Region.
 - **Availability Zone**: Choose the required Availability Zone. Not applicable for regional Reserved Instances.
 - **Count**: Specify the number of instances. To split the Reserved Instances into multiple configurations, reduce the count, choose **Add**, and specify a count for the additional configuration. For example, if you have a single configuration with a count of 10, you can change its count to 6 and add a configuration with a count of 4. This process retires the original Reserved Instance after the new Reserved Instances are activated.
4. To confirm your modification choices when you finish specifying your target configurations, choose **Submit Modifications**.
5. You can determine the status of your modification request by looking at the **State** column in the Reserved Instances screen. The following are the possible states.
 - **active (pending modification)** — Transition state for original Reserved Instances
 - **retired (pending modification)** — Transition state for original Reserved Instances while new Reserved Instances are being created
 - **retired** — Reserved Instances successfully modified and replaced
 - **active** — One of the following:
 - New Reserved Instances created from a successful modification request
 - Original Reserved Instances after a failed modification request

To modify your Reserved Instances using the command line

1. To modify your Reserved Instances, you can use one of the following commands:
 - [modify-reserved-instances](#) (AWS CLI)
 - [Edit-EC2ReservedInstance](#) (AWS Tools for Windows PowerShell)
2. To get the status of your modification request (processing, fulfilled, or failed), use one of the following commands:
 - [describe-reserved-instances-modifications](#) (AWS CLI)
 - [Get-EC2ReservedInstancesModification](#) (AWS Tools for Windows PowerShell)

Troubleshoot modification requests

If the target configuration settings that you requested were unique, you receive a message that your request is being processed. At this point, Amazon EC2 has only determined that the parameters of your modification request are valid. Your modification request can still fail during processing due to unavailable capacity.

In some situations, you might get a message indicating incomplete or failed modification requests instead of a confirmation. Use the information in such messages as a starting point for resubmitting another modification request. Ensure that you have read the applicable [restrictions \(p. 384\)](#) before submitting the request.

Not all selected Reserved Instances can be processed for modification

Amazon EC2 identifies and lists the Reserved Instances that cannot be modified. If you receive a message like this, go to the **Reserved Instances** page in the Amazon EC2 console and check the information for the Reserved Instances.

Error in processing your modification request

You submitted one or more Reserved Instances for modification and none of your requests can be processed. Depending on the number of reservations you are modifying, you can get different versions of the message.

Amazon EC2 displays the reasons why your request cannot be processed. For example, you might have specified the same target configuration—a combination of Availability Zone and platform—for one or more subsets of the Reserved Instances you are modifying. Try submitting the modification requests again, but ensure that the instance details of the reservations match, and that the target configurations for all subsets being modified are unique.

Exchange Convertible Reserved Instances

You can exchange one or more Convertible Reserved Instances for another Convertible Reserved Instance with a different configuration, including instance family, operating system, and tenancy. There are no limits to how many times you perform an exchange, as long as the new Convertible Reserved Instance is of an equal or higher value than the Convertible Reserved Instances that you are exchanging.

When you exchange your Convertible Reserved Instance, the number of instances for your current reservation is exchanged for a number of instances that cover the equal or higher value of the configuration of the new Convertible Reserved Instance. Amazon EC2 calculates the number of Reserved Instances that you can receive as a result of the exchange.

You can't exchange Standard Reserved Instances, but you can modify them. For more information, see [Modify Reserved Instances \(p. 383\)](#).

Contents

- [Requirements for exchanging Convertible Reserved Instances \(p. 387\)](#)
- [Calculate Convertible Reserved Instances exchanges \(p. 389\)](#)
- [Merge Convertible Reserved Instances \(p. 389\)](#)
- [Exchange a portion of a Convertible Reserved Instance \(p. 390\)](#)
- [Submit exchange requests \(p. 390\)](#)

Requirements for exchanging Convertible Reserved Instances

If the following conditions are met, Amazon EC2 processes your exchange request. Your Convertible Reserved Instance must be:

- Active
- Not pending a previous exchange request
- Have at least 24 hours remaining before it expires

The following rules apply:

- Convertible Reserved Instances can only be exchanged for other Convertible Reserved Instances currently offered by AWS.
- Convertible Reserved Instances are associated with a specific Region, which is fixed for the duration of the reservation's term. You cannot exchange a Convertible Reserved Instance for a Convertible Reserved Instance in a different Region.
- You can exchange one or more Convertible Reserved Instances at a time for one Convertible Reserved Instance only.
- To exchange a portion of a Convertible Reserved Instance, you can modify it into two or more reservations, and then exchange one or more of the reservations for a new Convertible Reserved Instance. For more information, see [Exchange a portion of a Convertible Reserved Instance \(p. 390\)](#). For more information about modifying your Reserved Instances, see [Modify Reserved Instances \(p. 383\)](#).
- All Upfront Convertible Reserved Instances can be exchanged for Partial Upfront Convertible Reserved Instances, and vice versa.

Note

If the total upfront payment required for the exchange (true-up cost) is less than \$0.00, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that true-up cost is \$0.00 or more.

Note

If the total value (upfront price + hourly price * number of remaining hours) of the new Convertible Reserved Instance is less than the total value of the exchanged Convertible Reserved Instance, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that the total value is the same or higher than that of the exchanged Convertible Reserved Instance.

- To benefit from better pricing, you can exchange a No Upfront Convertible Reserved Instance for an All Upfront or Partial Upfront Convertible Reserved Instance.
- You cannot exchange All Upfront and Partial Upfront Convertible Reserved Instances for No Upfront Convertible Reserved Instances.
- You can exchange a No Upfront Convertible Reserved Instance for another No Upfront Convertible Reserved Instance only if the new Convertible Reserved Instance's hourly price is the same or higher than the exchanged Convertible Reserved Instance's hourly price.

Note

If the total value (hourly price * number of remaining hours) of the new Convertible Reserved Instance is less than the total value of the exchanged Convertible Reserved Instance, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that the total value is the same or higher than that of the exchanged Convertible Reserved Instance.

- If you exchange multiple Convertible Reserved Instances that have different expiration dates, the expiration date for the new Convertible Reserved Instance is the date that's furthest in the future.
- If you exchange a single Convertible Reserved Instance, it must have the same term (1-year or 3-years) as the new Convertible Reserved Instance. If you merge multiple Convertible Reserved Instances with different term lengths, the new Convertible Reserved Instance has a 3-year term. For more information, see [Merge Convertible Reserved Instances \(p. 389\)](#).
- When Amazon EC2 exchanges a Convertible Reserved Instance, it retires the associated reservation, and transfers the end date to the new reservation. After the exchange, Amazon EC2 sets both the end date for the old reservation and the start date for the new reservation equal to the date of the

exchange. For example, if you exchange a three-year reservation that had 16 months left in its term, the new reservation is a 16-month reservation with the same end date as the reservation from the Convertible Reserved Instance that you exchanged.

Calculate Convertible Reserved Instances exchanges

Exchanging Convertible Reserved Instances is free. However, you might be required to pay a true-up cost, which is a prorated upfront cost of the difference between the original Convertible Reserved Instances that you had and the new Convertible Reserved Instances that you receive from the exchange.

Each Convertible Reserved Instance has a list value. This list value is compared to the list value of the Convertible Reserved Instances that you want in order to determine how many instance reservations you can receive from the exchange.

For example: You have 1 x \$35-list value Convertible Reserved Instance that you want to exchange for a new instance type with a list value of \$10.

\$35/\$10 = 3.5

You can exchange your Convertible Reserved Instance for three \$10 Convertible Reserved Instances. It's not possible to purchase half reservations; therefore you must purchase an additional Convertible Reserved Instance to cover the remainder:

3.5 = 3 whole Convertible Reserved Instances + 1 additional Convertible Reserved Instance

The fourth Convertible Reserved Instance has the same end date as the other three. If you are exchanging Partial or All Upfront Convertible Reserved Instances, you pay the true-up cost for the fourth reservation. If the remaining upfront cost of your Convertible Reserved Instances is \$500, and the new reservation would normally cost \$600 on a prorated basis, you are charged \$100.

\$600 prorated upfront cost of new reservations - \$500 remaining upfront cost of original reservations = \$100 difference

Merge Convertible Reserved Instances

If you merge two or more Convertible Reserved Instances, the term of the new Convertible Reserved Instance must be the same as the original Convertible Reserved Instances, or the highest of the original Convertible Reserved Instances. The expiration date for the new Convertible Reserved Instance is the expiration date that's furthest in the future.

For example, you have the following Convertible Reserved Instances in your account:

Reserved Instance ID	Term	Expiration date
aaaa1111	1-year	2018-12-31
bbbb2222	1-year	2018-07-31
cccc3333	3-year	2018-06-30
dddd4444	3-year	2019-12-31

- You can merge aaaa1111 and bbbb2222 and exchange them for a 1-year Convertible Reserved Instance. You cannot exchange them for a 3-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2018-12-31.

- You can merge bbbb2222 and cccc3333 and exchange them for a 3-year Convertible Reserved Instance. You cannot exchange them for a 1-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2018-07-31.
- You can merge cccc3333 and dddd4444 and exchange them for a 3-year Convertible Reserved Instance. You cannot exchange them for a 1-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2019-12-31.

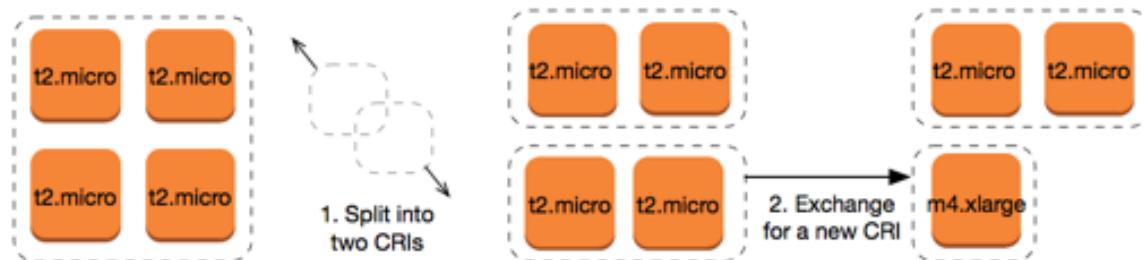

Exchange a portion of a Convertible Reserved Instance

You can use the modification process to split your Convertible Reserved Instance into smaller reservations, and then exchange one or more of the new reservations for a new Convertible Reserved Instance. The following examples demonstrate how you can do this.

Example Example: Convertible Reserved Instance with multiple instances

In this example, you have a t2.micro Convertible Reserved Instance with four instances in the reservation. To exchange two t2.micro instances for an m4.xlarge instance:

1. Modify the t2.micro Convertible Reserved Instance by splitting it into two t2.micro Convertible Reserved Instances with two instances each.
2. Exchange one of the new t2.micro Convertible Reserved Instances for an m4.xlarge Convertible Reserved Instance.

Submit exchange requests

You can exchange your Convertible Reserved Instances using the Amazon EC2 console or a command line tool.

Exchange a Convertible Reserved Instance using the console

You can search for Convertible Reserved Instances offerings and select your new configuration from the choices provided.

New console

To exchange Convertible Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Reserved Instances**, select the Convertible Reserved Instances to exchange, and choose **Actions, Exchange Reserved Instance**.
3. Select the attributes of the desired configuration, and choose **Find offering**.
4. Select a new Convertible Reserved Instance. At the bottom of the screen, you can view the number of Reserved Instances that you receive for the exchange, and any additional costs.
5. When you have selected a Convertible Reserved Instance that meets your needs, choose **Review**.

6. Choose **Exchange**, and then **Close**.

Old console

To exchange Convertible Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Reserved Instances**, select the Convertible Reserved Instances to exchange, and choose **Actions, Exchange Reserved Instance**.
3. Select the attributes of the desired configuration, and choose **Find Offering**.
4. Select a new Convertible Reserved Instance. The **Instance Count** column displays the number of Reserved Instances that you receive for the exchange. When you have selected a Convertible Reserved Instance that meets your needs, choose **Exchange**.

The Reserved Instances that were exchanged are retired, and the new Reserved Instances are displayed in the Amazon EC2 console. This process can take a few minutes to propagate.

Exchange a Convertible Reserved Instance using the command line interface

To exchange a Convertible Reserved Instance, first find a new Convertible Reserved Instance that meets your needs:

- [describe-reserved-instances-offerings](#) (AWS CLI)
- [Get-EC2ReservedInstancesOffering](#) (Tools for Windows PowerShell)

Get a quote for the exchange, which includes the number of Reserved Instances you get from the exchange, and the true-up cost for the exchange:

- [get-reserved-instances-exchange-quote](#) (AWS CLI)
- [GetEC2-ReservedInstancesExchangeQuote](#) (Tools for Windows PowerShell)

Finally, perform the exchange:

- [accept-reserved-instances-exchange-quote](#) (AWS CLI)
- [Confirm-EC2ReservedInstancesExchangeQuote](#) (Tools for Windows PowerShell)

Reserved Instance quotas

You can purchase new Reserved Instances each month. The number of new Reserved Instances that you can purchase each month is determined by your monthly quota, as follows:

Quota description	Default quota
New regional (p. 357) Reserved Instances	20 per Region per month
New zonal (p. 357) Reserved Instances	20 per Availability Zone per month

For example, in a Region with three Availability Zones, the default quota is 80 new Reserved Instances per month, calculated as follows:

- 20 regional Reserved Instances for the Region

- Plus 60 zonal Reserved Instances (20 for each of the three Availability Zones)

Quotas apply to running instances only. If your instance is pending, stopping, stopped, or hibernated, it does not count towards your quota.

View the number of Reserved Instances you have purchased

The number of Reserved Instances that you purchase is indicated by the **Instance count** field (console) or the `InstanceCount` parameter (AWS CLI). When you purchase new Reserved Instances, the quota is measured against the total instance count. For example, if you purchase a single Reserved Instance configuration with an instance count of 10, the purchase counts towards your quota as 10, not 1.

You can view how many Reserved Instances you have purchased by using the Amazon EC2 or the AWS CLI.

Console

To view the number of Reserved Instances you have purchased

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Reserved Instances**.
3. Select a Reserved Instance configuration from the table, and check the **Instance count** field.

In the following screenshot, the selected line represents a single Reserved Instance configuration for a `t3.micro` instance type. The **Instance count** column in the table view and the **Instance count** field in the detail view (outlined in the screenshot) indicate that there are 10 Reserved Instances for this configuration.

The screenshot shows the 'Reserved Instances' section of the EC2 console. A table lists configurations, with one row for `t3.micro` selected. The 'Instance count' column for this row is highlighted with a red box and contains the value '10'. Below the table, a detailed view for a specific Reserved Instance (ID: `2fbf16dd-98b6-4a3a-955f-83f87790f04b`) is displayed. The 'Instance count' field in this detail view is also highlighted with a red box and shows the value '10'.

AWS CLI

To view the number of Reserved Instances you have purchased

Use the [describe-reserved-instances](#) CLI command and specify the ID of the Reserved Instance configuration.

```
aws ec2 describe-reserved-instances \
--reserved-instance-ids 2fbf16dd-98b6-4a3a-955f-83f87790f04b \
--output table
```

Example output – The `InstanceCount` field indicates that there are 10 Reserved Instances for this configuration.

Considerations

A regional Reserved Instance applies a discount to a running On-Demand Instance. The default On-Demand Instance limit is 20. You cannot exceed your running On-Demand Instance limit by purchasing regional Reserved Instances. For example, if you already have 20 running On-Demand Instances, and you purchase 20 regional Reserved Instances, the 20 regional Reserved Instances are used to apply a discount to the 20 running On-Demand Instances. If you purchase more regional Reserved Instances, you will not be able to launch more instances because you have reached your On-Demand Instance limit.

Before purchasing regional Reserved Instances, make sure your On-Demand Instance limit matches or exceeds the number of regional Reserved Instances you intend to own. If required, make sure you request an increase to your On-Demand Instance limit *before* purchasing more regional Reserved Instances.

A zonal Reserved Instance—a Reserved Instance that is purchased for a specific Availability Zone—provides a capacity reservation as well as a discount. You *can exceed* your running On-Demand Instance limit by purchasing zonal Reserved Instances. For example, if you already have 20 running On-Demand Instances, and you purchase 20 zonal Reserved Instances, you can launch a further 20 On-Demand Instances that match the specifications of your zonal Reserved Instances, giving you a total of 40 running instances.

View your Reserved Instance quotas and request a quota increase

The Amazon EC2 console provides quota information. You can also request an increase in your quotas. For more information, see [View your current quotas \(p. 2100\)](#) and [Request an increase \(p. 2101\)](#).

Spot Instances

A Spot Instance is an instance that uses spare EC2 capacity that is available for less than the On-Demand price. Because Spot Instances enable you to request unused EC2 instances at steep discounts, you can lower your Amazon EC2 costs significantly. The hourly price for a Spot Instance is called a Spot price. The Spot price of each instance type in each Availability Zone is set by Amazon EC2, and is adjusted gradually based on the long-term supply of and demand for Spot Instances. Your Spot Instance runs whenever capacity is available.

Spot Instances are a cost-effective choice if you can be flexible about when your applications run and if your applications can be interrupted. For example, Spot Instances are well-suited for data analysis, batch jobs, background processing, and optional tasks. For more information, see [Amazon EC2 Spot Instances](#).

For a comparison of the different purchasing options for EC2 instances, see [Instance purchasing options \(p. 349\)](#).

Topics

- [Concepts \(p. 394\)](#)
- [How to get started \(p. 395\)](#)
- [Related services \(p. 395\)](#)
- [Pricing and savings \(p. 396\)](#)

Concepts

Before you get started with Spot Instances, you should be familiar with the following concepts:

- **Spot capacity pool** – A set of unused EC2 instances with the same instance type (for example, m5.large) and Availability Zone.
- **Spot price** – The current price of a Spot Instance per hour.
- **Spot Instance request** – Requests a Spot Instance. When capacity is available, Amazon EC2 fulfills your request. A Spot Instance request is either *one-time* or *persistent*. Amazon EC2 automatically resubmits a persistent Spot Instance request after the Spot Instance associated with the request is interrupted.
- **EC2 instance rebalance recommendation** – Amazon EC2 emits an instance rebalance recommendation signal to notify you that a Spot Instance is at an elevated risk of interruption. This signal provides an opportunity to proactively rebalance your workloads across existing or new Spot Instances without having to wait for the two-minute Spot Instance interruption notice.
- **Spot Instance interruption** – Amazon EC2 terminates, stops, or hibernates your Spot Instance when Amazon EC2 needs the capacity back. Amazon EC2 provides a Spot Instance interruption notice, which gives the instance a two-minute warning before it is interrupted.

Key differences between Spot Instances and On-Demand Instances

The following table lists the key differences between Spot Instances and [On-Demand Instances \(p. 351\)](#).

	Spot Instances	On-Demand Instances
Launch time	Can only be launched immediately if the Spot Instance request is active and capacity is available.	Can only be launched immediately if you make a manual launch request and capacity is available.
Available capacity	If capacity is not available, the Spot Instance request continues to	If capacity is not available when you make a launch request, you get an insufficient capacity error (ICE).

	Spot Instances	On-Demand Instances
	automatically make the launch request until capacity becomes available.	
Hourly price	The hourly price for Spot Instances varies based on long-term supply and demand.	The hourly price for On-Demand Instances is static.
Rebalance recommendation	The signal that Amazon EC2 emits for a running Spot Instance when the instance is at an elevated risk of interruption.	You determine when an On-Demand Instance is interrupted (stopped, hibernated, or terminated).
Instance interruption	You can stop and start an Amazon EBS-backed Spot Instance. In addition, Amazon EC2 can interrupt (p. 433) an individual Spot Instance if capacity is no longer available.	You determine when an On-Demand Instance is interrupted (stopped, hibernated, or terminated).

How to get started

The first thing that you need to do is get set up to use Amazon EC2. It can also be helpful to have experience launching On-Demand Instances before launching Spot Instances.

Get up and running

- [Set up to use Amazon EC2 \(p. 7\)](#)
- [Tutorial: Get started with Amazon EC2 Windows instances \(p. 14\)](#)

Spot basics

- [How Spot Instances work \(p. 400\)](#)

Working with Spot Instances

- [Create a Spot Instance request \(p. 407\)](#)
- [Get request status information \(p. 426\)](#)
- [Spot Instance interruptions \(p. 433\)](#)

Related services

You can provision Spot Instances directly using Amazon EC2. You can also provision Spot Instances using other services in AWS. For more information, see the following documentation.

Amazon EC2 Auto Scaling and Spot Instances

You can create launch templates or configurations so that Amazon EC2 Auto Scaling can launch Spot Instances. For more information, see [Requesting Spot Instances for fault-tolerant and flexible applications](#) and [Auto Scaling groups with multiple instance types and purchase options](#) in the [Amazon EC2 Auto Scaling User Guide](#).

Amazon EMR and Spot Instances

There are scenarios where it can be useful to run Spot Instances in an Amazon EMR cluster. For more information, see [Spot Instances](#) and [When Should You Use Spot Instances](#) in the [Amazon EMR Management Guide](#).

AWS CloudFormation templates

AWS CloudFormation enables you to create and manage a collection of AWS resources using a template in JSON format. For more information, see [EC2 Spot Instance Updates - Auto Scaling and CloudFormation Integration](#).

AWS SDK for Java

You can use the Java programming language to manage your Spot Instances. For more information, see [Tutorial: Amazon EC2 Spot Instances](#) and [Tutorial: Advanced Amazon EC2 Spot Request Management](#).

AWS SDK for .NET

You can use the .NET programming environment to manage your Spot Instances. For more information, see [Tutorial: Amazon EC2 Spot Instances](#).

Pricing and savings

You pay the Spot price for Spot Instances, which is set by Amazon EC2 and adjusted gradually based on the long-term supply of and demand for Spot Instances. Your Spot Instances run until you terminate them, capacity is no longer available, or your Amazon EC2 Auto Scaling group terminates them during [scale in](#).

If you or Amazon EC2 interrupts a running Spot Instance, you are charged for the seconds used or the full hour, or you receive no charge, depending on the operating system used and who interrupted the Spot Instance. For more information, see [Billing for interrupted Spot Instances \(p. 443\)](#).

[View prices](#)

To view the current (updated every five minutes) lowest Spot price per AWS Region and instance type, see the [Amazon EC2 Spot Instances Pricing](#) page.

To view the Spot price history for the past three months, use the Amazon EC2 console or the [describe-spot-price-history](#) command (AWS CLI). For more information, see [Spot Instance pricing history \(p. 401\)](#).

We independently map Availability Zones to codes for each AWS account. Therefore, you can get different results for the same Availability Zone code (for example, us-west-2a) between different accounts.

[View savings](#)

You can view the savings made from using Spot Instances for a single [Spot Fleet \(p. 1025\)](#) or for all Spot Instances. You can view the savings made in the last hour or the last three days, and you can view the average cost per vCPU hour and per memory (GiB) hour. Savings are estimated and may differ from actual savings because they do not include the billing adjustments for your usage. For more information about viewing savings information, see [Savings from purchasing Spot Instances \(p. 402\)](#).

[View billing](#)

Your bill provides details about your service usage. For more information, see [Viewing your bill](#) in the [AWS Billing User Guide](#).

Best practices for EC2 Spot

Amazon EC2 Spot Instances are spare EC2 compute capacity in the AWS Cloud that are available to you at savings of up to 90% off compared to On-Demand prices. The only difference between On-Demand Instances and Spot Instances is that Spot Instances can be interrupted by Amazon EC2, with two minutes of notification, when Amazon EC2 needs the capacity back.

Spot Instances are recommended for stateless, fault-tolerant, flexible applications. For example, Spot Instances work well for big data, containerized workloads, CI/CD, stateless web servers, high performance computing (HPC), and rendering workloads.

While running, Spot Instances are exactly the same as On-Demand Instances. However, Spot does not guarantee that you can keep your running instances long enough to finish your workloads. Spot also does not guarantee that you can get immediate availability of the instances that you are looking for, or that you can always get the aggregate capacity that you requested. Moreover, Spot Instance interruptions and capacity can change over time because Spot Instance availability varies based on supply and demand, and past performance isn't a guarantee of future results.

Spot Instances are not suitable for workloads that are inflexible, stateful, fault-intolerant, or tightly coupled between instance nodes. They're also not recommended for workloads that are intolerant of occasional periods when the target capacity is not completely available. We strongly warn against using Spot Instances for these workloads or attempting to fail-over to On-Demand Instances to handle interruptions.

Regardless of whether you're an experienced Spot user or new to Spot Instances, if you are currently experiencing issues with Spot Instance interruptions or availability, we recommend that you follow these best practices to have the best experience using the Spot service.

Spot best practices

- [Prepare individual instances for interruptions \(p. 397\)](#)
- [Be flexible about instance types and Availability Zones \(p. 398\)](#)
- [Use EC2 Auto Scaling groups or Spot Fleet to manage your aggregate capacity \(p. 398\)](#)
- [Use the price and capacity optimized allocation strategy \(p. 398\)](#)
- [Use proactive capacity rebalancing \(p. 398\)](#)
- [Use integrated AWS services to manage your Spot Instances \(p. 398\)](#)
- [Which is the best Spot request method to use? \(p. 399\)](#)

Prepare individual instances for interruptions

The best way for you to gracefully handle Spot Instance interruptions is to architect your application to be fault-tolerant. To accomplish this, you can take advantage of EC2 instance rebalance recommendations and Spot Instance interruption notices.

An EC2 Instance rebalance recommendation is a new signal that notifies you when a Spot Instance is at elevated risk of interruption. The signal gives you the opportunity to proactively manage the Spot Instance in advance of the two-minute Spot Instance interruption notice. You can decide to rebalance your workload to new or existing Spot Instances that are not at an elevated risk of interruption. We've made it easy for you to use this new signal by using the Capacity Rebalancing feature in Auto Scaling groups and Spot Fleet. For more information, see [Use proactive capacity rebalancing \(p. 398\)](#).

A Spot Instance interruption notice is a warning that is issued two minutes before Amazon EC2 interrupts a Spot Instance. If your workload is "time-flexible," you can configure your Spot Instances to be stopped or hibernated, instead of being terminated, when they are interrupted. Amazon EC2 automatically stops or hibernates your Spot Instances on interruption, and automatically resumes the instances when we have available capacity.

We recommend that you create a rule in [Amazon EventBridge](#) that captures the rebalance recommendations and interruption notifications, and then triggers a checkpoint for the progress of your workload or gracefully handles the interruption. For more information, see [Monitor rebalance recommendation signals \(p. 430\)](#). For a detailed example that walks you through how to create and use event rules, see [Taking Advantage of Amazon EC2 Spot Instance Interruption Notices](#).

For more information, see [EC2 instance rebalance recommendations \(p. 429\)](#) and [Spot Instance interruptions \(p. 433\)](#).

Be flexible about instance types and Availability Zones

A Spot capacity pool is a set of unused EC2 instances with the same instance type (for example, m5.1.large) and Availability Zone (for example, us-east-1a). You should be flexible about which instance types you request and in which Availability Zones you can deploy your workload. This gives Spot a better chance to find and allocate your required amount of compute capacity. For example, don't just ask for c5.1.large if you'd be willing to use larges from the c4, m5, and m4 families.

Depending on your specific needs, you can evaluate which instance types you can be flexible across to fulfill your compute requirements. If a workload can be vertically scaled, you should include larger instance types (more vCPUs and memory) in your requests. If you can only scale horizontally, you should include older generation instance types because they are less in demand from On-Demand customers.

A good rule of thumb is to be flexible across at least 10 instance types for each workload. In addition, make sure that all Availability Zones are configured for use in your VPC and selected for your workload.

Use EC2 Auto Scaling groups or Spot Fleet to manage your aggregate capacity

Spot enables you to think in terms of aggregate capacity—in units that include vCPUs, memory, storage, or network throughput—rather than thinking in terms of individual instances. Auto Scaling groups and Spot Fleet enable you to launch and maintain a target capacity, and to automatically request resources to replace any that are disrupted or manually terminated. When you configure an Auto Scaling group or a Spot Fleet, you need only specify the instance types and target capacity based on your application needs. For more information, see [Auto Scaling groups](#) in the *Amazon EC2 Auto Scaling User Guide* and [Create a Spot Fleet request \(p. 1058\)](#) in this user guide.

Use the price and capacity optimized allocation strategy

Allocation strategies in Auto Scaling groups help you to provision your target capacity without the need to manually look for the Spot capacity pools with spare capacity. We recommend using the price-capacity-optimized strategy because this strategy automatically provisions instances from the most-available Spot capacity pools that also have the lowest possible price. You can also take advantage of the price-capacity-optimized allocation strategy in Spot Fleet. Because your Spot Instance capacity is sourced from pools with optimal capacity, this decreases the possibility that your Spot Instances are reclaimed. For more information about allocation strategies, see [Spot Instances](#) in the *Amazon EC2 Auto Scaling User Guide* and [When workloads have a high cost of interruption \(p. 1028\)](#) in this user guide.

Use proactive capacity rebalancing

Capacity Rebalancing helps you maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running Spot Instance receives the two-minute Spot Instance interruption notice. When Capacity Rebalancing is enabled, Auto Scaling or Spot Fleet attempts to proactively replace Spot Instances that have received a rebalance recommendation, providing the opportunity to rebalance your workload to new Spot Instances that are not at elevated risk of interruption.

Capacity Rebalancing complements the price-capacity-optimized allocation strategy (which is designed to help find the most optimal spare capacity) and the mixed instances policy (which is designed to enhance availability by deploying instances across multiple instance types running in multiple Availability Zones).

For more information, see [Capacity Rebalancing \(p. 1044\)](#).

Use integrated AWS services to manage your Spot Instances

Other AWS services integrate with Spot to reduce overall compute costs without the need to manage the individual instances or fleets. We recommend that you consider the following solutions for your applicable workloads: Amazon EMR, Amazon Elastic Container Service, AWS Batch, Amazon Elastic Kubernetes Service, Amazon SageMaker, AWS Elastic Beanstalk, and Amazon GameLift. To learn more about Spot best practices with these services, see the [Amazon EC2 Spot Instances Workshops Website](#).

Which is the best Spot request method to use?

Use the following table to determine which API to use when requesting Spot Instances.

API	When to use?	Use case	Should I use this API?
CreateAutoScalingGroup	<ul style="list-style-type: none"> • You need multiple instances with either a single configuration or a mixed configuration. • You want to automate the lifecycle management through a configurable API. 	Create an Auto Scaling group that manages the lifecycle of your instances while maintaining the desired number of instances. Supports horizontal scaling (adding more instances) between specified minimum and maximum limits.	Yes
CreateFleet	<ul style="list-style-type: none"> • You need multiple instances with either a single configuration or a mixed configuration. • You want to self-manage your instance lifecycle. • If you don't need auto scaling, we recommend that you use an instant type fleet. 	Create a fleet of both On-Demand Instances and Spot Instances in a single request, with multiple launch specifications that vary by instance type, AMI, Availability Zone, or subnet. The Spot Instance allocation strategy defaults to lowest-price per unit, but you can change it to price-capacity-optimized, capacity-optimized, or diversified.	Yes – in instant mode if you don't need auto scaling
RunInstances	<ul style="list-style-type: none"> • You're already using the RunInstances API to launch On-Demand Instances, and you simply want to change to launching Spot Instances by changing a single parameter. • You do not need multiple instances with different instance types. 	Launch a specified number of instances using an AMI and one instance type.	No – because RunInstances does not allow mixed instance types in a single request
RequestSpotFleet	<ul style="list-style-type: none"> • We strongly discourage using the RequestSpotFleet API because it is a legacy API with no planned investment. 	DO NOT USE. RequestSpotFleet is legacy API with no planned investment.	No

API	When to use?	Use case	Should I use this API?

How Spot Instances work

To launch a Spot Instance, either you create a *Spot Instance request*, or Amazon EC2 creates a Spot Instance request on your behalf. The Spot Instance launches when the Spot Instance request is fulfilled.

You can launch a Spot Instance using several different services. For more information, see [Getting Started with Amazon EC2 Spot Instances](#). In this user guide, we describe the following ways to launch a Spot Instance using EC2:

- You can create a Spot Instance request by using the [launch instance wizard \(p. 552\)](#) in the Amazon EC2 console or the [run-instances](#) AWS CLI command. For more information, see [Create a Spot Instance request \(p. 407\)](#).
- You can create an EC2 Fleet, in which you specify the desired number of Spot Instances. Amazon EC2 creates a Spot Instance request on your behalf for every Spot Instance that is specified in the EC2 Fleet. For more information, see [Create an EC2 Fleet \(p. 1013\)](#).
- You can create a Spot Fleet request, in which you specify the desired number of Spot Instances. Amazon EC2 creates a Spot Instance request on your behalf for every Spot Instance that is specified in the Spot Fleet request. For more information, see [Create a Spot Fleet request \(p. 1058\)](#).

Your Spot Instance launches if there is available capacity.

Your Spot Instance runs until you stop or terminate it, or until Amazon EC2 interrupts it (known as a *Spot Instance interruption*).

When you use Spot Instances, you must be prepared for interruptions. Amazon EC2 can interrupt your Spot Instance when the demand for Spot Instances rises or when the supply of Spot Instances decreases. When Amazon EC2 interrupts a Spot Instance, it provides a Spot Instance interruption notice, which gives the instance a two-minute warning before Amazon EC2 interrupts it. You can't enable termination protection for Spot Instances. For more information, see [Spot Instance interruptions \(p. 433\)](#).

You can stop, start, reboot, or terminate an Amazon EBS-backed Spot Instance. The Spot service can stop, terminate, or hibernate a Spot Instance when it interrupts it.

Contents

- [Launch Spot Instances in a launch group \(p. 401\)](#)
- [Launch Spot Instances in an Availability Zone group \(p. 401\)](#)

- [Launch Spot Instances in a VPC \(p. 401\)](#)

Launch Spot Instances in a launch group

Specify a launch group in your Spot Instance request to tell Amazon EC2 to launch a set of Spot Instances only if it can launch them all. In addition, if the Spot service must terminate one of the instances in a launch group, it must terminate them all. However, if you terminate one or more of the instances in a launch group, Amazon EC2 does not terminate the remaining instances in the launch group.

Although this option can be useful, adding this constraint can decrease the chances that your Spot Instance request is fulfilled and increase the chances that your Spot Instances are terminated. For example, your launch group includes instances in multiple Availability Zones. If capacity in one of these Availability Zones decreases and is no longer available, then Amazon EC2 terminates all instances for the launch group.

If you create another successful Spot Instance request that specifies the same (existing) launch group as an earlier successful request, then the new instances are added to the launch group. Subsequently, if an instance in this launch group is terminated, all instances in the launch group are terminated, which includes instances launched by the first and second requests.

Launch Spot Instances in an Availability Zone group

Specify an Availability Zone group in your Spot Instance request to tell Amazon EC2 to launch a set of Spot Instances in the same Availability Zone. Amazon EC2 need not interrupt all instances in an Availability Zone group at the same time. If Amazon EC2 must interrupt one of the instances in an Availability Zone group, the others remain running.

Although this option can be useful, adding this constraint can lower the chances that your Spot Instance request is fulfilled.

If you specify an Availability Zone group but don't specify an Availability Zone in the Spot Instance request, the result depends on the network you specified.

Default VPC

Amazon EC2 uses the Availability Zone for the specified subnet. If you don't specify a subnet, it selects an Availability Zone and its default subnet, but not necessarily the lowest-priced zone. If you deleted the default subnet for an Availability Zone, then you must specify a different subnet.

Nondefault VPC

Amazon EC2 uses the Availability Zone for the specified subnet.

Launch Spot Instances in a VPC

You specify a subnet for your Spot Instances the same way that you specify a subnet for your On-Demand Instances.

- [Default VPC] If you want your Spot Instance launched in a specific low-priced Availability Zone, you must specify the corresponding subnet in your Spot Instance request. If you do not specify a subnet, Amazon EC2 selects one for you, and the Availability Zone for this subnet might not have the lowest Spot price.
- [Nondefault VPC] You must specify the subnet for your Spot Instance.

Spot Instance pricing history

Spot Instance prices are set by Amazon EC2 and adjust gradually based on long-term trends in supply and demand for Spot Instance capacity.

When your Spot request is fulfilled, your Spot Instances launch at the current Spot price, not exceeding the On-Demand price. You can view the Spot price history for the last 90 days, filtering by instance type, operating system, and Availability Zone.

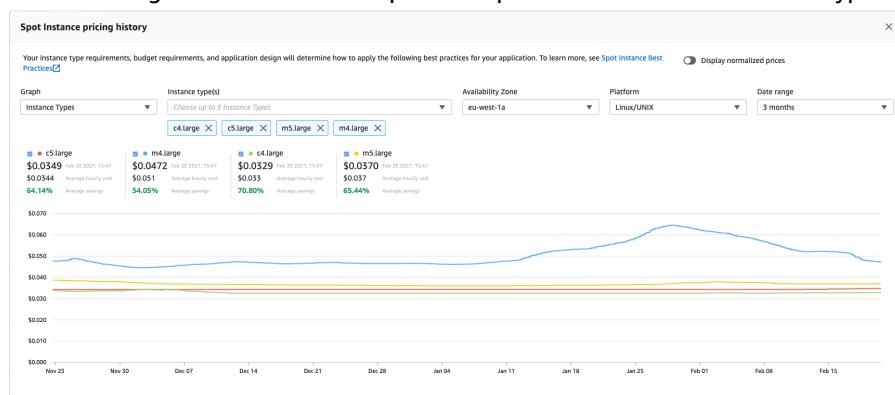

To view the current Spot prices

For the *current* Spot Instance prices, see [Amazon EC2 Spot Instances Pricing](#).

To view the Spot price history (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests**.
3. Choose **Pricing history**.
4. For **Graph**, choose to compare the price history by **Availability Zones** or by **Instance Types**.
 - If you choose **Availability Zones**, then choose the **Instance type**, operating system (**Platform**), and **Date range** for which to view the price history.
 - If you choose **Instance Types**, then choose up to five **Instance type(s)**, the **Availability Zone**, operating system (**Platform**), and **Date range** for which to view the price history.

The following screenshot shows a price comparison for different instance types.

5. Hover (move your pointer) over the graph to display the prices at specific times in the selected date range. The prices are displayed in the information blocks above the graph. The price displayed in the top row shows the price on a specific date. The price displayed in the second row shows the average price over the selected date range.
6. To display the price per vCPU, toggle on **Display normalized prices**. To display the price for the instance type, toggle off **Display normalized prices**.

To view the Spot price history using the command line

You can use one of the following commands. For more information, see [Access Amazon EC2 \(p. 5\)](#).

- [describe-spot-price-history](#) (AWS CLI)
- [Get-EC2SpotPriceHistory](#) (AWS Tools for Windows PowerShell)

Savings from purchasing Spot Instances

You can view the usage and savings information for Spot Instances at the per-fleet level, or for all running Spot Instances. At the per-fleet level, the usage and savings information includes all instances

launched and terminated by the fleet. You can view this information from the last hour or the last three days.

The following screenshot from the **Savings** section shows the Spot usage and savings information for a Spot Fleet.

Spot usage and savings																																		
4 Spot Instances	266 vCPU-hours	700 Mem(GiB)-hours	\$9.55 On-Demand total	\$2.99 Spot total	69% Savings																													
				\$0.0112 Average cost per vCPU-hour	\$0.0043 Average cost per mem(GiB)-hour																													
Details																																		
<table border="1"><thead><tr><th></th><th></th><th></th><th></th><th></th><th></th><th></th></tr></thead><tbody><tr><td>t3.medium (1)</td><td>2 vCPU hours</td><td>4 mem(GiB)-hours</td><td>\$0.01 total</td><td>70% savings</td><td></td><td></td></tr><tr><td>m4.large (1)</td><td>144 vCPU hours</td><td>576 mem(GiB)-hours</td><td>\$2.52 total</td><td>68% savings</td><td></td><td></td></tr><tr><td>t2.micro (2)</td><td>120 vCPU hours</td><td>120 mem(GiB)-hours</td><td>\$0.46 total</td><td>70% savings</td><td></td><td></td></tr></tbody></table>														t3.medium (1)	2 vCPU hours	4 mem(GiB)-hours	\$0.01 total	70% savings			m4.large (1)	144 vCPU hours	576 mem(GiB)-hours	\$2.52 total	68% savings			t2.micro (2)	120 vCPU hours	120 mem(GiB)-hours	\$0.46 total	70% savings		
t3.medium (1)	2 vCPU hours	4 mem(GiB)-hours	\$0.01 total	70% savings																														
m4.large (1)	144 vCPU hours	576 mem(GiB)-hours	\$2.52 total	68% savings																														
t2.micro (2)	120 vCPU hours	120 mem(GiB)-hours	\$0.46 total	70% savings																														

You can view the following usage and savings information:

- **Spot Instances** – The number of Spot Instances launched and terminated by the Spot Fleet. When viewing the savings summary, the number represents all your running Spot Instances.
- **vCPU-hours** – The number of vCPU hours used across all the Spot Instances for the selected time frame.
- **Mem(GiB)-hours** – The number of GiB hours used across all the Spot Instances for the selected time frame.
- **On-Demand total** – The total amount you would've paid for the selected time frame had you launched these instances as On-Demand Instances.
- **Spot total** – The total amount to pay for the selected time frame.
- **Savings** – The percentage that you are saving by not paying the On-Demand price.
- **Average cost per vCPU-hour** – The average hourly cost of using the vCPUs across all the Spot Instances for the selected time frame, calculated as follows: **Average cost per vCPU-hour = Spot total / vCPU-hours**.
- **Average cost per mem(GiB)-hour** – The average hourly cost of using the GiBs across all the Spot Instances for the selected time frame, calculated as follows: **Average cost per mem(GiB)-hour = Spot total / Mem(GiB)-hours**.
- **Details** table – The different instance types (the number of instances per instance type is in parentheses) that comprise the Spot Fleet. When viewing the savings summary, these comprise all your running Spot Instances.

Savings information can only be viewed using the Amazon EC2 console.

To view the savings information for a Spot Fleet (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation pane, choose **Spot Requests**.
3. Select the ID of a Spot Fleet request and scroll to the **Savings** section.

Alternatively, select the check box next to the Spot Fleet request ID and choose the **Savings** tab.

4. By default, the page displays usage and savings information for the last three days. You can choose **last hour** or the **last three days**. For Spot Fleets that were launched less than an hour ago, the page shows the estimated savings for the hour.

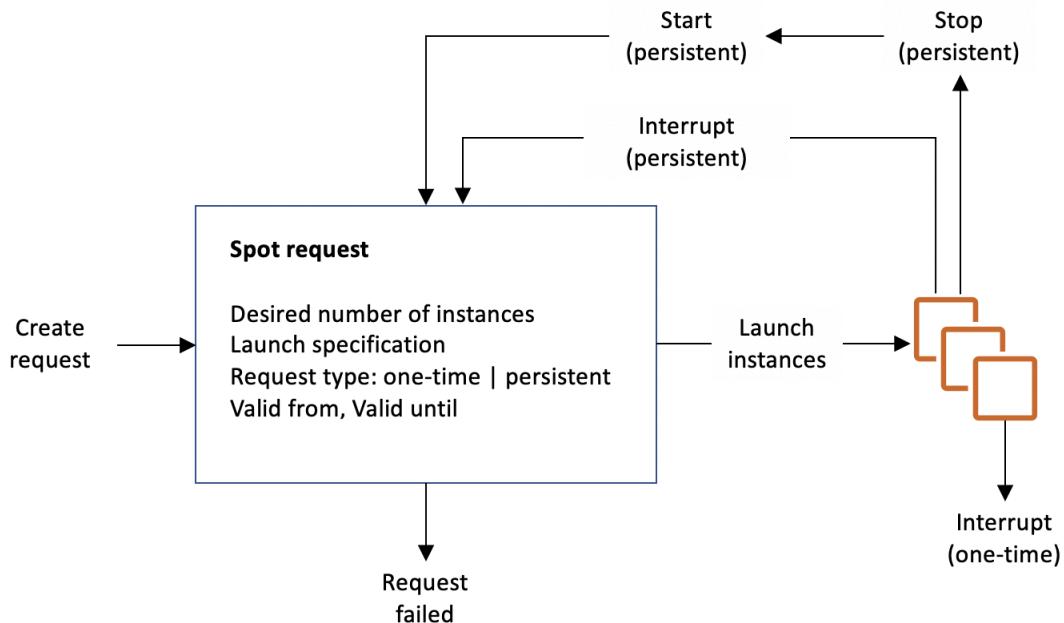

To view the savings information for all running Spot Instances (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the navigation pane, choose **Spot Requests**.
3. Choose **Savings summary**.

Work with Spot Instances

To use Spot Instances, you create a Spot Instance request that includes the desired number of instances, the instance type, and the Availability Zone. If capacity is available, Amazon EC2 fulfills your request immediately. Otherwise, Amazon EC2 waits until your request can be fulfilled or until you cancel the request.

The following illustration shows how Spot Instance requests work. Notice that the request type (one-time or persistent) determines whether the request is opened again when Amazon EC2 interrupts a Spot Instance or if you stop a Spot Instance. If the request is persistent, the request is opened again after your Spot Instance is interrupted. If the request is persistent and you stop your Spot Instance, the request only opens after you start your Spot Instance.

Contents

- [Start a Spot Instance \(p. 419\)](#)

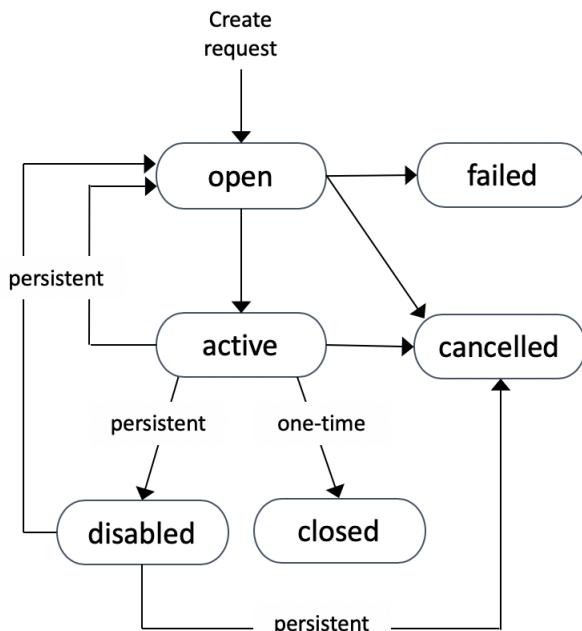

- [Terminate a Spot Instance \(p. 420\)](#)
- [Spot Instance request example launch specifications \(p. 421\)](#)

Spot Instance request states

A Spot Instance request can be in one of the following states:

- open – The request is waiting to be fulfilled.
- active – The request is fulfilled and has an associated Spot Instance.
- failed – The request has one or more bad parameters.
- closed – The Spot Instance was interrupted or terminated.
- disabled – You stopped the Spot Instance.
- cancelled – You canceled the request, or the request expired.

The following illustration represents the transitions between the request states. Notice that the transitions depend on the request type (one-time or persistent).

A one-time Spot Instance request remains active until Amazon EC2 launches the Spot Instance, the request expires, or you cancel the request. If capacity is not available, your Spot Instance is terminated and the Spot Instance request is closed.

A persistent Spot Instance request remains active until it expires or you cancel it, even if the request is fulfilled. If capacity is not available, your Spot Instance is interrupted. After your instance is interrupted, when capacity becomes available again, the Spot Instance is started if stopped or resumed if hibernated. You can stop a Spot Instance and start it again if capacity is available. If the Spot Instance is terminated (irrespective of whether the Spot Instance is in a stopped or running state), the Spot Instance request is opened again and Amazon EC2 launches a new Spot Instance. For more information, see [Stop a Spot Instance \(p. 419\)](#), [Start a Spot Instance \(p. 419\)](#), and [Terminate a Spot Instance \(p. 420\)](#).

You can track the status of your Spot Instance requests, as well as the status of the Spot Instances launched, through the status. For more information, see [Spot request status \(p. 423\)](#).

Specify a tenancy for your Spot Instances

You can run a Spot Instance on single-tenant hardware. Dedicated Spot Instances are physically isolated from instances that belong to other AWS accounts. For more information, see [Dedicated Instances \(p. 499\)](#) and the [Amazon EC2 Dedicated Instances](#) product page.

To run a Dedicated Spot Instance, do one of the following:

- Specify a tenancy of dedicated when you create the Spot Instance request. For more information, see [Create a Spot Instance request \(p. 407\)](#).
- Request a Spot Instance in a VPC with an instance tenancy of dedicated. For more information, see [Create a VPC with a dedicated instance tenancy \(p. 502\)](#). You cannot request a Spot Instance with a tenancy of default if you request it in a VPC with an instance tenancy of dedicated.

All instance families support Dedicated Spot Instances except T instances. For each supported instance family, only the largest instance size or metal size supports Dedicated Spot Instances.

Service-linked role for Spot Instance requests

Amazon EC2 uses service-linked roles for the permissions that it requires to call other AWS services on your behalf. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles provide a secure way to delegate permissions to AWS services because only the linked service can assume a service-linked role. For more information, see [Using Service-Linked Roles](#) in the *IAM User Guide*.

Amazon EC2 uses the service-linked role named **AWSServiceRoleForEC2Spot** to launch and manage Spot Instances on your behalf.

Permissions granted by **AWSServiceRoleForEC2Spot**

Amazon EC2 uses **AWSServiceRoleForEC2Spot** to complete the following actions:

- `ec2:DescribeInstances` – Describe Spot Instances
- `ec2:StopInstances` – Stop Spot Instances
- `ec2:StartInstances` – Start Spot Instances

Create the service-linked role

Under most circumstances, you don't need to manually create a service-linked role. Amazon EC2 creates the **AWSServiceRoleForEC2Spot** service-linked role the first time you request a Spot Instance using the console.

If you had an active Spot Instance request before October 2017, when Amazon EC2 began supporting this service-linked role, Amazon EC2 created the **AWSServiceRoleForEC2Spot** role in your AWS account. For more information, see [A New Role Appeared in My Account](#) in the *IAM User Guide*.

If you use the AWS CLI or an API to request a Spot Instance, you must first ensure that this role exists.

To create **AWSServiceRoleForEC2Spot** using the console

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. On the **Select type of trusted entity** page, choose **EC2, EC2 - Spot Instances, Next: Permissions**.
5. On the next page, choose **Next:Review**.
6. On the **Review** page, choose **Create role**.

To create AWSServiceRoleForEC2Spot using the AWS CLI

Use the [create-service-linked-role](#) command as follows.

```
aws iam create-service-linked-role --aws-service-name spot.amazonaws.com
```

If you no longer need to use Spot Instances, we recommend that you delete the **AWSServiceRoleForEC2Spot** role. After this role is deleted from your account, Amazon EC2 will create the role again if you request Spot Instances.

Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots

If you specify an [encrypted AMI \(p. 193\)](#) or an [encrypted Amazon EBS snapshot \(p. 1921\)](#) for your Spot Instances and you use a customer managed key for encryption, you must grant the **AWSServiceRoleForEC2Spot** role permission to use the customer managed key so that Amazon EC2 can launch Spot Instances on your behalf. To do this, you must add a grant to the customer managed key, as shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see [Using Grants](#) and [Using Key Policies in AWS KMS](#) in the *AWS Key Management Service Developer Guide*.

To grant the AWSServiceRoleForEC2Spot role permissions to use the customer managed key

- Use the [create-grant](#) command to add a grant to the customer managed key and to specify the principal (the **AWSServiceRoleForEC2Spot** service-linked role) that is given permission to perform the operations that the grant permits. The customer managed key is specified by the key-id parameter and the ARN of the customer managed key. The principal is specified by the grantee-principal parameter and the ARN of the **AWSServiceRoleForEC2Spot** service-linked role.

```
aws kms create-grant \
  --region us-east-1 \
  --key-id arn:aws:kms:us-
east-1:44445556666:key/1234abcd-12ab-34cd-56ef-1234567890ab \
  --grantee-principal arn:aws:iam::111122223333:role/aws-service-role/
spot.amazonaws.com/AWSServiceRoleForEC2Spot \
  --operations "Decrypt" "Encrypt" "GenerateDataKey"
"GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom"
"ReEncryptTo"
```

Create a Spot Instance request

You can use the [launch instance wizard \(p. 552\)](#) in the Amazon EC2 console or the [run-instances](#) AWS CLI command to request a Spot Instance in the same way that you can launch an On-Demand Instance. This method is only recommended for the following reasons:

- You're already using the [launch instance wizard \(p. 552\)](#) or [run-instances](#) command to launch On-Demand Instances, and you simply want to change to launching Spot Instances by changing a single parameter.
- You do not need multiple instances with different instance types.

This method is generally not recommended for launching Spot Instances because you can't specify multiple instance types, and you can't launch Spot Instances and On-Demand Instances in the same request. For the preferred methods for launching Spot Instances, which include launching a *fleet* that includes Spot Instances and On-Demand Instances with multiple instance types, see [Which is the best Spot request method to use? \(p. 399\)](#)

If you request multiple Spot Instances at one time, Amazon EC2 creates separate Spot Instance requests so that you can track the status of each request separately. For more information about tracking Spot Instance requests, see [Spot request status \(p. 423\)](#).

New console

To create a Spot Instance request using the launch instance wizard

Steps 1–9 are the same steps you'd use to launch an On-Demand Instance. At Step 10, you configure the Spot Instance request.

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, select a Region.
3. From the Amazon EC2 console dashboard, choose **Launch instance**.
4. (Optional) Under **Name and tags**, you can name your instance, and tag the Spot Instance request, the instance, the volumes, and the elastic graphics. For information about tags, see [Tag your Amazon EC2 resources \(p. 2085\)](#).
 - a. For **Name**, enter a descriptive name for your instance.

The instance name is a tag, where the key is **Name**, and the value is the name that you specify. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.

- b. To tag the Spot Instance request, the instance, the volumes, and the elastic graphics, choose **Add additional tags**. Choose **Add tag**, and then enter a key and value, and select the resource type to tag. Choose **Add tag** again for each additional tag to add.
5. Under **Application and OS Images (Amazon Machine Image)**, choose the operating system (OS) for your instance, and then select an AMI. For more information, see [Application and OS Images \(Amazon Machine Image\) \(p. 555\)](#).
6. Under **Instance type**, select the instance type that meets your requirements for the hardware configuration and size of your instance. For more information, see [Instance type \(p. 556\)](#).
7. Under **Key pair (login)**, choose an existing key pair, or choose **Create new key pair** to create a new one. For more information, see [Amazon EC2 key pairs and Windows instances \(p. 1662\)](#).

Important

If you choose the **Proceed without key pair (Not recommended)** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

8. Under **Network settings**, use the default settings, or choose **Edit** to configure the network settings as necessary.

Security groups form part of the network settings, and define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance.

For more information, see [Network settings \(p. 556\)](#).

9. The AMI you selected includes one or more volumes of storage, including the root device volume. Under **Configure storage**, you can specify additional volumes to attach to the instance by choosing **Add new volume**. For more information, see [Configure storage \(p. 558\)](#).
10. Under **Advanced details**, configure the Spot Instance request as follows:
 - a. Under **Purchasing option**, select the **Request Spot Instances** check box.
 - b. You can either keep the default configuration for the Spot Instance request, or choose **Customize** (at the right) to specify custom settings for your Spot Instance request.

When you choose **Customize**, the following fields appear.

- i. **Maximum price:** You can request Spot Instances at the Spot price, capped at the On-Demand price, or you can specify the maximum amount you're willing to pay.

Warning

If you specify a maximum price, your instances will be interrupted more frequently than if you choose **No maximum price**.

- **No maximum price:** Your Spot Instance will launch at the current Spot price. The price will never exceed the On-Demand price. (Recommended)
- **Set your maximum price (per instance/hour):** You can specify the maximum amount you're willing to pay.
 - If you specify a maximum price that is less than the current Spot price, your Spot Instance will not launch.
 - If you specify a maximum price that is more than the current Spot price, your Spot Instance will launch and be charged at the current Spot price. After your Spot Instance is running, if the Spot price rises above your maximum price, Amazon EC2 interrupts your Spot Instance.
 - Regardless of the maximum price you specify, you will always be charged the current Spot price.

To review Spot price trends, see [Spot Instance pricing history \(p. 401\)](#).

- ii. **Request type:** The Spot Instance request type that you choose determines what happens if your Spot Instance is interrupted.

- **One-time:** Amazon EC2 places a one-time request for your Spot Instance. If your Spot Instance is interrupted, the request is not resubmitted.
- **Persistent request:** Amazon EC2 places a persistent request for your Spot Instance. If your Spot Instance is interrupted, the request is resubmitted to replenish the interrupted Spot Instance.

If you do not specify a value, the default is a one-time request.

- iii. **Valid to:** The expiration date of a *persistent* Spot Instance request.

This field is not supported for one-time requests. A *one-time* request remains active until all the instances in the request launch or you cancel the request.

- **No request expiry date:** The request remains active until you cancel it.
- **Set your request expiry date:** The persistent request remains active until the date that you specify, or until you cancel it.

- iv. **Interruption behavior:** The behavior that you choose determines what happens when a Spot Instance is interrupted.

- For persistent requests, valid values are **Stop** and **Hibernate**. When an instance is stopped, charges for EBS volume storage apply.
- For one-time requests, only **Terminate** is valid.

If you do not specify a value, the default is **Terminate**, which is not valid for a persistent Spot Instance request. If you keep the default and try to launch a persistent Spot Instance request, you'll get an error.

For more information, see [Interruption behavior \(p. 434\)](#).

11. On the **Summary** panel, for **Number of instances**, enter the number of instances to launch.

Note

Amazon EC2 creates a separate request for each Spot Instance.

12. On the **Summary** panel, review the details of your instance, and make any necessary changes. After you submit your Spot Instance request, you can't change the parameters of the request. You can navigate directly to a section in the launch instance wizard by choosing its link in the **Summary** panel. For more information, see [Summary \(p. 561\)](#).
13. When you're ready to launch your instance, choose **Launch instance**.

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 2114\)](#).

Old console

To create a Spot Instance request using the launch instance wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, select a Region.
3. From the Amazon EC2 console dashboard, choose **Launch Instance**.
4. On the **Choose an Amazon Machine Image (AMI)** page, choose an AMI. For more information, see [Step 1: Choose an Amazon Machine Image \(AMI\) \(p. 562\)](#).
5. On the **Choose an Instance Type** page, select the hardware configuration and size of the instance to launch, and then choose Next: Configure Instance Details. For more information, see [Step 2: Choose an Instance Type \(p. 563\)](#).
6. On the **Configure Instance Details** page, configure the Spot Instance request as follows:
 - **Number of instances:** Enter the number of instances to launch.

Note

Amazon EC2 creates a separate request for each Spot Instance.

- (Optional) To help ensure that you maintain the correct number of instances to handle demand on your application, you can choose **Launch into Auto Scaling Group** to create a launch configuration and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).
- **Purchasing option:** Choose **Request Spot instances** to launch a Spot Instance. When you choose this option, the following fields appear.
- **Current price:** The current Spot price in each Availability Zone is displayed for the instance type that you selected.
- (Optional) **Maximum price:** You can leave the field empty, or you can specify the maximum amount you're willing to pay.

Warning

If you specify a maximum price, your instances will be interrupted more frequently than if you leave the field empty.

- If you specify a maximum price that is less than the Spot price, your Spot Instance will not launched.
- If you specify a maximum price that is more than the current Spot price, your Spot Instance will launch and be charged at the current Spot price. After your Spot Instance is running, if the Spot price rises above your maximum price, Amazon EC2 interrupts your Spot Instance.
- Regardless of the maximum price you specify, you will always be charged the current Spot price.
- If you leave the field empty, you'll pay the current Spot price.

- **Persistent request:** Choose **Persistent request** to resubmit the Spot Instance request if your Spot Instance is interrupted.
- **Interruption behavior:** By default, the Spot service terminates a Spot Instance when it is interrupted. If you choose **Persistent request**, you can then specify that the Spot service stops or hibernates your Spot Instance when it's interrupted. For more information, see [Interruption behavior \(p. 434\)](#).
- (Optional) **Request valid to:** Choose **Edit** to specify when the Spot Instance request expires.

For more information about configuring your Spot Instance, see [Step 3: Configure Instance Details \(p. 563\)](#).

7. The AMI you selected includes one or more volumes of storage, including the root device volume. On the **Add Storage** page, you can specify additional volumes to attach to the instance by choosing **Add New Volume**. For more information, see [Step 4: Add Storage \(p. 566\)](#).
8. On the **Add Tags** page, specify [tags \(p. 2085\)](#) by providing key and value combinations. For more information, see [Step 5: Add Tags \(p. 566\)](#).
9. On the **Configure Security Group** page, use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. (For more information about security groups, see [Amazon EC2 security groups for Windows instances \(p. 1674\)](#).) Select or create a security group, and then choose **Review and Launch**. For more information, see [Step 6: Configure Security Group \(p. 566\)](#).
10. On the **Review Instance Launch** page, check the details of your instance, and make any necessary changes by choosing the appropriate **Edit** link. When you are ready, choose **Launch**. For more information, see [Step 7: Review Instance Launch and Select Key Pair \(p. 567\)](#).
11. In the **Select an existing key pair or create a new key pair** dialog box, you can choose an existing key pair, or create a new one. For example, choose **Choose an existing key pair**, then select the key pair that you created when getting set up. For more information, see [Amazon EC2 key pairs and Windows instances \(p. 1662\)](#).

Important

If you choose the **Proceed without key pair** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

12. To launch your instance, select the acknowledgment check box, then choose **Launch Instances**.

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 2114\)](#).

AWS CLI

To create a Spot Instance request using [run-instances](#)

Use the [run-instances](#) command and specify the Spot Instance options in the `--instance-market-options` parameter.

```
aws ec2 run-instances \
--image-id ami-0abcdef1234567890 \
--instance-type t2.micro \
--count 5 \
--subnet-id subnet-08fc749671b2d077c \
--key-name MyKeyPair \
--security-group-ids sg-0b0384b66d7d692f9 \
--instance-market-options file://spot-options.json
```

The following is the data structure to specify in the JSON file for `--instance-market-options`. You can also specify `ValidUntil` and `InstanceInterruptionBehavior`. If you do not specify a field in the data structure, the default value is used.

The following example creates a persistent request.

```
{  
    "MarketType": "spot",  
    "SpotOptions": {  
        "SpotInstanceType": "persistent"  
    }  
}
```

To create a Spot Instance request using [request-spot-instances](#)

Note

We strongly discourage using the [request-spot-instances](#) command to request a Spot Instance because it is a legacy API with no planned investment. For more information, see [Which is the best Spot request method to use? \(p. 399\)](#)

Use the [request-spot-instances](#) command to create a one-time request.

```
aws ec2 request-spot-instances \  
    --instance-count 5 \  
    --type "one-time" \  
    --launch-specification file://specification.json
```

Use the [request-spot-instances](#) command to create a persistent request.

```
aws ec2 request-spot-instances \  
    --instance-count 5 \  
    --type "persistent" \  
    --launch-specification file://specification.json
```

For example launch specification files to use with these commands, see [Spot Instance request example launch specifications \(p. 421\)](#). If you download a launch specification file from the Spot Requests console, you must use the [request-spot-fleet](#) command instead (the Spot Requests console specifies a Spot Instance request using a Spot Fleet).

Find running Spot Instances

Amazon EC2 launches a Spot Instance when capacity is available. A Spot Instance runs until it is interrupted or you terminate it yourself.

To find running Spot Instances (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests**. You can see both Spot Instance requests and Spot Fleet requests. If a Spot Instance request has been fulfilled, **Capacity** is the ID of the Spot Instance. For a Spot Fleet, **Capacity** indicates how much of the requested capacity has been fulfilled. To view the IDs of the instances in a Spot Fleet, choose the expand arrow, or select the fleet and choose **Instances**.

Note

For Spot Instance requests that are created by a Spot Fleet, the requests are not tagged instantly with the system tag that indicates the Spot Fleet to which they belong, and for a period of time may appear separate from Spot Fleet request.

Alternatively, in the navigation pane, choose **Instances**. In the top right corner, choose the settings icon (), and then under **Attribute columns**, select **Instance lifecycle**. For each instance, **Instance lifecycle** is either normal, spot, or scheduled.

To find running Spot Instances (AWS CLI)

To enumerate your Spot Instances, use the [describe-spot-instance-requests](#) command with the `--query` option.

```
aws ec2 describe-spot-instance-requests \
--query "SpotInstanceRequests[*].{ID:InstanceId}"
```

The following is example output:

```
[  
  {  
    "ID": "i-1234567890abcdef0"  
  },  
  {  
    "ID": "i-0598c7d356eba48d7"  
  }  
]
```

Alternatively, you can enumerate your Spot Instances using the [describe-instances](#) command with the `--filters` option.

```
aws ec2 describe-instances \
--filters "Name=instance-lifecycle,Values=spot"
```

To describe a single Spot Instance instance, use the [describe-spot-instance-requests](#) command with the `--spot-instance-request-ids` option.

```
aws ec2 describe-spot-instance-requests \
--spot-instance-request-ids sir-08b93456
```

Tag Spot Instance requests

To help categorize and manage your Spot Instance requests, you can tag them with custom metadata. You can assign a tag to a Spot Instance request when you create it, or afterward. You can assign tags using the Amazon EC2 console or a command line tool.

When you tag a Spot Instance request, the instances and volumes that are launched by the Spot Instance request are not automatically tagged. You need to explicitly tag the instances and volumes launched by the Spot Instance request. You can assign a tag to a Spot Instance and volumes during launch, or afterward.

For more information about how tags work, see [Tag your Amazon EC2 resources \(p. 2085\)](#).

Contents

- [Prerequisites \(p. 414\)](#)
- [Tag a new Spot Instance request \(p. 415\)](#)
- [Tag an existing Spot Instance request \(p. 416\)](#)

- [View Spot Instance request tags \(p. 416\)](#)

Prerequisites

Grant the user the permission to tag resources. For more information about IAM policies and example policies, see [Example: Tag resources \(p. 1631\)](#).

The IAM policy you create is determined by which method you use for creating a Spot Instance request.

- If you use the launch instance wizard or `run-instances` to request Spot Instances, see [To grant a user the permission to tag resources when using the launch instance wizard or run-instances](#).
- If you use the `request-spot-instances` command to request Spot Instances, see [To grant a user the permission to tag resources when using request-spot-instances](#).

To grant a user the permission to tag resources when using the launch instance wizard or run-instances

Create a IAM policy that includes the following:

- The `ec2:RunInstances` action. This grants the user permission to launch an instance.
- For `Resource`, specify `spot-instances-request`. This allows users to create Spot Instance requests, which request Spot Instances.
- The `ec2:CreateTags` action. This grants the user permission to create tags.
- For `Resource`, specify `*`. This allows users to tag all resources that are created during instance launch.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "AllowLaunchInstances",  
            "Effect": "Allow",  
            "Action": [  
                "ec2:RunInstances"  
            ],  
            "Resource": [  
                "arn:aws:ec2:us-east-1::image/*",  
                "arn:aws:ec2:us-east-1::subnet/*",  
                "arn:aws:ec2:us-east-1::network-interface/*",  
                "arn:aws:ec2:us-east-1::security-group/*",  
                "arn:aws:ec2:us-east-1::key-pair/*",  
                "arn:aws:ec2:us-east-1::volume/*",  
                "arn:aws:ec2:us-east-1::instance/*",  
                "arn:aws:ec2:us-east-1::spot-instances-request/*"  
            ]  
        },  
        {  
            "Sid": "TagSpotInstanceRequests",  
            "Effect": "Allow",  
            "Action": "ec2:CreateTags",  
            "Resource": "*"  
        }  
    ]  
}
```

Note

When you use the `RunInstances` action to create Spot Instance requests and tag the Spot Instance requests on create, you need to be aware of how Amazon EC2 evaluates the `spot-instances-request` resource in the `RunInstances` statement.

The `spot-instances-request` resource is evaluated in the IAM policy as follows:

- If you don't tag a Spot Instance request on create, Amazon EC2 does not evaluate the `spot-instances-request` resource in the `RunInstances` statement.
- If you tag a Spot Instance request on create, Amazon EC2 evaluates the `spot-instances-request` resource in the `RunInstances` statement.

Therefore, for the `spot-instances-request` resource, the following rules apply to the IAM policy:

- If you use `RunInstances` to create a Spot Instance request and you don't intend to tag the Spot Instance request on create, you don't need to explicitly allow the `spot-instances-request` resource; the call will succeed.
- If you use `RunInstances` to create a Spot Instance request and intend to tag the Spot Instance request on create, you must include the `spot-instances-request` resource in the `RunInstances` allow statement, otherwise the call will fail.
- If you use `RunInstances` to create a Spot Instance request and intend to tag the Spot Instance request on create, you must specify the `spot-instances-request` resource or include a * wildcard in the `CreateTags` allow statement, otherwise the call will fail.

For example IAM policies, including policies that are not supported for Spot Instance requests, see [Work with Spot Instances \(p. 1626\)](#).

To grant a user the permission to tag resources when using `request-spot-instances`

Create a IAM policy that includes the following:

- The `ec2:RequestSpotInstances` action. This grants the user permission to create a Spot Instance request.
- The `ec2:CreateTags` action. This grants the user permission to create tags.
- For `Resource`, specify `spot-instances-request`. This allows users to tag only the Spot Instance request.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "TagSpotInstanceRequest",  
            "Effect": "Allow",  
            "Action": [  
                "ec2:RequestSpotInstances",  
                "ec2:CreateTags"  
            ],  
            "Resource": "arn:aws:ec2:us-east-1:111122223333:spot-instances-request/*"  
        }  
    ]  
}
```

Tag a new Spot Instance request

To tag a new Spot Instance request using the console

1. Follow the [Create a Spot Instance request \(p. 407\)](#) procedure.
2. To add a tag, on the **Add Tags** page, choose **Add Tag**, and enter the key and value for the tag. Choose **Add another tag** for each additional tag.

For each tag, you can tag the Spot Instance request, the Spot Instances, and the volumes with the same tag. To tag all three, ensure that **Instances**, **Volumes**, and **Spot Instance Requests** are

selected. To tag only one or two, ensure that the resources you want to tag are selected, and the other resources are cleared.

3. Complete the required fields to create a Spot Instance request, and then choose **Launch**. For more information, see [Create a Spot Instance request \(p. 407\)](#).

To tag a new Spot Instance request using the AWS CLI

To tag a Spot Instance request when you create it, configure the Spot Instance request configuration as follows:

- Specify the tags for the Spot Instance request using the `--tag-specification` parameter.
- For `ResourceType`, specify `spot-instances-request`. If you specify another value, the Spot Instance request will fail.
- For `Tags`, specify the key-value pair. You can specify more than one key-value pair.

In the following example, the Spot Instance request is tagged with two tags: `Key=Environment` and `Value=Production`, and `Key=Cost-Center` and `Value=123`.

```
aws ec2 request-spot-instances \
--instance-count 5 \
--type "one-time" \
--launch-specification file://specification.json \
--tag-specification 'ResourceType=spot-instances-
request,Tags=[{Key=Environment,Value=Production},{Key=Cost-Center,Value=123}]'
```

Tag an existing Spot Instance request

To tag an existing Spot Instance request using the console

After you have created a Spot Instance request, you can add tags to the Spot Instance request using the console.

Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

1. In the navigation pane, choose **Spot Requests**.
2. Select your Spot Instance request.
3. Choose the **Tags** tab and choose **Create Tag**.

To tag an existing Spot Instance using the console

After your Spot Instance request has launched your Spot Instance, you can add tags to the instance using the console. For more information, see [Add and delete tags on an individual resource \(p. 2091\)](#).

To tag an existing Spot Instance request or Spot Instance using the AWS CLI

Use the `create-tags` command to tag existing resources. In the following example, the existing Spot Instance request and the Spot Instance are tagged with `Key=purpose` and `Value=test`.

```
aws ec2 create-tags \
--resources sir-08b93456 i-1234567890abcdef0 \
--tags Key=purpose,Value=test
```

View Spot Instance request tags

To view Spot Instance request tags using the console

Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

1. In the navigation pane, choose **Spot Requests**.
2. Select your Spot Instance request and choose the **Tags** tab.

To describe Spot Instance request tags

Use the [describe-tags](#) command to view the tags for the specified resource. In the following example, you describe the tags for the specified request.

```
aws ec2 describe-tags \
--filters "Name=resource-id,Values=sir-11112222-3333-4444-5555-66666EXAMPLE"
```

```
{  
    "Tags": [  
        {  
            "Key": "Environment",  
            "ResourceId": "sir-11112222-3333-4444-5555-66666EXAMPLE",  
            "ResourceType": "spot-instances-request",  
            "Value": "Production"  
        },  
        {  
            "Key": "Another key",  
            "ResourceId": "sir-11112222-3333-4444-5555-66666EXAMPLE",  
            "ResourceType": "spot-instances-request",  
            "Value": "Another value"  
        }  
    ]  
}
```

You can also view the tags of a Spot Instance request by describing the Spot Instance request.

Use the [describe-spot-instance-requests](#) command to view the configuration of the specified Spot Instance request, which includes any tags that were specified for the request.

```
aws ec2 describe-spot-instance-requests \
--spot-instance-request-ids sir-11112222-3333-4444-5555-66666EXAMPLE
```

```
{  
    "SpotInstanceRequests": [  
        {  
            "CreateTime": "2020-06-24T14:22:11+00:00",  
            "InstanceId": "i-1234567890EXAMPLE",  
            "LaunchSpecification": {  
                "SecurityGroups": [  
                    {  
                        "GroupName": "launch-wizard-6",  
                        "GroupId": "sg-1234567890EXAMPLE"  
                    }  
                ],  
                "BlockDeviceMappings": [  
                    {  
                        "DeviceName": "/dev/xvda",  
                        "Ebs": {  
                            "DeleteOnTermination": true,  
                            "VolumeSize": 8,  
                            "VolumeType": "gp2"  
                        }  
                    }  
                ],  
                "ImageId": "ami-1234567890EXAMPLE",  
                "InstanceType": "t2.micro",

"InstanceInterruptionBehavior": "terminate"
}
]
}
```

Cancel a Spot Instance request

If you no longer want your Spot Instance request, you can cancel it. You can only cancel Spot Instance requests that are open, active, or disabled.

- Your Spot Instance request is **open** when your request has not yet been fulfilled and no instances have been launched.
- Your Spot Instance request is **active** when your request has been fulfilled and Spot Instances have launched as a result.
- Your Spot Instance request is **disabled** when you stop your Spot Instance.

If your Spot Instance request is active and has an associated running Spot Instance, canceling the request does not terminate the instance. For more information about terminating a Spot Instance, see [Terminate a Spot Instance \(p. 420\)](#).

To cancel a Spot Instance request (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests** and select the Spot Instance request.

3. Choose **Actions, Cancel request**.
4. (Optional) If you are finished with the associated Spot Instances, you can terminate them. In the **Cancel Spot request** dialog box, select **Terminate instances**, and then choose **Confirm**.

To cancel a Spot Instance request (AWS CLI)

- Use the [cancel-spot-instance-requests](#) command to cancel the specified Spot Instance request.

```
aws ec2 cancel-spot-instance-requests --spot-instance-request-ids sir-08b93456
```

Stop a Spot Instance

If you don't need your Spot Instances now, but you want to restart them later without losing the data persisted in the Amazon EBS volume, you can stop them. The steps for stopping a Spot Instance are similar to the steps for stopping an On-Demand Instance.

Note

While a Spot Instance is stopped, you can modify some of its instance attributes, but not the instance type.

We don't charge usage for a stopped Spot Instance, or data transfer fees, but we do charge for the storage for any Amazon EBS volumes.

Limitations

- You can only stop a Spot Instance if the Spot Instance was launched from a persistent Spot Instance request.
- You can't stop a Spot Instance if the associated Spot Instance request is cancelled. When the Spot Instance request is cancelled, you can only terminate the Spot Instance.
- You can't stop a Spot Instance if it is part of a fleet or launch group, or Availability Zone group.

Console

To stop a Spot Instance (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the Spot Instance.
3. Choose **Instance state, Stop instance**.
4. When prompted for confirmation, choose **Stop**.

AWS CLI

To stop a Spot Instance (AWS CLI)

- Use the [stop-instances](#) command to manually stop one or more Spot Instances.

```
aws ec2 stop-instances --instance-ids i-1234567890abcdef0
```

Start a Spot Instance

You can start a Spot Instance that you previously stopped. The steps for starting a Spot Instance are similar to the steps for starting an On-Demand Instance.

Prerequisites

You can only start a Spot Instance if:

- You manually stopped the Spot Instance.
- The Spot Instance is an EBS-backed instance.
- Spot Instance capacity is available.
- The Spot price is lower than your maximum price.

Limitations

- You can't start a Spot Instance if it is part of fleet or launch group, or Availability Zone group.

Console

To start a Spot Instance (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select the Spot Instance.
3. Choose **Instance state, Start instance**.

AWS CLI

To start a Spot Instance (AWS CLI)

- Use the [start-instances](#) command to manually start one or more Spot Instances.

```
aws ec2 start-instances --instance-ids i-1234567890abcdef0
```

Terminate a Spot Instance

If you terminate a running or stopped Spot Instance that was launched by a persistent Spot Instance request, the Spot Instance request transitions to the open state so that a new Spot Instance can be launched. To ensure that no new Spot Instance is launched, you must first cancel the Spot Instance request.

If you cancel an active Spot Instance request that has a running Spot Instance, the running Spot Instance is not automatically terminated; you must manually terminate the Spot Instance.

If you cancel a disabled Spot Instance request that has a stopped Spot Instance, the stopped Spot Instance is automatically terminated by the Amazon EC2 Spot service. There might be a short lag between when you cancel the Spot Instance request and when the Spot service terminates the Spot Instance.

For information about canceling a Spot Instance request, see [Cancel a Spot Instance request \(p. 418\)](#).

Console

To manually terminate a Spot Instance using the console

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.

2. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
3. In the navigation pane, choose **Instances**.
4. To confirm that the instance is a Spot Instance, check that **spot** appears in the **Instance lifecycle** column.
5. Select the instance, and choose **Instance state**, **Terminate instance**.
6. Choose **Terminate** when prompted for confirmation.

AWS CLI

To manually terminate a Spot Instance using the AWS CLI

- Use the [terminate-instances](#) command to manually terminate Spot Instances.

```
aws ec2 terminate-instances --instance-ids i-1234567890abcdef0 i-0598c7d356eba48d7
```

Spot Instance request example launch specifications

The following examples show launch configurations that you can use with the [request-spot-instances](#) command to create a Spot Instance request. For more information, see [Create a Spot Instance request \(p. 407\)](#).

Note

We strongly discourage using the [request-spot-instances](#) command to request a Spot Instance because it is a legacy API with no planned investment. For more information, see [Which is the best Spot request method to use? \(p. 399\)](#)

Examples

- [Example 1: Launch Spot Instances \(p. 421\)](#)
- [Example 2: Launch Spot Instances in the specified Availability Zone \(p. 421\)](#)
- [Example 3: Launch Spot Instances in the specified subnet \(p. 422\)](#)
- [Example 4: Launch a Dedicated Spot Instance \(p. 422\)](#)

Example 1: Launch Spot Instances

The following example does not include an Availability Zone or subnet. Amazon EC2 selects an Availability Zone for you. Amazon EC2 launches the instances in the default subnet of the selected Availability Zone.

```
{  
    "ImageId": "ami-0abcdef1234567890",  
    "KeyName": "my-key-pair",  
    "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],  
    "InstanceType": "m5.medium",  
    "IamInstanceProfile": {  
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"  
    }  
}
```

Example 2: Launch Spot Instances in the specified Availability Zone

The following example includes an Availability Zone. Amazon EC2 launches the instances in the default subnet of the specified Availability Zone.

```
{  
    "ImageId": "ami-0abcdef1234567890",  
    "KeyName": "my-key-pair",  
    "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],  
    "InstanceType": "m5.medium",  
    "Placement": {  
        "AvailabilityZone": "us-west-2a"  
    },  
    "IamInstanceProfile": {  
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"  
    }  
}
```

Example 3: Launch Spot Instances in the specified subnet

The following example includes a subnet. Amazon EC2 launches the instances in the specified subnet. If the VPC is a nondefault VPC, the instance does not receive a public IPv4 address by default.

```
{  
    "ImageId": "ami-0abcdef1234567890",  
    "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],  
    "InstanceType": "m5.medium",  
    "SubnetId": "subnet-1a2b3c4d",  
    "IamInstanceProfile": {  
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"  
    }  
}
```

To assign a public IPv4 address to an instance in a nondefault VPC, specify the `AssociatePublicIpAddress` field as shown in the following example. When you specify a network interface, you must include the subnet ID and security group ID using the network interface, rather than using the `SubnetId` and `SecurityGroupIds` fields shown in the previous code block.

```
{  
    "ImageId": "ami-0abcdef1234567890",  
    "KeyName": "my-key-pair",  
    "InstanceType": "m5.medium",  
    "NetworkInterfaces": [  
        {  
            "DeviceIndex": 0,  
            "SubnetId": "subnet-1a2b3c4d5e6f7g8h9",  
            "Groups": [ "sg-1a2b3c4d5e6f7g8h9" ],  
            "AssociatePublicIpAddress": true  
        }  
    ],  
    "IamInstanceProfile": {  
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"  
    }  
}
```

Example 4: Launch a Dedicated Spot Instance

The following example requests Spot Instance with a tenancy of dedicated. A Dedicated Spot Instance must be launched in a VPC.

```
{  
    "ImageId": "ami-0abcdef1234567890",  
    "KeyName": "my-key-pair",  
    "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],  
    "InstanceType": "c5.8xlarge",  
    "Tenancy": "dedicated"  
}
```

```

    "SubnetId": "subnet-1a2b3c4d5e6f7g8h9",
    "Placement": {
        "Tenancy": "dedicated"
    }
}

```

Spot request status

To help you track your Spot Instance requests and plan your use of Spot Instances, use the request status provided by Amazon EC2. For example, the request status can provide the reason why your Spot request isn't fulfilled yet, or list the constraints that are preventing the fulfillment of your Spot request.

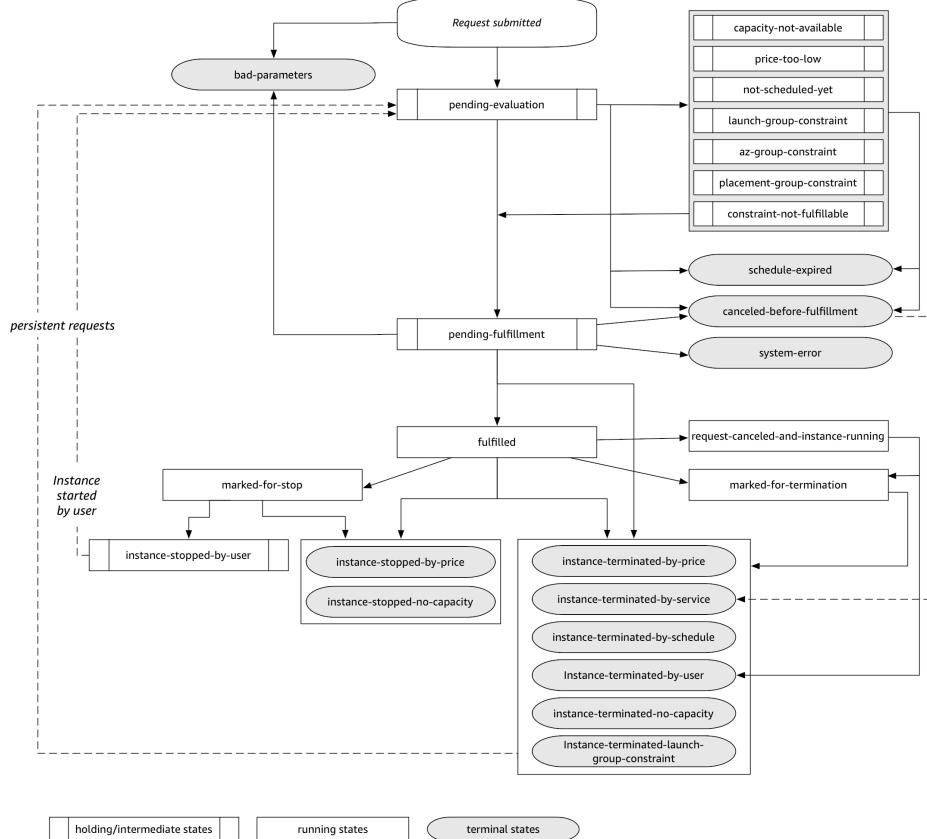

At each step of the process—also called the Spot request *lifecycle*—specific events determine successive request states.

Contents

- [Lifecycle of a Spot request \(p. 423\)](#)
- [Get request status information \(p. 426\)](#)
- [Spot request status codes \(p. 427\)](#)
- [EC2 Spot Instance Request Fulfillment event \(p. 429\)](#)

Lifecycle of a Spot request

The following diagram shows you the paths that your Spot request can follow throughout its lifecycle, from submission to termination. Each step is depicted as a node, and the status code for each node describes the status of the Spot request and Spot Instance.

Pending evaluation

As soon as you create a Spot Instance request, it goes into the pending-evaluation state unless one or more request parameters are not valid (bad-parameters).

Status code	Request state	Instance state
pending-evaluation	open	Not applicable
bad-parameters	closed	Not applicable

Holding

If one or more request constraints are valid but can't be met yet, or if there is not enough capacity, the request goes into a holding state waiting for the constraints to be met. The request options affect the likelihood of the request being fulfilled. For example, if there is no capacity, your request stays in a holding state until there is available capacity. If you specify an Availability Zone group, the request stays in a holding state until the Availability Zone constraint is met.

In the event of an outage of one of the Availability Zones, there is a chance that the spare EC2 capacity available for Spot Instance requests in other Availability Zones can be affected.

Status code	Request state	Instance state
capacity-not-available	open	Not applicable
price-too-low	open	Not applicable
not-scheduled-yet	open	Not applicable
launch-group-constraint	open	Not applicable
az-group-constraint	open	Not applicable
placement-group-constraint	open	Not applicable
constraint-not-fulfillable	open	Not applicable

Pending evaluation/fulfillment-terminal

Your Spot Instance request can go to a terminal state if you create a request that is valid only during a specific time period and this time period expires before your request reaches the pending fulfillment phase. It might also happen if you cancel the request, or if a system error occurs.

Status code	Request state	Instance state
schedule-expired	cancelled	Not applicable
canceled-before-fulfillment ¹	cancelled	Not applicable
bad-parameters	failed	Not applicable
system-error	closed	Not applicable

¹ If you cancel the request.

Pending fulfillment

When the constraints you specified (if any) are met, your Spot request goes into the pending-fulfillment state.

At this point, Amazon EC2 is getting ready to provision the instances that you requested. If the process stops at this point, it is likely to be because it was canceled by the user before a Spot Instance was launched. It might also be because an unexpected system error occurred.

Status code	Request state	Instance state
pending-fulfillment	open	Not applicable

Fulfilled

When all the specifications for your Spot Instances are met, your Spot request is fulfilled. Amazon EC2 launches the Spot Instances, which can take a few minutes. If a Spot Instance is hibernated or stopped when interrupted, it remains in this state until the request can be fulfilled again or the request is canceled.

Status code	Request state	Instance state
fulfilled	active	pending → running
fulfilled	active	stopped → running

If you stop a Spot Instance, your Spot request goes into the marked-for-stop or instance-stopped-by-user state until the Spot Instance can be started again or the request is cancelled.

Status code	Request state	Instance state
marked-for-stop	active	stopping
instance-stopped-by-user ¹	disabled or cancelled ²	stopped

¹ A Spot Instance goes into the instance-stopped-by-user state if you stop the instance or run the shutdown command from the instance. After you've stopped the instance, you can start it again. On restart, the Spot Instance request returns to the pending-evaluation state and then Amazon EC2 launches a new Spot Instance when the constraints are met.

² The Spot request state is disabled if you stop the Spot Instance but do not cancel the request. The request state is cancelled if your Spot Instance is stopped and the request expires.

Fulfilled-terminal

Your Spot Instances continue to run as long as there is available capacity for your instance type, and you don't terminate the instance. If Amazon EC2 must terminate your Spot Instances, the Spot request goes into a terminal state. A request also goes into the terminal state if you cancel the Spot request or terminate the Spot Instances.

Status code	Request state	Instance state
request-canceled-and-instance-running	cancelled	running
marked-for-stop	active	running
marked-for-termination	active	running
instance-stopped-by-price	disabled	stopped
instance-stopped-by-user	disabled	stopped
instance-stopped-no-capacity	disabled	stopped
instance-terminated-by-price	closed (one-time), open (persistent)	terminated
instance-terminated-by-schedule	closed	terminated
instance-terminated-by-service	cancelled	terminated
instance-terminated-by-user	closed or cancelled ¹	terminated
instance-terminated-no-capacity	closed (one-time), open (persistent)	running †
instance-terminated-no-capacity	closed (one-time), open (persistent)	terminated
instance-terminated-launch-group-constraint	closed (one-time), open (persistent)	terminated

¹ The request state is *closed* if you terminate the instance but do not cancel the request. The request state is *cancelled* if you terminate the instance and cancel the request. Even if you terminate a Spot Instance before you cancel its request, there might be a delay before Amazon EC2 detects that your Spot Instance was terminated. In this case, the request state can either be *closed* or *cancelled*.

† When Amazon EC2 interrupts a Spot Instance if it needs the capacity back *and* the instance is configured to *terminate* on interruption, the status is immediately set to *instance-terminated-no-capacity* (it is not set to *marked-for-termination*). However, the instance remains in the *running* state for 2 minutes to reflect the 2-minute period when the instance receives the Spot Instance interruption notice. After 2 minutes, the instance state is set to *terminated*.

Persistent requests

When your Spot Instances are terminated (either by you or Amazon EC2), if the Spot request is a persistent request, it returns to the pending-evaluation state and then Amazon EC2 can launch a new Spot Instance when the constraints are met.

Get request status information

You can get request status information using the AWS Management Console or a command line tool.

To get request status information (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests** and select the Spot request.
3. To check the status, on the **Description** tab, check the **Status** field.

To get request status information using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [describe-spot-instance-requests](#) (AWS CLI)
- [Get-EC2SpotInstanceRequest](#) (AWS Tools for Windows PowerShell)

Spot request status codes

Spot request status information is composed of a status code, the update time, and a status message. Together, these help you determine the disposition of your Spot request.

The following are the Spot request status codes:

az-group-constraint

Amazon EC2 cannot launch all the instances you requested in the same Availability Zone.

bad-parameters

One or more parameters for your Spot request are not valid (for example, the AMI you specified does not exist). The status message indicates which parameter is not valid.

canceled-before-fulfillment

The user canceled the Spot request before it was fulfilled.

capacity-not-available

There is not enough capacity available for the instances that you requested.

constraint-not-fulfillable

The Spot request can't be fulfilled because one or more constraints are not valid (for example, the Availability Zone does not exist). The status message indicates which constraint is not valid.

fulfilled

The Spot request is active, and Amazon EC2 is launching your Spot Instances.

instance-stopped-by-price

Your instance was stopped because the Spot price exceeded your maximum price.

instance-stopped-by-user

Your instance was stopped because a user stopped the instance or ran the shutdown command from the instance.

instance-stopped-no-capacity

Your instance was stopped due to EC2 capacity management needs.

instance-terminated-by-price

Your instance was terminated because the Spot price exceeded your maximum price. If your request is persistent, the process restarts, so your request is pending evaluation.

instance-terminated-by-schedule

Your Spot Instance was terminated at the end of its scheduled duration.

instance-terminated-by-service

Your instance was terminated from a stopped state.

instance-terminated-by-user or spot-instance-terminated-by-user

You terminated a Spot Instance that had been fulfilled, so the request state is closed (unless it's a persistent request) and the instance state is terminated.

instance-terminated-launch-group-constraint

One or more of the instances in your launch group was terminated, so the launch group constraint is no longer fulfilled.

instance-terminated-no-capacity

Your instance was terminated due to standard capacity management processes.

launch-group-constraint

Amazon EC2 cannot launch all the instances that you requested at the same time. All instances in a launch group are started and terminated together.

limit-exceeded

The limit on the number of EBS volumes or total volume storage was exceeded. For more information about these limits and how to request an increase, see [Amazon EBS Limits](#) in the *Amazon Web Services General Reference*.

marked-for-stop

The Spot Instance is marked for stopping.

marked-for-termination

The Spot Instance is marked for termination.

not-scheduled-yet

The Spot request is not evaluated until the scheduled date.

pending-evaluation

After you make a Spot Instance request, it goes into the pending-evaluation state while the system evaluates the parameters of your request.

pending-fulfillment

Amazon EC2 is trying to provision your Spot Instances.

placement-group-constraint

The Spot request can't be fulfilled yet because a Spot Instance can't be added to the placement group at this time.

price-too-low

The request can't be fulfilled yet because your maximum price is below the Spot price. In this case, no instance is launched and your request remains open.

request-canceled-and-instance-running

You canceled the Spot request while the Spot Instances are still running. The request is cancelled, but the instances remain running.

schedule-expired

The Spot request expired because it was not fulfilled before the specified date.

system-error

There was an unexpected system error. If this is a recurring issue, please contact AWS Support for assistance.

EC2 Spot Instance Request Fulfillment event

When a Spot Instance request is fulfilled, Amazon EC2 sends an EC2 Spot Instance Request Fulfillment event to Amazon EventBridge. You can create a rule to take an action whenever this event occurs, such as invoking a Lambda function or notifying an Amazon SNS topic.

The following is example data for this event.

```
{  
    "version": "0",  
    "id": "01234567-1234-0123-1234-012345678901",  
    "detail-type": "EC2 Spot Instance Request Fulfillment",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "yyyy-mm-ddThh:mm:ssZ",  
    "region": "us-east-2",  
    "resources": ["arn:aws:ec2:us-east-2:123456789012:instance/i-1234567890abcdef0"],  
    "detail": {  
        "spot-instance-request-id": "sir-1a2b3c4d",  
        "instance-id": "i-1234567890abcdef0"  
    }  
}
```

For more information, see the [Amazon EventBridge User Guide](#).

EC2 instance rebalance recommendations

An EC2 instance *rebalance recommendation* is a signal that notifies you when a Spot Instance is at elevated risk of interruption. The signal can arrive sooner than the [two-minute Spot Instance interruption notice \(p. 440\)](#), giving you the opportunity to proactively manage the Spot Instance. You can decide to rebalance your workload to new or existing Spot Instances that are not at an elevated risk of interruption.

It is not always possible for Amazon EC2 to send the rebalance recommendation signal before the two-minute Spot Instance interruption notice. Therefore, the rebalance recommendation signal can arrive along with the two-minute interruption notice.

Rebalance recommendations are made available as a EventBridge event and as an item in the [instance metadata \(p. 862\)](#) on the Spot Instance. Events are emitted on a best effort basis.

Note

Rebalance recommendations are only supported for Spot Instances that are launched after November 5, 2020 00:00 UTC.

Topics

- [Rebalance actions you can take \(p. 430\)](#)
- [Monitor rebalance recommendation signals \(p. 430\)](#)
- [Services that use the rebalance recommendation signal \(p. 432\)](#)

Rebalance actions you can take

These are some of the possible rebalancing actions that you can take:

Graceful shutdown

When you receive the rebalance recommendation signal for a Spot Instance, you can start your instance shutdown procedures, which might include ensuring that processes are completed before stopping them. For example, you can upload system or application logs to Amazon Simple Storage Service (Amazon S3), you can shut down Amazon SQS workers, or you can complete deregistration from the Domain Name System (DNS). You can also save your work in external storage and resume it at a later time.

Prevent new work from being scheduled

When you receive the rebalance recommendation signal for a Spot Instance, you can prevent new work from being scheduled on the instance, while continuing to use the instance until the scheduled work is completed.

Proactively launch new replacement instances

You can configure Auto Scaling groups, EC2 Fleet, or Spot Fleet to automatically launch replacement Spot Instances when a rebalance recommendation signal is emitted. For more information, see [Use Capacity Rebalancing to handle Amazon EC2 Spot interruptions](#) in the *Amazon EC2 Auto Scaling User Guide*, and [Capacity Rebalancing \(p. 1001\)](#) for EC2 Fleet and [Capacity Rebalancing \(p. 1044\)](#) for Spot Fleet in this user guide.

Monitor rebalance recommendation signals

You can monitor the rebalance recommendation signal so that, when it is emitted, you can take the actions that are specified in the preceding section. The rebalance recommendation signal is made available as an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events) and as instance metadata on the Spot Instance.

Monitor rebalance recommendation signals:

- [Use Amazon EventBridge \(p. 430\)](#)
- [Use instance metadata \(p. 432\)](#)

Use Amazon EventBridge

When the rebalance recommendation signal is emitted for a Spot Instance, the event for the signal is sent to Amazon EventBridge. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes a target (or targets) specified in the rule.

The following is an example event for the rebalance recommendation signal.

```
{  
    "version": "0",  
    "id": "12345678-1234-1234-1234-123456789012",  
    "detail-type": "EC2 Instance Rebalance Recommendation",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "yyyy-mm-ddThh:mm:ssZ",  
    "region": "us-east-2",  
    "resources": ["arn:aws:ec2:us-east-2:123456789012:instance/i-1234567890abcdef0"],  
    "detail": {  
        "instance-id": "i-1234567890abcdef0"  
    }  
}
```

The following fields form the event pattern that is defined in the rule:

"detail-type": "EC2 Instance Rebalance Recommendation"

Identifies that the event is a rebalance recommendation event

"source": "aws.ec2"

Identifies that the event is from Amazon EC2

Create an EventBridge rule

You can write an EventBridge rule and automate what actions to take when the event pattern matches the rule.

The following example creates an EventBridge rule to send an email, text message, or mobile push notification every time Amazon EC2 emits a rebalance recommendation signal. The signal is emitted as an EC2 Instance Rebalance Recommendation event, which triggers the action defined by the rule.

Before creating the EventBridge rule, you must create the Amazon SNS topic for the email, text message, or mobile push notification.

To create an EventBridge rule for a rebalance recommendation event

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. Choose **Create rule**.
3. For **Define rule detail**, do the following:
 - a. Enter a **Name** for the rule, and, optionally, a description.
A rule can't have the same name as another rule in the same Region and on the same event bus.
 - b. For **Event bus**, choose **default**. When an AWS service in your account generates an event, it always goes to your account's default event bus.
 - c. For **Rule type**, choose **Rule with an event pattern**.
 - d. Choose **Next**.
4. For **Build event pattern**, do the following:
 - a. For **Event source**, choose **AWS events or EventBridge partner events**.
 - b. For **Event pattern**, for this example you'll specify the following event pattern to match the EC2 Instance Rebalance Recommendation event, and then choose **Save**.

```
{  
  "source": ["aws.ec2"],  
  "detail-type": ["EC2 Instance Rebalance Recommendation"]  
}
```

To add the event pattern, you can either use a template by choosing **Event pattern form**, or specify your own pattern by choosing **Custom pattern (JSON editor)**, as follows:

- i. To use a template to create the event pattern, do the following:
 - A. Choose **Event pattern form**.
 - B. For **Event source**, choose **AWS services**.
 - C. For **AWS Service**, choose **EC2 Spot Fleet**.
 - D. For **Event type**, choose **EC2 Instance Rebalance Recommendation**.
 - E. To customize the template, choose **Edit pattern** and make your changes to match the example event pattern.

- ii. (Alternative) To specify a custom event pattern, do the following:
 - A. Choose **Custom pattern (JSON editor)**.
 - B. In the **Event pattern** box, add the event pattern for this example.
- c. Choose **Next**.
5. For **Select target(s)**, do the following:
 - a. For **Target types**, choose **AWS service**.
 - b. For **Select a target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.
 - c. For **Topic**, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see [Using Amazon SNS for application-to-person \(A2P\) messaging](#) in the *Amazon Simple Notification Service Developer Guide*.
 - d. (Optional) Under **Additional settings**, you can optionally configure additional settings. For more information, see [Creating Amazon EventBridge rules that react to events](#) (step 16) in the *Amazon EventBridge User Guide*.
 - e. Choose **Next**.
6. (Optional) For **Tags**, you can optionally assign one or more tags to your rule, and then choose **Next**.
7. For **Review and create**, do the following:
 - a. Review the details of the rule and modify them as necessary.
 - b. Choose **Create rule**.

For more information, see [Amazon EventBridge rules](#) and [Amazon EventBridge event patterns](#) in the *Amazon EventBridge User Guide*

Use instance metadata

The instance metadata category events/recommendations/rebalance provides the approximate time, in UTC, when the rebalance recommendation signal was emitted for a Spot Instance.

We recommend that you check for rebalance recommendation signals every 5 seconds so that you don't miss an opportunity to act on the rebalance recommendation.

If a Spot Instance receives a rebalance recommendation, the time that the signal was emitted is present in the instance metadata. You can retrieve the time that the signal was emitted as follows.

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/events/recommendations/rebalance
```

The following is example output, which indicates the time, in UTC, that the rebalance recommendation signal was emitted for the Spot Instance.

```
{"noticeTime": "2020-10-27T08:22:00Z"}
```

If the signal has not been emitted for the instance, events/recommendations/rebalance is not present and you receive an HTTP 404 error when you try to retrieve it.

Services that use the rebalance recommendation signal

Amazon EC2 Auto Scaling, EC2 Fleet, and Spot Fleet use the rebalance recommendation signal to make it easy for you to maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running instance receives the two-minute Spot Instance interruption notice. You can have these services monitor and respond proactively to changes affecting the availability of your Spot Instances. For more information, see the following:

- [Use Capacity Rebalancing to handle Amazon EC2 Spot interruptions](#) in the *Amazon EC2 Auto Scaling User Guide*
- [Capacity Rebalancing \(p. 1001\)](#) in the EC2 Fleet topic in this user guide
- [Capacity Rebalancing \(p. 1044\)](#) in the Spot Fleet topic in this user guide

Spot Instance interruptions

You can launch Spot Instances on spare EC2 capacity for steep discounts in exchange for returning them when Amazon EC2 needs the capacity back. When Amazon EC2 reclaims a Spot Instance, we call this event a *Spot Instance interruption*.

When Amazon EC2 interrupts a Spot Instance, it either terminates, stops, or hibernates the instance, depending on what you specified when you created the Spot request.

Demand for Spot Instances can vary significantly from moment to moment, and the availability of Spot Instances can also vary significantly depending on how many unused EC2 instances are available. It is always possible that your Spot Instance might be interrupted.

An On-Demand Instance specified in an EC2 Fleet or Spot Fleet cannot be interrupted.

Contents

- [Reasons for interruption \(p. 433\)](#)
- [Interruption behavior \(p. 434\)](#)
- [Stop interrupted Spot Instances \(p. 434\)](#)
- [Hibernate interrupted Spot Instances \(p. 435\)](#)
- [Terminate interrupted Spot Instances \(p. 438\)](#)
- [Prepare for interruptions \(p. 438\)](#)
- [Initiate a Spot Instance interruption \(p. 438\)](#)
- [Spot Instance interruption notices \(p. 440\)](#)
- [Find interrupted Spot Instances \(p. 441\)](#)
- [Determine whether Amazon EC2 terminated a Spot Instance \(p. 442\)](#)
- [Billing for interrupted Spot Instances \(p. 443\)](#)

Reasons for interruption

The following are the possible reasons that Amazon EC2 might interrupt your Spot Instances:

Capacity

Amazon EC2 can interrupt your Spot Instance when it needs it back. EC2 reclaims your instance mainly to repurpose capacity, but it can also occur for other reasons such as host maintenance or hardware decommission.

Price

The Spot price is higher than your maximum price.

You can specify the maximum price in your Spot request. However, if you specify a maximum price, your instances will be interrupted more frequently than if you do not specify it.

Constraints

If your Spot request includes a constraint such as a launch group or an Availability Zone group, the Spot Instances are terminated as a group when the constraint can no longer be met.

You can see the historical interruption rates for your instance type in the [Spot Instance Advisor](#).

Interruption behavior

You can specify that Amazon EC2 must do one of the following when it interrupts a Spot Instance:

- [Stop interrupted Spot Instances \(p. 434\)](#)
- [Hibernate interrupted Spot Instances \(p. 435\)](#)
- [Terminate interrupted Spot Instances \(p. 438\)](#) (this is the default behavior)

Specify the interruption behavior

You can specify the interruption behavior when you create a Spot request. If you do not specify an interruption behavior, the default is that Amazon EC2 terminates Spot Instances when they are interrupted.

The way in which you specify the interruption behavior is different depending on how you request Spot Instances.

- If you request Spot Instances using the [launch instance wizard \(p. 552\)](#), you can specify the interruption behavior as follows: From **Request type**, choose **Persistent** (new console) or select the **Persistent request** check box (old console) and then, from **Interruption behavior**, choose an interruption behavior.
- If you request Spot Instances using the [Spot console \(p. 1058\)](#), you can specify the interruption behavior as follows: Select the **Maintain target capacity** check box and then, from **Interruption behavior**, choose an interruption behavior.
- If you configure Spot Instances in a [launch template \(p. 570\)](#), you can specify the interruption behavior as follows: In the launch template, expand **Advanced details** and select the **Request Spot Instances** check box. Choose **Customize** and then, from **Interruption behavior**, choose an interruption behavior.
- If you configure Spot Instances in the request configuration when using the [create-fleet](#) CLI, you can specify the interruption behavior as follows: For **InstanceInterruptionBehavior**, specify an interruption behavior.
- If you configure Spot Instances in the request configuration when using the [request-spot-fleet](#) CLI, you can specify the interruption behavior as follows: For **InstanceInterruptionBehavior**, specify an interruption behavior.
- If you configure Spot Instances using the [request-spot-instances](#) CLI, you can specify the interruption behavior as follows: For **--instance-interruption-behavior**, specify an interruption behavior.

Stop interrupted Spot Instances

You can specify that Amazon EC2 stops your Spot Instances when they are interrupted. For more information, see [Specify the interruption behavior \(p. 434\)](#).

Considerations

- Only Amazon EC2 can restart an interrupted stopped Spot Instance.
- For a Spot Instance launched by a persistent Spot Instance request: Amazon EC2 restarts the stopped instance when capacity is available in the same Availability Zone and for the same instance type as the stopped instance (the same launch specification must be used).
- For Spot Instances launched by an EC2 Fleet or Spot Fleet of type **maintain**: After a Spot Instance is interrupted, Amazon EC2 launches a replacement instance to maintain the target capacity. Amazon EC2 finds the best Spot capacity pools based on the specified allocation strategy (**lowestPrice**, **diversified**, or **InstancePoolsToUseCount**); it does not prioritize the pool with the earlier

stopped instance. Later, if the allocation strategy leads to a pool containing the earlier stopped instance, Amazon EC2 restarts the stopped instance to meet the target capacity.

For example, consider a Spot Fleet with the `lowestPrice` allocation strategy. At initial launch, a `c3.large` pool meets the `lowestPrice` criteria for the launch specification. Later, when the `c3.large` instances are interrupted, Amazon EC2 stops the instances and replenishes capacity from another pool that fits the `lowestPrice` strategy. This time, the pool happens to be a `c4.large` pool and Amazon EC2 launches `c4.large` instances to meet the target capacity. Similarly, Spot Fleet could move to a `c5.large` pool the next time. In each of these transitions, Amazon EC2 does not prioritize pools with earlier stopped instances, but rather prioritizes purely on the specified allocation strategy. The `lowestPrice` strategy can lead back to pools with earlier stopped instances. For example, if instances are interrupted in the `c5.large` pool and the `lowestPrice` strategy leads it back to the `c3.large` or `c4.large` pools, the earlier stopped instances are restarted to fulfill target capacity.

- While a Spot Instance is stopped, you can modify some of its instance attributes, but not the instance type. If you detach or delete an EBS volume, it is not attached when the Spot Instance is started. If you detach the root volume and Amazon EC2 attempts to start the Spot Instance, the instance will fail to start and Amazon EC2 will terminate the stopped instance.
- You can terminate a Spot Instance while it is stopped.
- If you cancel a Spot Instance request, an EC2 Fleet, or a Spot Fleet, Amazon EC2 terminates any associated Spot Instances that are stopped.
- While an interrupted Spot Instance is stopped, you are charged only for the EBS volumes, which are preserved. With EC2 Fleet and Spot Fleet, if you have many stopped instances, you can exceed the limit on the number of EBS volumes for your account. For more information about how you're charged when a Spot Instance is interrupted, see [Billing for interrupted Spot Instances \(p. 443\)](#).
- Make sure that you are familiar with the implications of stopping an instance. For information about what happens when an instance is stopped, see [Differences between reboot, stop, hibernate, and terminate \(p. 549\)](#).

Prerequisites

To stop an interrupted Spot Instance, the following prerequisites must be in place:

Spot request type

Spot Instance request type – Must be persistent. You can't specify a launch group in the Spot Instance request.

EC2 Fleet or Spot Fleet request type – Must be maintain.

Root volume type

Must be an EBS volume, not an instance store volume.

Hibernate interrupted Spot Instances

You can specify that Amazon EC2 hibernates your Spot Instances when they are interrupted. For more information, see [Specify the interruption behavior \(p. 434\)](#).

When Amazon EC2 hibernates a Spot Instance, the following occurs:

- When the instance receives a signal from Amazon EC2, the agent prompts the operating system to hibernate. If the agent is not installed, or the underlying operating system doesn't support hibernation, or there isn't enough volume space to save the instance memory, hibernation fails and Amazon EC2 stops the instance instead.
- The instance memory (RAM) is preserved on the root volume.
- The EBS volumes and private IP addresses of the instance are preserved.

- Instance store volumes and public IP addresses, other than Elastic IP addresses, are not preserved.

For information about hibernating On-Demand Instances, see [Hibernate your On-Demand Windows instance \(p. 602\)](#).

Considerations

- Only Amazon EC2 can hibernate a Spot Instance. You can't manually hibernate a Spot Instance.
- Only Amazon EC2 can resume a hibernated Spot Instance. You can't manually resume a hibernated Spot Instance.
- Amazon EC2 resumes the instance when capacity becomes available.
- When Amazon EC2 hibernates a Spot Instance, hibernation begins immediately. You receive an interruption notice, but you do not have two minutes before the Spot Instance is interrupted.
- While the instance is in the process of hibernating, instance health checks might fail.
- When the hibernation process completes, the state of the instance is stopped.
- While the instance is hibernated, you are charged only for the EBS volumes. With EC2 Fleet and Spot Fleet, if you have many hibernated instances, you can exceed the limit on the number of EBS volumes for your account.
- Make sure that you are familiar with the implications of hibernating an instance. For information about what happens when an instance is hibernated, see [Differences between reboot, stop, hibernate, and terminate \(p. 549\)](#).

Prerequisites

To hibernate a Spot Instance, the following prerequisites must be in place:

Spot request type

Spot Instance request type – Must be persistent. You can't specify a launch group in the Spot Instance request.

EC2 Fleet or Spot Fleet request type – Must be maintain.

Supported Windows AMIs

The following supported AMIs include the hibernation agent. To use an earlier version of the following AMIs, you must [install the hibernation agent \(p. 437\)](#).

- Windows Server 2008 R2 AMI 2017.11.19 or later
- Windows Server 2012 or Windows Server 2012 R2 AMI 2017.11.19 or later
- Windows Server 2016 AMI 2017.11.19 or later
- Windows Server 2019

¹ To use an earlier version of the Ubuntu Xenial AMI, it must have a Ubuntu kernel tuned by AWS(linux-aws) greater than 4.4.0-1041.

For information about the supported Linux AMIs, see the [prerequisites](#) in the *Amazon EC2 User Guide for Linux Instances*.

Start the hibernation agent

We recommend that you use user data to start the hibernation agent at instance launch. Alternatively, you could start the agent manually. For more information, see [Start the hibernation agent at launch \(p. 437\)](#).

Supported instance families

C3, C4, C5, M4, M5, R3, R4

Instance RAM size

Can be up to 16 GB.

Root volume type

Must be an EBS volume, not an instance store volume.

EBS root volume size

Must be large enough to store the instance memory (RAM) during hibernation.

EBS root volume encryption – recommended, but not a prerequisite for Spot Instance hibernation

We strongly recommend that you use an encrypted EBS volume as the root volume, because instance memory is stored on the root volume during hibernation. This ensures that the contents of memory (RAM) are encrypted when the data is at rest on the volume and when data is moving between the instance and volume.

Use one of the following three options to ensure that the root volume is an encrypted EBS volume:

- **EBS encryption by default** – You can enable EBS encryption by default to ensure that all new EBS volumes created in your AWS account are encrypted. This way, you can enable hibernation for your instances without specifying encryption intent at instance launch. For more information, see [Encryption by default \(p. 1925\)](#).
- **EBS "single-step" encryption** – You can launch encrypted EBS-backed EC2 instances from an unencrypted AMI and also enable hibernation at the same time. For more information, see [Use encryption with EBS-backed AMIs \(p. 193\)](#).
- **Encrypted AMI** – You can enable EBS encryption by using an encrypted AMI to launch your instance. If your AMI does not have an encrypted root snapshot, you can copy it to a new AMI and request encryption. For more information, see [Encrypt an unencrypted image during copy \(p. 196\)](#) and [Copy an AMI \(p. 168\)](#).

Install the hibernation agent on your Windows AMI

You must install the hibernation agent on your AMI, unless you plan to use an AMI that already includes the agent.

The following instructions describe how to install the hibernation agent on a Windows AMI. For the instructions to install the hibernation agent on a Linux AMI, see [Install the hibernation agent on your on Linux AMI](#) in the *Amazon EC2 User Guide for Linux Instances*.

To install the hibernation agent on a Windows AMI

If your AMI doesn't include the agent, download the following files to the C:\Program Files\Amazon\Hibernate folder on your Windows instance.

- [EC2HibernateAgent.exe](#)
- [EC2HibernateAgent.ps1](#)
- [LICENSE.txt](#)

Start the hibernation agent at launch

The hibernation agent must run at instance startup, whether the agent was included in your AMI or you installed it yourself.

The following instructions describe how to start the hibernation agent on a Windows instance. For the instructions to start the hibernation agent on a Linux instance, see [Start the hibernation agent at launch](#) in the *Amazon EC2 User Guide for Linux Instances*.

To start the hibernation agent on a Spot Instance

Follow the steps to request a Spot Instance using your preferred [launch method \(p. 551\)](#), and add the following to the user data.

```
<powershell>."C:\Program Files\Amazon\Hibernate\EC2HibernateAgent.exe"</powershell>
```

Terminate interrupted Spot Instances

When Amazon EC2 interrupts a Spot Instance, it terminates the instance by default, unless you specify a different interruption behavior, such as stop or hibernate. For more information, see [Specify the interruption behavior \(p. 434\)](#).

Prepare for interruptions

Demand for Spot Instances can vary significantly from moment to moment, and the availability of Spot Instances can also vary significantly depending on how many unused EC2 instances are available. It is always possible that your Spot Instance might be interrupted. Therefore, you must ensure that your application is prepared for a Spot Instance interruption.

We recommend that you follow these best practices so that you're prepared for a Spot Instance interruption.

- Create your Spot request using an Auto Scaling group. If your Spot Instances are interrupted, the Auto Scaling group will automatically launch replacement instances. For more information, see [Auto Scaling groups with multiple instance types and purchase options](#) in the *Amazon EC2 Auto Scaling User Guide*.
- Ensure that your instance is ready to go as soon as the request is fulfilled by using an Amazon Machine Image (AMI) that contains the required software configuration. You can also use user data to run commands at startup.
- Data on instance store volumes is lost when the instance is stopped or terminated. Back up any important data on instance store volumes to a more persistent storage, such as Amazon S3, Amazon EBS, or Amazon DynamoDB.
- Store important data regularly in a place that isn't affected if the Spot Instance terminates. For example, you can use Amazon S3, Amazon EBS, or DynamoDB.
- Divide the work into small tasks (using a Grid, Hadoop, or queue-based architecture) or use checkpoints so that you can save your work frequently.
- Amazon EC2 emits a rebalance recommendation signal to the Spot Instance when the instance is at an elevated risk of interruption. You can rely on the rebalance recommendation to proactively manage Spot Instance interruptions without having to wait for the two-minute Spot Instance interruption notice. For more information, see [EC2 instance rebalance recommendations \(p. 429\)](#).
- Use the two-minute Spot Instance interruption notices to monitor the status of your Spot Instances. For more information, see [Spot Instance interruption notices \(p. 440\)](#).
- While we make every effort to provide these warnings as soon as possible, it is possible that your Spot Instance is interrupted before the warnings can be made available. Test your application to ensure that it handles an unexpected instance interruption gracefully, even if you are monitoring for rebalance recommendation signals and interruption notices. You can do this by running the application using an On-Demand Instance and then terminating the On-Demand Instance yourself.
- Run a controlled fault injection experiment with AWS Fault Injection Simulator to test how your application responds when your Spot Instance is interrupted. For more information, see the [Tutorial: Test Spot Instance interruptions using AWS FIS](#) in the *AWS Fault Injection Simulator User Guide*.

Initiate a Spot Instance interruption

You can select a Spot Instance in the Amazon EC2 console and initiate an interruption so that you can test how the applications on your Spot Instances handle being interrupted. When you initiate a

Spot Instance interruption, Amazon EC2 notifies you that your Spot Instance will be interrupted in two minutes, and then, after two minutes, Amazon EC2 interrupts the Spot Instance.

The underlying service that performs the Spot Instance interruption is AWS Fault Injection Simulator (AWS FIS). For information about AWS FIS, see [AWS Fault Injection Simulator](#).

Note

Interruption behaviors are terminate, stop, and hibernate. If you set the interruption behavior to hibernate, when you initiate a Spot Instance interruption, the hibernation process will begin immediately.

Initiating a Spot Instance interruption is supported in all AWS Regions except Asia Pacific (Jakarta), Asia Pacific (Osaka), China (Beijing), China (Ningxia), and Middle East (UAE).

Topics

- [Initiate a Spot Instance interruption \(p. 439\)](#)
- [Verify the Spot Instance interruption \(p. 439\)](#)

Initiate a Spot Instance interruption

You can use the EC2 console to quickly initiate a Spot Instance interruption. For more advanced experiments to test Spot Instance interruptions, you can create your own experiments using the AWS FIS console.

To initiate a Spot Instance interruption using the EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation pane, choose **Spot Requests**.
3. Select a Spot Instance request, and then choose **Actions, Initiate interruption**.

Note

Selecting a Spot Fleet request to initiate interrupting all the Spot Instances in the fleet at once is currently not supported; you must select each Spot Instance request in the fleet separately. You also can't select multiple Spot Instance requests to initiate an interruption; you can only initiate an interruption for one Spot Instance at a time.

4. In the **Initiate Spot Instance interruption** dialog box, under **Service access**, either use the default role, or choose an existing role. To choose a role, choose **Use an existing service role**, and then, for **Service role name**, select the role to use.
5. When you're ready to initiate the Spot Instance interruption, choose **Initiate interruption**.

To create more advanced experiments to test Spot Instance interruptions using the AWS FIS console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation pane, choose **Spot Requests**.
3. Choose **Actions, Create advanced experiments**.

The AWS FIS console opens. For more information, see [Tutorial: Test Spot Instance interruptions using AWS FIS](#) in the *AWS Fault Injection Simulator User Guide*.

Verify the Spot Instance interruption

After you initiate the interruption, the following occurs:

- The Spot Instance receives an [instance rebalance recommendation \(p. 429\)](#).

- A [Spot Instance interruption notice \(p. 440\)](#) is issued two minutes before Amazon EC2 interrupts your instance.
- After two minutes, the Spot Instance is interrupted.
- A Spot Instance that was stopped by AWS FIS remains stopped until you restart it.

To verify that the instance was interrupted after you initiated the interruption

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation pane, open **Spot Requests** and **Instances** in separate browser tabs or windows.
3. For **Spot Requests**, select the Spot Instance request. The initial status is fulfilled. After the instance is interrupted, the status changes as follows, depending on the interruption behavior:
 - terminate – The status changes to instance-terminated-by-experiment.
 - stop – The status changes to marked-for-stop-by-experiment and then instance-stopped-by-experiment.
4. For **Instances**, select the Spot Instance. The initial status is Running. Two minutes after you receive the Spot Instance interruption notice, the status changes as follows, depending on the interruption behavior:
 - stop – The status changes to Stopping and then Stopped.
 - terminate – The status changes to Shutting-down and then Terminated.

Spot Instance interruption notices

A *Spot Instance interruption notice* is a warning that is issued two minutes before Amazon EC2 stops or terminates your Spot Instance. If you specify hibernation as the interruption behavior, you receive an interruption notice, but you do not receive a two-minute warning because the hibernation process begins immediately.

The best way for you to gracefully handle Spot Instance interruptions is to architect your application to be fault-tolerant. To accomplish this, you can take advantage of Spot Instance interruption notices. We recommend that you check for these interruption notices every 5 seconds.

The interruption notices are made available as a EventBridge event and as items in the [instance metadata \(p. 862\)](#) on the Spot Instance. Interruption notices are emitted on a best effort basis.

EC2 Spot Instance interruption notice

When Amazon EC2 is going to interrupt your Spot Instance, it emits an event two minutes prior to the actual interruption (except for hibernation, which gets the interruption notice, but not two minutes in advance, because hibernation begins immediately). This event can be detected by Amazon EventBridge. For more information about EventBridge events, see the [Amazon EventBridge User Guide](#). For a detailed example that walks you through how to create and use event rules, see [Taking Advantage of Amazon EC2 Spot Instance Interruption Notices](#).

The following is an example of the event for Spot Instance interruption. The possible values for instance-action are hibernate, stop, or terminate.

```
{  
    "version": "0",  
    "id": "12345678-1234-1234-1234-123456789012",  
    "detail-type": "EC2 Spot Instance Interruption Warning",  
    "source": "aws.ec2",  
    "account": "123456789012",  
    "time": "yyyy-mm-ddThh:mm:ssZ",  
    "region": "us-east-2",  
    "resources": ["arn:aws:ec2:us-east-2:123456789012:instance/i-1234567890abcdef0"]}
```

```
"detail": {  
    "instance-id": "i-1234567890abcdef0",  
    "instance-action": "action"  
}
```

instance-action

If your Spot Instance is marked to be stopped or terminated by Amazon EC2, the `instance-action` item is present in your [instance metadata \(p. 862\)](#). Otherwise, it is not present. You can retrieve `instance-action` as follows.

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/spot/instance-action
```

The `instance-action` item specifies the action and the approximate time, in UTC, when the action will occur.

The following example output indicates the time at which this instance will be stopped.

```
{"action": "stop", "time": "2017-09-18T08:22:00Z"}
```

The following example output indicates the time at which this instance will be terminated.

```
{"action": "terminate", "time": "2017-09-18T08:22:00Z"}
```

If Amazon EC2 is not preparing to stop or terminate the instance, or if you terminated the instance yourself, `instance-action` is not present in the instance metadata and you receive an HTTP 404 error when you try to retrieve it.

termination-time

This item is maintained for backward compatibility; you should use `instance-action` instead.

If your Spot Instance is marked for termination by Amazon EC2, the `termination-time` item is present in your instance metadata. Otherwise, it is not present. You can retrieve `termination-time` as follows.

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/spot/termination-time
```

The `termination-time` item specifies the approximate time in UTC when the instance receives the shutdown signal. The following is example output.

```
2015-01-05T18:02:00Z
```

If Amazon EC2 is not preparing to terminate the instance, or if you terminated the Spot Instance yourself, the `termination-time` item is either not present in the instance metadata (so you receive an HTTP 404 error) or contains a value that is not a time value.

If Amazon EC2 fails to terminate the instance, the request status is set to `fulfilled`. The `termination-time` value remains in the instance metadata with the original approximate time, which is now in the past.

Find interrupted Spot Instances

In the console, the **Instances** pane displays all instances, including Spot Instances. The instance lifecycle of a Spot Instance is spot. The instance state of a Spot Instance is either stopped or terminated,

depending on the interruption behavior that you configured. For a hibernated Spot Instance, the instance state is stopped.

To find an interrupted Spot Instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Apply the following filter: **Instance lifecycle=spot**.
4. Apply the **Instance state=stopped** or **Instance state=terminated** filter depending on the interruption behavior that you configured.
5. For each Spot Instance, on the **Details** tab, under **Instance details**, find **State transition message**. The following codes indicate that the Spot Instance was interrupted.
 - `Server.SpotInstanceShutdown`
 - `Server.SpotInstanceTermination`
6. For additional details about the reason for the interruption, check the Spot request status code. For more information, see [the section called "Spot request status" \(p. 423\)](#).

To find interrupted Spot Instances using the AWS CLI

You can list your interrupted Spot Instances using the [describe-instances](#) command with the `--filters` parameter. To list only the instance IDs in the output, include the `--query` parameter.

If the instance interruption behavior is to terminate the Spot Instances, use the following command:

```
aws ec2 describe-instances \
  --filters Name=instance-lifecycle,Values=spot Name=instance-state-
  name,Values=terminated Name=state-reason-code,Values=Server.SpotInstanceTermination \
  --query "Reservations[*].Instances[*].InstanceId"
```

If the instance interruption behavior is to stop the Spot Instances, use the following command:

```
aws ec2 describe-instances \
  --filters Name=instance-lifecycle,Values=spot Name=instance-state-name,Values=stopped
  Name=state-reason-code,Values=Server.SpotInstanceShutdown \
  --query "Reservations[*].Instances[*].InstanceId"
```

Determine whether Amazon EC2 terminated a Spot Instance

If a Spot Instance is terminated, you can use CloudTrail to see whether Amazon EC2 terminated the Spot Instance. In AWS CloudTrail, the event name `BidEvictedEvent` indicates that Amazon EC2 terminated the Spot Instance.

To view BidEvictedEvent events in CloudTrail

1. Open the CloudTrail console at <https://console.aws.amazon.com/cloudtrail/>.
2. In the navigation pane, choose **Event history**.
3. In the filter drop-down, choose **Event name**, and then in the filter field to the right, enter **BidEvictedEvent**.
4. Choose **BidEvictedEvent** in the resulting list to view its details. Under **Event record**, you can find the instance ID.

For more information about using CloudTrail, see [Log Amazon EC2 and Amazon EBS API calls with AWS CloudTrail \(p. 1216\)](#).

Billing for interrupted Spot Instances

When a Spot Instance is interrupted, you're charged for instance and EBS volume usage as follows.

Instance usage

Who interrupts the Spot Instance	Operating system	Interrupted in the first hour	Interrupted in any hour after the first hour
If you stop or terminate the Spot Instance	Windows and Linux (excluding RHEL and SUSE)	Charged for the seconds used	Charged for the seconds used
	RHEL and SUSE	Charged for the full hour even if you used a partial hour	Charged for the full hours used, and charged a full hour for the interrupted partial hour
If the Amazon EC2 interrupts the Spot Instance	Windows and Linux (excluding RHEL and SUSE)	No charge	Charged for the seconds used
	RHEL and SUSE	No charge	Charged for the full hours used, but no charge for the interrupted partial hour

EBS volume usage

While an interrupted Spot Instance is stopped, you are charged only for the EBS volumes, which are preserved.

With EC2 Fleet and Spot Fleet, if you have many stopped instances, you can exceed the limit on the number of EBS volumes for your account.

Spot placement score

The Spot placement score feature can recommend an AWS Region or Availability Zone based on your Spot capacity requirements. Spot capacity fluctuates, and you can't be sure that you'll always get the capacity that you need. A Spot placement score indicates how likely it is that a Spot request will succeed in a Region or Availability Zone.

Note

A Spot placement score does not provide any guarantees in terms of available capacity or risk of interruption. A Spot placement score serves only as a recommendation.

Benefits

You can use the Spot placement score feature for the following:

- To relocate and scale Spot compute capacity in a different Region, as needed, in response to increased capacity needs or decreased available capacity in the current Region.
- To identify the most optimal Availability Zone in which to run single-Availability Zone workloads.
- To simulate future Spot capacity needs so that you can pick an optimal Region for the expansion of your Spot-based workloads.
- To find an optimal combination of instance types to fulfill your Spot capacity needs.

Topics

- [Costs \(p. 444\)](#)
- [How Spot placement score works \(p. 444\)](#)
- [Limitations \(p. 446\)](#)
- [Required IAM permission \(p. 447\)](#)
- [Calculate a Spot placement score \(p. 447\)](#)
- [Example configurations \(p. 451\)](#)

Costs

There is no additional charge for using the Spot placement score feature.

How Spot placement score works

When you use the Spot placement score feature, you first specify your compute requirements for your Spot Instances, and then Amazon EC2 returns the top 10 Regions or Availability Zones where your Spot request is likely to succeed. Each Region or Availability Zone is scored on a scale from 1 to 10, with 10 indicating that your Spot request is highly likely to succeed, and 1 indicating that your Spot request is not likely to succeed.

To use the Spot placement score feature, follow these steps:

- [Step 1: Specify your Spot requirements \(p. 444\)](#)
- [Step 2: Filter the Spot placement score response \(p. 445\)](#)
- [Step 3: Review the recommendations \(p. 445\)](#)
- [Step 4: Use the recommendations \(p. 446\)](#)

Step 1: Specify your Spot requirements

First, you specify your desired target Spot capacity and your compute requirements, as follows:

1. **Specify the target Spot capacity, and optionally the target capacity unit.**

You can specify your desired target Spot capacity in terms of the number of instances or vCPUs, or in terms of the amount of memory in MiB. To specify the target capacity in number of vCPUs or amount of memory, you must specify the target capacity unit as `vcpu` or `memory-mib`. Otherwise, it defaults to number of instances.

By specifying your target capacity in terms of the number of vCPUs or the amount of memory, you can use these units when counting the total capacity. For example, if you want to use a mix of instances of different sizes, you can specify the target capacity as a total number of vCPUs. The Spot placement score feature then considers each instance type in the request by its number of vCPUs, and counts the total number of vCPUs rather than the total number of instances when totaling up the target capacity.

For example, say you specify a total target capacity of 30 vCPUs, and your instance type list consists of `c5.xlarge` (4 vCPUs), `m5.2xlarge` (8 vCPUs), and `r5.large` (2 vCPUs). To achieve a total of 30 vCPUs, you could get a mix of 2 `c5.xlarge` (2*4 vCPUs), 2 `m5.2xlarge` (2*8 vCPUs), and 3 `r5.large` (3*2 vCPUs).

2. Specify instance types or instance attributes.

You can either specify the instance types to use, or you can specify the instance attributes that you need for your compute requirements, and then let Amazon EC2 identify the instance types that have those attributes. This is known as attribute-based instance type selection.

You can't specify both instance types and instance attributes in the same Spot placement score request.

If you specify instance types, you must specify at least three different instance types, otherwise Amazon EC2 will return a low Spot placement score. Similarly, if you specify instance attributes, they must resolve to at least three different instance types.

For examples of different ways to specify your Spot requirements, see [Example configurations \(p. 451\)](#).

Step 2: Filter the Spot placement score response

Amazon EC2 calculates the Spot placement score for each Region or Availability Zone, and returns either the top 10 Regions or the top 10 Availability Zones where your Spot request is likely to succeed. The default is to return a list of scored Regions. If you plan to launch all of your Spot capacity into a single Availability Zone, then it's useful to request a list of scored Availability Zones.

You can specify a Region filter to narrow down the Regions that will be returned in the response.

You can combine the Region filter and a request for scored Availability Zones. In this way, the scored Availability Zones are confined to the Regions for which you've filtered. To find the highest-scored Availability Zone in a Region, specify only that Region, and the response will return a scored list of all of the Availability Zones in that Region.

Step 3: Review the recommendations

The Spot placement score for each Region or Availability Zone is calculated based on the target capacity, the composition of the instance types, the historical and current Spot usage trends, and the time of the request. Because Spot capacity is constantly fluctuating, the same Spot placement score request can yield different scores when calculated at different times.

Regions and Availability Zones are scored on a scale from 1 to 10. A score of 10 indicates that your Spot request is highly likely—but not guaranteed—to succeed. A score of 1 indicates that your Spot request is not likely to succeed at all. The same score might be returned for different Regions or Availability Zones.

If low scores are returned, you can edit your compute requirements and recalculate the score. You can also request Spot placement score recommendations for the same compute requirements at different times of the day.

Step 4: Use the recommendations

A Spot placement score is only relevant if your Spot request has exactly the same configuration as the Spot placement score configuration (target capacity, target capacity unit, and instance types or instance attributes), and is configured to use the capacity-optimized allocation strategy. Otherwise, the likelihood of getting available Spot capacity will not align with the score.

While a Spot placement score serves as a guideline, and no score guarantees that your Spot request will be fully or partially fulfilled, you can use the following information to get the best results:

- **Use the same configuration** – The Spot placement score is relevant only if the Spot request configuration (target capacity, target capacity unit, and instance types or instance attributes) in your Auto Scaling group, EC2 Fleet, or Spot Fleet is the same as what you entered to get the Spot placement score.

If you used attribute-based instance type selection in your Spot placement score request, you can use attribute-based instance type selection to configure your Auto Scaling group, EC2 Fleet, or Spot Fleet. For more information, see [Creating an Auto Scaling group with a set of requirements on the instance types used](#), [Attribute-based instance type selection for EC2 Fleet \(p. 986\)](#), and [Attribute-based instance type selection for Spot Fleet \(p. 1030\)](#).

Note

If you specified your target capacity in terms of the number of vCPUs or the amount of memory, and you specified instance types in your Spot placement score configuration, note that you can't currently create this configuration in your Auto Scaling group, EC2 Fleet, or Spot Fleet. Instead, you must manually set the instance weighting by using the `WeightedCapacity` parameter.

- **Use the capacity-optimized allocation strategy** – Any score assumes that your fleet request will be configured to use all Availability Zones (for requesting capacity across Regions) or a single Availability Zone (if requesting capacity in one Availability Zone) and the capacity-optimized Spot allocation strategy for your request for Spot capacity to succeed. If you use other allocation strategies, such as lowest-price, the likelihood of getting available Spot capacity will not align with the score.
- **Act on a score immediately** – The Spot placement score recommendation reflects the available Spot capacity at the time of the request, and the same configuration can yield different scores when calculated at different times due to Spot capacity fluctuations. While a score of 10 means that your Spot capacity request is highly likely—but not guaranteed—to succeed, for best results we recommend that you act on a score immediately. We also recommend that you get a fresh score each time you attempt a capacity request.

Limitations

- **Target capacity limit** – Your Spot placement score target capacity limit is based on your recent Spot usage, while accounting for potential usage growth. If you have no recent Spot usage, we provide you with a low default limit aligned with your Spot request limit.
- **Request configurations limit** – We can limit the number of new request configurations within a 24-hour period if we detect patterns not associated with the intended use of the Spot placement score feature. If you reach the limit, you can retry the request configurations that you've already used, but you can't specify new request configurations until the next 24-hour period.
- **Minimum number of instance types** – If you specify instance types, you must specify at least three different instance types, otherwise Amazon EC2 will return a low Spot placement score. Similarly, if you specify instance attributes, they must resolve to at least three different instance types. Instance types are considered different if they have a different name. For example, m5.8xlarge, m5a.8xlarge, and m5.12xlarge are all considered different.

Required IAM permission

By default, IAM identities (users, roles, or groups) don't have permission to use the Spot placement score feature. To allow IAM identities to use the Spot placement score feature, you must create an IAM policy that grants permission to use the `ec2:GetSpotPlacementScores` EC2 API action. You then attach the policy to the IAM identities that require this permission.

The following is an example IAM policy that grants permission to use the `ec2:GetSpotPlacementScores` EC2 API action.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "ec2:GetSpotPlacementScores",  
            "Resource": "*"  
        }  
    ]  
}
```

For information about editing an IAM policy, see [Editing IAM policies](#) in the *IAM User Guide*.

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center (successor to AWS Single Sign-On):
Create a permission set. Follow the instructions in [Create a permission set](#) in the *AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide*.
- Users managed in IAM through an identity provider:
Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider \(federation\)](#) in the *IAM User Guide*.
- IAM users:
 - Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the *IAM User Guide*.
 - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user \(console\)](#) in the *IAM User Guide*.

Calculate a Spot placement score

You can calculate a Spot placement score by using the Amazon EC2 console or the AWS CLI.

Topics

- [Calculate a Spot placement score by specifying instance attributes \(console\) \(p. 447\)](#)
- [Calculate a Spot placement score by specifying instance types \(console\) \(p. 448\)](#)
- [Calculate the Spot placement score \(AWS CLI\) \(p. 449\)](#)

Calculate a Spot placement score by specifying instance attributes (console)

To calculate a Spot placement score by specifying instance attributes

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests**.
3. Choose **Spot placement score**.

4. Choose **Enter requirements**.
5. For **Target capacity**, enter your desired capacity in terms of the number of **instances** or **vCPUs**, or the amount of **memory (MiB)**.
6. For **Instance type requirements**, to specify your compute requirements and let Amazon EC2 identify the optimal instance types with these requirements, choose **Specify instance attributes that match your compute requirements**.
7. For **vCPUs**, enter the desired minimum and maximum number of vCPUs. To specify no limit, select **No minimum, No maximum**, or both.
8. For **Memory (GiB)**, enter the desired minimum and maximum amount of memory. To specify no limit, select **No minimum, No maximum**, or both.
9. For **CPU architecture**, select the required instance architecture.
10. (Optional) For **Additional instance attributes**, you can optionally specify one or more attributes to express your compute requirements in more detail. Each additional attribute adds a further constraint to your request. You can omit the additional attributes; when omitted, the default values are used. For a description of each attribute and their default values, see [get-spot-placement-scores](#) in the *Amazon EC2 Command Line Reference*.
11. (Optional) To view the instance types with your specified attributes, expand **Preview matching instance types**. To exclude instance types from being used in the placement evaluation, select the instances and then choose **Exclude selected instance types**.
12. Choose **Load placement scores**, and review the results.
13. (Optional) To display the Spot placement score for specific Regions, for **Regions to evaluate**, select the Regions to evaluate, and then choose **Calculate placement scores**.
14. (Optional) To display the Spot placement score for the Availability Zones in the displayed Regions, select the **Provide placement scores per Availability Zone** check box. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone.
15. (Optional) To edit your compute requirements and get a new placement score, choose **Edit**, make the necessary adjustments, and then choose **Calculate placement scores**.

Calculate a Spot placement score by specifying instance types (console)

To calculate a Spot placement score by specifying instance types

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests**.
3. Choose **Spot placement score**.
4. Choose **Enter requirements**.
5. For **Target capacity**, enter your desired capacity in terms of the number of **instances** or **vCPUs**, or the amount of **memory (MiB)**.
6. For **Instance type requirements**, to specify the instance types to use, choose **Manually select instance types**.
7. Choose **Select instance types**, select the instance types to use, and then choose **Select**. To quickly find instance types, you can use the filter bar to filter the instance types by different properties.
8. Choose **Load placement scores**, and review the results.
9. (Optional) To display the Spot placement score for specific Regions, for **Regions to evaluate**, select the Regions to evaluate, and then choose **Calculate placement scores**.
10. (Optional) To display the Spot placement score for the Availability Zones in the displayed Regions, select the **Provide placement scores per Availability Zone** check box. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone.
11. (Optional) To edit the list of instance types and get a new placement score, choose **Edit**, make the necessary adjustments, and then choose **Calculate placement scores**.

Calculate the Spot placement score (AWS CLI)

To calculate the Spot placement score

1. (Optional) To generate all of the possible parameters that can be specified for the Spot placement score configuration, use the [get-spot-placement-scores](#) command and the --generate-cli-skeleton parameter.

```
aws ec2 get-spot-placement-scores \
--region us-east-1 \
--generate-cli-skeleton
```

Expected output

```
{
    "InstanceTypes": [

                            "DryRun": true,  
                            "MaxResults": 0,  
                            "NextToken": ""  
                        }  
                    }  
                }  
            }  
        }  
    }  
}
```

2. Create a JSON configuration file using the output from the previous step, and configure it as follows:

- For TargetCapacity, enter your desired Spot capacity in terms of the number of instances or vCPUs, or the amount of memory (MiB).
- For TargetCapacityUnitType, enter the unit for the target capacity. If you omit this parameter, it defaults to units.

Valid values: units (which translates to number of instances) | vcpu | memory-mib

- For SingleAvailabilityZone, specify true for a response that returns a list of scored Availability Zones. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone. If you omit this parameter, it defaults to false, and the response returns a list of scored Regions.
- (Optional) For RegionNames, specify the Regions to use as a filter. You must specify the Region code, for example, us-east-1.

With a Region filter, the response returns only the Regions that you specify. If you specified true for SingleAvailabilityZone, the response returns only the Availability Zones in the specified Regions.

- You can include either InstanceTypes or InstanceRequirements, but not both in the same configuration.

Specify one of the following in your JSON configuration:

- To specify a list of instance types, specify the instance types in the InstanceTypes parameter. Specify at least three different instance types. If you specify only one or two

instance types, Spot placement score returns a low score. For the list of instance types, see [Amazon EC2 Instance Types](#).

- To specify the instance attributes so that Amazon EC2 will identify the instance types that match those attributes, specify the attributes that are located in the `InstanceRequirements` structure.

You must provide values for `VCpuCount`, `MemoryMiB`, and `CpuManufacturers`. You can omit the other attributes; when omitted, the default values are used. For a description of each attribute and their default values, see [get-spot-placement-scores](#) in the *Amazon EC2 Command Line Reference*.

For example configurations, see [Example configurations \(p. 451\)](#).

- To get the Spot placement score for the requirements that you specified in the JSON file, use the [get-spot-placement-scores](#) command, and specify the name and path to your JSON file by using the `--cli-input-json` parameter.

```
aws ec2 get-spot-placement-scores \
--region us-east-1 \
--cli-input-json file://file_name.json
```

Example output if `SingleAvailabilityZone` is set to `false` or omitted (if omitted, it defaults to `false`) – a scored list of Regions is returned

```
"SpotPlacementScores": [
  {
    "Region": "us-east-1",
    "Score": 7
  },
  {
    "Region": "us-west-1",
    "Score": 5
  },
  ...
]
```

Example output if `SingleAvailabilityZone` is set to `true` – a scored list of Availability Zones is returned

```
"SpotPlacementScores": [
  {
    "Region": "us-east-1",
    "AvailabilityZoneId": "use1-az1",
    "Score": 8
  },
  {
    "Region": "us-east-1",
    "AvailabilityZoneId": "usw2-az3",
    "Score": 6
  },
  ...
]
```

Example configurations

When using the AWS CLI, you can use the following example configurations.

Example configurations

- [Example: Specify instance types and target capacity \(p. 452\)](#)

- [Example: Specify instance types, and target capacity in terms of memory \(p. 452\)](#)
- [Example: Specify attributes for attribute-based instance type selection \(p. 452\)](#)
- [Example: Specify attributes for attribute-based instance type selection and return a scored list of Availability Zones \(p. 453\)](#)

Example: Specify instance types and target capacity

The following example configuration specifies three different instance types and a target Spot capacity of 500 Spot Instances.

```
{  
    "InstanceTypes": [  
        "m5.4xlarge",  
        "r5.2xlarge",  
        "m4.4xlarge"  
    ],  
    "TargetCapacity": 500  
}
```

Example: Specify instance types, and target capacity in terms of memory

The following example configuration specifies three different instance types and a target Spot capacity of 500,000 MiB of memory, where the number of Spot Instances to launch must provide a total of 500,000 MiB of memory.

```
{  
    "InstanceTypes": [  
        "m5.4xlarge",  
        "r5.2xlarge",  
        "m4.4xlarge"  
    ],  
    "TargetCapacity": 500000,  
    "TargetCapacityUnitType": "memory-mib"  
}
```

Example: Specify attributes for attribute-based instance type selection

The following example configuration is configured for attribute-based instance type selection, and is followed by a text explanation of the example configuration.

```
{  
    "TargetCapacity": 5000,  
    "TargetCapacityUnitType": "vcpu",  
    "InstanceRequirementsWithMetadata": {  
        "ArchitectureTypes": ["arm64"],  
        "VirtualizationTypes": ["hvm"],  
        "InstanceRequirements": {  
            "VCpuCount": {  
                "Min": 1,  
                "Max": 12  
            },  
            "MemoryMiB": {  
                "Min": 512  
            }  
        }  
    }  
}
```

InstanceRequirementsWithMetadata

To use attribute-based instance type selection, you must include the `InstanceRequirementsWithMetadata` structure in your configuration, and specify the desired attributes for the Spot Instances.

In the preceding example, the following required instance attributes are specified:

- `ArchitectureTypes` – The architecture type of the instance types must be `arm64`.
- `VirtualizationTypes` – The virtualization type of the instance types must be `hvm`.
- `VCpuCount` – The instance types must have a minimum of 1 and a maximum of 12 vCPUs.
- `MemoryMiB` – The instance types must have a minimum of 512 MiB of memory. By omitting the `Max` parameter, you are indicating that there is no maximum limit.

Note that there are several other optional attributes that you can specify. For the list of attributes, see [get-spot-placement-scores](#) in the *Amazon EC2 Command Line Reference*.

TargetCapacityUnitType

The `TargetCapacityUnitType` parameter specifies the unit for the target capacity. In the example, the target capacity is 5000 and the target capacity unit type is `vcpu`, which together specify a desired target capacity of 5000 vCPUs, where the number of Spot Instances to launch must provide a total of 5000 vCPUs.

Example: Specify attributes for attribute-based instance type selection and return a scored list of Availability Zones

The following example configuration is configured for attribute-based instance type selection. By specifying "SingleAvailabilityZone": true, the response will return a list of scored Availability Zones.

```
{  
    "TargetCapacity": 1000,  
    "TargetCapacityUnitType": "vcpu",  
    "SingleAvailabilityZone": true,  
    "InstanceRequirementsWithMetadata": {  
        "ArchitectureTypes": ["arm64"],  
        "VirtualizationTypes": ["hvm"],  
        "InstanceRequirements": {  
            "VCpuCount": {  
                "Min": 1,  
                "Max": 12  
            },  
            "MemoryMiB": {  
                "Min": 512  
            }  
        }  
    }  
}
```

Spot Instance data feed

To help you understand the charges for your Spot Instances, Amazon EC2 provides a data feed that describes your Spot Instance usage and pricing. This data feed is sent to an Amazon S3 bucket that you specify when you subscribe to the data feed.

Data feed files arrive in your bucket typically once an hour, and each hour of usage is typically covered in a single data file. These files are compressed (gzip) before they are delivered to your bucket. Amazon EC2

can write multiple files for a given hour of usage where files are large (for example, when file contents for the hour exceed 50 MB before compression).

Note

You can create only one Spot Instance data feed per AWS account. If you don't have a Spot Instance running during a certain hour, you don't receive a data feed file for that hour.

Spot Instance data feed is supported in all AWS Regions except China (Beijing), China (Ningxia), AWS GovCloud (US), and the [Regions that are disabled by default](#).

Contents

- [Data feed file name and format \(p. 454\)](#)
- [Amazon S3 bucket requirements \(p. 455\)](#)
- [Subscribe to your Spot Instance data feed \(p. 455\)](#)
- [Describe your Spot Instance data feed \(p. 456\)](#)
- [Delete your Spot Instance data feed \(p. 456\)](#)

Data feed file name and format

The Spot Instance data feed file name uses the following format (with the date and hour in UTC):

`bucket-name.s3.amazonaws.com/optional-prefix/aws-account-id.YYYY-MM-DD-HH.n.unique-id.gz`

For example, if your bucket name is **my-bucket-name** and your prefix is **my-prefix**, your file names are similar to the following:

`my-bucket-name.s3.amazonaws.com/my-prefix/111122223333.2019-03-17-20.001.pwBdGTJG.gz`

For more information about bucket names, see [Rules for bucket naming](#) in the *Amazon Simple Storage Service User Guide*.

The Spot Instance data feed files are tab-delimited. Each line in the data file corresponds to one instance hour and contains the fields listed in the following table.

Field	Description
Timestamp	The timestamp used to determine the price charged for this instance usage.
UsageType	The type of usage and instance type being charged for. For m1.small Spot Instances, this field is set to SpotUsage. For all other instance types, this field is set to SpotUsage:{instance-type}. For example, SpotUsage:c1.medium.
Operation	The product being charged for. For Linux Spot Instances, this field is set to RunInstances. For Windows Spot Instances, this field is set to RunInstances:0002. Spot usage is grouped according to Availability Zone.
InstanceID	The ID of the Spot Instance that generated this instance usage.
MyBidID	The ID for the Spot Instance request that generated this instance usage.
MyMaxPrice	The maximum price specified for this Spot request.
MarketPrice	The Spot price at the time specified in the Timestamp field.

Field	Description
Charge	The price charged for this instance usage.
Version	The version included in the data feed file name for this record.

Amazon S3 bucket requirements

When you subscribe to the data feed, you must specify an Amazon S3 bucket to store the data feed files.

Before you choose an Amazon S3 bucket for the data feed, consider the following:

- You must have FULL_CONTROL permission to the bucket, which includes permission for the s3:GetBucketAcl and s3:PutBucketAcl actions.

If you're the bucket owner, you have this permission by default. Otherwise, the bucket owner must grant your AWS account this permission.

- When you subscribe to a data feed, these permissions are used to update the bucket ACL to give the AWS data feed account FULL_CONTROL permission. The AWS data feed account writes data feed files to the bucket. If your account doesn't have the required permissions, the data feed files cannot be written to the bucket. For more information, see [Logs sent to Amazon S3](#) in the *Amazon CloudWatch Logs User Guide*.

Note

If you update the ACL and remove the permissions for the AWS data feed account, the data feed files cannot be written to the bucket. You must resubscribe to the data feed to receive the data feed files.

- Each data feed file has its own ACL (separate from the ACL for the bucket). The bucket owner has FULL_CONTROL permission to the data files. The AWS data feed account has read and write permissions.
- If you delete your data feed subscription, Amazon EC2 doesn't remove the read and write permissions for the AWS data feed account on either the bucket or the data files. You must remove these permissions yourself.
- You must use a customer managed key if you encrypt your Amazon S3 bucket using server-side encryption with a AWS KMS key stored in AWS Key Management Service (SSE-KMS). For more information, see [Amazon S3 bucket server-side encryption](#) in the *Amazon CloudWatch Logs User Guide*.

Note

For Spot Instance data feed, the resource that generates the S3 files is no longer Amazon CloudWatch Logs. Therefore, you must remove the aws:SourceArn section from the S3 bucket permission policy and from the KMS policy.

Subscribe to your Spot Instance data feed

To subscribe to your data feed, use the [create-spot-datafeed-subscription](#) command.

```
aws ec2 create-spot-datafeed-subscription \
--bucket my-bucket-name \
[--prefix my-prefix]
```

Example output

```
{  
    "SpotDatafeedSubscription": {
```

```
        "OwnerId": "111122223333",
        "Bucket": "my-bucket-name",
        "Prefix": "my-prefix",
        "State": "Active"
    }
}
```

Describe your Spot Instance data feed

To describe your data feed subscription, use the [describe-spot-datafeed-subscription](#) command.

```
aws ec2 describe-spot-datafeed-subscription
```

Example output

```
{
    "SpotDatafeedSubscription": {
        "OwnerId": "123456789012",
        "Prefix": "spotdata",
        "Bucket": "my-s3-bucket",
        "State": "Active"
    }
}
```

Delete your Spot Instance data feed

To delete your data feed, use the [delete-spot-datafeed-subscription](#) command.

```
aws ec2 delete-spot-datafeed-subscription
```

Spot Instance quotas

There are quotas for the number of running Spot Instances and pending Spot Instance requests per AWS account per Region. Once a pending Spot Instance request is fulfilled, the request no longer counts towards the quota because the running instance is counted towards the quota.

Spot Instance quotas are managed in terms of the *number of virtual central processing units (vCPUs)* that your running Spot Instances are either using or will use pending the fulfillment of open Spot Instance requests. If you terminate your Spot Instances but do not cancel the Spot Instance requests, the requests count against your Spot Instance vCPU quota until Amazon EC2 detects the Spot Instance terminations and closes the requests.

We provide the following quota types for Spot Instances:

- All DL Spot Instance Requests
- All F Spot Instance Requests
- All G and VT Spot Instance Requests
- All Inf Spot Instance Requests
- All P Spot Instance Requests
- All Standard (A, C, D, H, I, M, R, T, Z) Spot Instance Requests
- All Trn Spot Instance Requests
- All X Spot Instance Requests

Each quota type specifies the maximum number of vCPUs for one or more instance families. For information about the different instance families, generations, and sizes, see [Amazon EC2 Instance Types](#).

You can launch any combination of instance types that meet your changing application needs. For example, with an All Standard Spot Instance Requests quota of 256 vCPUs, you could request 32 m5.2xlarge Spot Instances (32 x 8 vCPUs) or 16 c5.4xlarge Spot Instances (16 x 16 vCPUs).

Tasks

- [Monitor Spot Instance quotas and usage \(p. 457\)](#)
- [Request a quota increase \(p. 457\)](#)

Monitor Spot Instance quotas and usage

You can view and manage your Spot Instance quotas using the following:

- The Amazon EC2 [Services quotas page](#) in the Service Quotas console
- The [get-service-quota](#) AWS CLI

For more information, see [Amazon EC2 service quotas \(p. 2100\)](#) in the *Amazon EC2 User Guide for Linux Instances* and [Viewing service quotas](#) in the *Service Quotas User Guide*.

With Amazon CloudWatch metrics integration, you can monitor EC2 usage against your quotas. You can also configure alarms to warn about approaching quotas. For more information, see [Service Quotas and Amazon CloudWatch alarms](#) in the *Service Quotas User Guide*.

Request a quota increase

Even though Amazon EC2 automatically increases your Spot Instance quotas based on your usage, you can request a quota increase if necessary. For example, if you intend to launch more Spot Instances than your current quota allows, you can request a quota increase. You can also request a quota increase if you submit a Spot Instance request and you receive the error Max spot instance count exceeded. To request a quota increase, use the Service Quotas console described in [Amazon EC2 service quotas \(p. 2100\)](#).

Burstable performance instances

The T instance types are [burstable performance instances \(p. 245\)](#). If you launch your Spot Instances using a burstable performance instance type, and if you plan to use your burstable performance Spot Instances immediately and for a short duration, with no idle time for accruing CPU credits, we recommend that you launch them in [Standard mode \(p. 260\)](#) to avoid paying higher costs. If you launch burstable performance Spot Instances in [Unlimited mode \(p. 253\)](#) and burst CPU immediately, you'll spend surplus credits for bursting. If you use the instance for a short duration, the instance doesn't have time to accrue CPU credits to pay down the surplus credits, and you are charged for the surplus credits when you terminate the instance.

Unlimited mode is suitable for burstable performance Spot Instances only if the instance runs long enough to accrue CPU credits for bursting. Otherwise, paying for surplus credits makes burstable performance Spot Instances more expensive than using other instances. For more information, see [When to use unlimited mode versus fixed CPU \(p. 255\)](#).

T2 instances, when configured in [Standard mode \(p. 260\)](#), get [launch credits \(p. 261\)](#). T2 instances are the only burstable performance instances that get launch credits. Launch credits are meant to provide a productive initial launch experience for T2 instances by providing sufficient compute resources to configure the instance. Repeated launches of T2 instances to access new launch credits is not

permitted. If you require sustained CPU, you can earn credits (by idling over some period), use [Unlimited mode \(p. 253\)](#) for T2 Spot Instances, or use an instance type with dedicated CPU.

Dedicated Hosts

An Amazon EC2 Dedicated Host is a physical server with EC2 instance capacity fully dedicated to your use. Dedicated Hosts allow you to use your existing per-socket, per-core, or per-VM software licenses, including Windows Server, Microsoft SQL Server, SUSE, and Linux Enterprise Server.

Contents

Instance capacity configurations

Dedicated Hosts support different configurations (physical cores, sockets, and VCPUs) that allow you to run instances of different families and sizes.

When you allocate a Dedicated Host in your account, you can choose a configuration that supports either a **single instance type**, or **multiple instance types** within the same instance family. The number of instances that you can run on a host depends on the configuration you choose.

Contents

- [Single instance type support \(p. 458\)](#)
- [Multiple instance type support \(p. 459\)](#)

Single instance type support

You can allocate a Dedicated Host that supports only one instance type. With this configuration, every instance that you launch on the Dedicated Host must be of the same instance type, which you specify when you allocate the host.

For example, you can allocate a host that supports only the m5.4xlarge instance type. In this case, you can run only m5.4xlarge instances on that host.

The number of instances that you can launch onto the host depends on the number of physical cores provided by the host, and the number of cores consumed by the specified instance type. For example, if you allocate a host for m5.4xlarge instances, the host provides 48 physical cores, and each m5.4xlarge instance consumes 8 physical cores. This means that you can launch up to 6 instances on that host ($48 \text{ physical cores} / 8 \text{ cores per instance} = 6 \text{ instances}$).

Multiple instance type support

You can allocate a Dedicated Host that supports multiple instance types within the same instance family. This allows you to run different instance types on the same host, as long as they're in the same instance family and the host has sufficient instance capacity.

For example, you can allocate a host that supports different instance types within the R5 instance family. In this case, you can launch any combination of R5 instance types, such as `r5.large`, `r5.xlarge`, `r5.2xlarge`, and `r5.4xlarge`, on that host, up to the host's physical core capacity.

The following instance families support Dedicated Hosts with multiple instance type support:

- **General purpose:** A1, M5, M5n, M6i, and T3
- **Compute optimized:** C5, C5n, and C6i
- **Memory optimized:** R5, R5n, and R6i

The number of instances you can run on the host depends on the number of physical cores provided by the host, and the number of cores consumed by each instance type that you run on the host. For example, if you allocate an R5 host, which provides 48 physical cores, and you run two `r5.2xlarge` instances (*4 cores x 2 instances*) and three `r5.4xlarge` instances (*8 cores x 3 instances*), those instances consume a total of 32 cores, and you can run any combination of R5 instances as long as they do not exceed the remaining 16 cores.

However, for each instance family, there is a limit on the number of instances that can be run for each instance size. For example, an R5 Dedicated Host supports a maximum of 2 `r5.8xlarge` instances, which uses 32 of the physical cores. In this case, additional R5 instances of smaller sizes can then be used to fill the host to core capacity. For the supported number of instance sizes for each instance family, see the [Dedicated Hosts Configuration Table](#).

The following table shows example instance type combinations:

Instance family	Example instance size combinations
R5	<ul style="list-style-type: none">• Example 1: 4 x <code>r5.4xlarge</code> + 4 x <code>r5.2xlarge</code>• Example 2: 1 x <code>r5.12xlarge</code> + 1 x <code>r5.4xlarge</code> + 1 x <code>r5.2xlarge</code> + 5 x <code>r5.xlarge</code> + 2 x <code>r5.large</code>
C5	<ul style="list-style-type: none">• Example 1: 1 x <code>c5.9xlarge</code> + 2 x <code>c5.4xlarge</code> + 1 x <code>c5.xlarge</code>• Example 2: 4 x <code>c5.4xlarge</code> + 1 x <code>c5.xlarge</code> + 2 x <code>c5.large</code>
M5	<ul style="list-style-type: none">• Example 1: 4 x <code>m5.4xlarge</code> + 4 x <code>m5.2xlarge</code>• Example 2: 1 x <code>m5.12xlarge</code> + 1 x <code>m5.4xlarge</code> + 1 x <code>m5.2xlarge</code> + 5 x <code>m5.xlarge</code> + 2 x <code>m5.large</code>

Considerations

Keep the following in mind when working with Dedicated Hosts that support multiple instance types:

- With N-type Dedicated Hosts, such as C5n, M5n, and R5n, you can't mix smaller instance sizes (`2xlarge` and smaller) with larger instance sizes (`4xlarge` and larger, including `metal`). If you require smaller and larger instance sizes on N-type Dedicated Hosts at the same time, you must allocate separate hosts for the smaller and larger instance sizes.
- We recommend that you launch larger instance types first, and then fill the remaining instance capacity with smaller instance types as needed.

Differences between Dedicated Hosts and Dedicated Instances

Dedicated Instances and Dedicated Hosts can both be used to launch Amazon EC2 instances onto physical servers that are dedicated for your use.

There are no performance, security, or physical differences between Dedicated Instances and instances on Dedicated Hosts. However, there are some differences between the two. The following table highlights some of the key differences between Dedicated Instances and Dedicated Hosts:

	Dedicated Host	Dedicated Instance
Billing	Per-host billing	Per-instance billing
Visibility of sockets, cores, and host ID	Provides visibility of the number of sockets and physical cores	No visibility
Host and instance affinity	Allows you to consistently deploy your instances to the same physical server over time	Not supported
Targeted instance placement	Provides additional visibility and control over how instances are placed on a physical server	Not supported
Automatic instance recovery	Supported. For more information, see Host recovery (p. 488) .	Supported
Bring Your Own License (BYOL)	Supported	Partial support *
Capacity Reservations	Not supported	Supported

* Microsoft SQL Server with License Mobility through Software Assurance, and Windows Virtual Desktop Access (VDA) licenses can be used with Dedicated Instance.

For more information about Dedicated Instances, see [Dedicated Instances \(p. 499\)](#).

Bring your own license

Dedicated Hosts allow you to use your existing per-socket, per-core, or per-VM software licenses. When you bring your own license, you are responsible for managing your own licenses. However, Amazon EC2 has features that help you maintain license compliance, such as instance affinity and targeted placement.

These are the general steps to follow in order to bring your own volume licensed machine image into Amazon EC2.

1. Verify that the license terms controlling the use of your machine images allow usage in a virtualized cloud environment. For more information about Microsoft Licensing, see [Amazon Web Services and Microsoft Licensing](#).
2. After you have verified that your machine image can be used within Amazon EC2, import it using VM Import/Export. For information about how to import your machine image, see the [VM Import/Export User Guide](#).

3. After you import your machine image, you can launch instances from it onto active Dedicated Hosts in your account.
4. When you run these instances, depending on the operating system, you might be required to activate these instances against your own KMS server (for example, Windows Server or Windows SQL Server). You can't activate your imported Windows AMI against the Amazon Windows KMS server.

Note

To track how your images are used in AWS, enable host recording in AWS Config. You can use AWS Config to record configuration changes to a Dedicated Host and use the output as a data source for license reporting. For more information, see [Track configuration changes \(p. 497\)](#).

Pricing and billing

The price for a Dedicated Host varies by payment option.

Payment Options

- [On-Demand Dedicated Hosts \(p. 461\)](#)
- [Dedicated Host Reservations \(p. 461\)](#)
- [Savings Plans \(p. 462\)](#)
- [Pricing for Windows Server on Dedicated Hosts \(p. 462\)](#)

On-Demand Dedicated Hosts

On-Demand billing is automatically activated when you allocate a Dedicated Host to your account.

The On-Demand price for a Dedicated Host varies by instance family and Region. You pay per second (with a minimum of 60 seconds) for active Dedicated Host, regardless of the quantity or the size of instances that you choose to launch on it. For more information about On-Demand pricing, see [Amazon EC2 Dedicated Hosts On-Demand Pricing](#).

You can release an On-Demand Dedicated Host at any time to stop accruing charges for it. For information about releasing a Dedicated Host, see [Release Dedicated Hosts \(p. 478\)](#).

Dedicated Host Reservations

Dedicated Host Reservations provide a billing discount compared to running On-Demand Dedicated Hosts. Reservations are available in three payment options:

- **No Upfront**—No Upfront Reservations provide you with a discount on your Dedicated Host usage over a term and do not require an upfront payment. Available in one-year and three-year terms. Only some instance families support the three-year term for No Upfront Reservations.
- **Partial Upfront**—A portion of the reservation must be paid upfront and the remaining hours in the term are billed at a discounted rate. Available in one-year and three-year terms.
- **All Upfront**—Provides the lowest effective price. Available in one-year and three-year terms and covers the entire cost of the term upfront, with no additional future charges.

You must have active Dedicated Hosts in your account before you can purchase reservations. Each reservation can cover one or more hosts that support the same instance family in a single Availability Zone. Reservations are applied to the instance family on the host, not the instance size. If you have three Dedicated Hosts with different instances sizes (m4.xlarge, m4.medium, and m4.large) you can associate a single m4 reservation with all those Dedicated Hosts. The instance family and Availability Zone of the reservation must match that of the Dedicated Hosts you want to associate it with.

When a reservation is associated with a Dedicated Host, the Dedicated Host can't be released until the reservation's term is over.

For more information about reservation pricing, see [Amazon EC2 Dedicated Hosts Pricing](#).

Savings Plans

Savings Plans are a flexible pricing model that offers significant savings over On-Demand Instances. With Savings Plans, you make a commitment to a consistent amount of usage, in USD per hour, for a term of one or three years. This provides you with the flexibility to use the Dedicated Hosts that best meet your needs and continue to save money, instead of making a commitment to a specific Dedicated Host. For more information, see the [AWS Savings Plans User Guide](#).

Note

Savings Plans are not supported with u-6tb1.metal, u-9tb1.metal, u-12tb1.metal, u-18tb1.metal, and u-24tb1.metal Dedicated Hosts.

Pricing for Windows Server on Dedicated Hosts

Subject to Microsoft licensing terms, you can bring your existing Windows Server and SQL Server licenses to Dedicated Hosts. There is no additional charge for software usage if you choose to bring your own licenses.

In addition, you can also use Windows Server AMIs provided by Amazon to run the latest versions of Windows Server on Dedicated Hosts. This is common for scenarios where you have existing SQL Server licenses eligible to run on Dedicated Hosts, but need Windows Server to run the SQL Server workload. Windows Server AMIs provided by Amazon are supported on [current generation instance types \(p. 212\)](#). For more information, see [Amazon EC2 Dedicated Hosts Pricing](#).

Burstable T3 instances on Dedicated Hosts

Dedicated Hosts support burstable performance T3 instances. T3 instances provide a cost-efficient way of using your eligible BYOL license software on dedicated hardware. The smaller vCPU footprint of T3 instances enables you to consolidate your workloads on fewer hosts and maximize your per-core license utilization.

T3 Dedicated Hosts are best suited for running BYOL software with low to moderate CPU utilization. This includes eligible per-socket, per-core, or per-VM software licenses, such as Windows Server, Windows Desktop, SQL Server, SUSE Enterprise Linux Server, Red Hat Enterprise Linux, and Oracle Database. Examples of workloads suited for T3 Dedicated Hosts are small and medium databases, virtual desktops, development and test environments, code repositories, and product prototypes. T3 Dedicated Hosts are not recommended for workloads with sustained high CPU utilization or for workloads that experience correlated CPU bursts simultaneously.

T3 instances on Dedicated Hosts use the same credit model as T3 instances on shared tenancy hardware. However, they support the standard credit mode only; they do not support the unlimited credit mode. In standard mode, T3 instances on Dedicated Hosts *earn*, *spend*, and *accrue* credits in the same way as burstable instances on shared tenancy hardware. They provide a baseline CPU performance with the ability to burst above the baseline level. To burst above the baseline, the instance spends credits that it has accrued in its CPU credit balance. When the accrued credits are depleted, CPU utilization is lowered to the baseline level. For more information about standard mode, see [How standard burstable performance instances work \(p. 261\)](#).

T3 Dedicated Hosts support all of the features offered by Amazon EC2 Dedicated Hosts, including multiple instance sizes on a single host, Host resource groups, and BYOL.

Supported T3 instance sizes and configurations

T3 Dedicated Hosts run general purpose burstable T3 instances that share CPU resources of the host by providing a baseline CPU performance and the ability to burst to a higher level when needed. This

enables T3 Dedicated Hosts, which have 48 cores, to support up to a maximum of 192 instances per host. In order to efficiently utilize the host's resources and to provide the best instance performance, the Amazon EC2 instance placement algorithm automatically calculates the supported number of instances and instance size combinations that can be launched on the host.

T3 Dedicated Hosts support multiple instance types on the same host. All T3 instance sizes are supported on Dedicated Hosts. You can run different combinations of T3 instances up to the CPU limit of the host.

The following table lists the supported instance types, summarizes the performance of each instance type, and indicates the maximum number of instances of each size that can be launched.

Instance type	vCPUs	Memory (GiB)	Baseline CPU utilization per vCPU	Network burst bandwidth (Gbps)	Amazon EBS burst bandwidth (Mbps)	Max number of instances per Dedicated Host
t3.nano	0.5	5%	5	Up to 2,085	192	
t3.micro	1	10%	5	Up to 2,085	192	
t3.small	2	20%	5	Up to 2,085	192	
t3.medium	4	20%	5	Up to 2,085	192	
t3.large	8	30%	5	2,780	96	
t3.xlarge	16	40%	5	2,780	48	
t3.2xlarge	32	40%	5	2,780	24	

Monitor CPU utilization for T3 Dedicated Hosts

You can use the `DedicatedHostCPUUtilization` Amazon CloudWatch metric to monitor the vCPU utilization of a Dedicated Host. The metric is available in the EC2 namespace and `Per-Host-Metrics` dimension. For more information, see [Dedicated Host metrics \(p. 1190\)](#).

Dedicated Hosts restrictions

Before you allocate Dedicated Hosts, take note of the following limitations and restrictions:

- To run RHEL, SUSE Linux, and SQL Server on Dedicated Hosts, you must bring your own AMIs. RHEL, SUSE Linux, and SQL Server AMIs that are offered by AWS or that are available on AWS Marketplace can't be used with Dedicated Hosts. For more information on how to create your own AMI, see [Bring your own license \(p. 460\)](#).

This restriction does not apply to hosts allocated for high memory instances (`u-6tb1.metal`, `u-9tb1.metal`, `u-12tb1.metal`, `u-18tb1.metal`, and `u-24tb1.metal`). RHEL and SUSE Linux AMIs that are offered by AWS or that are available on AWS Marketplace can be used with these hosts.

- There is a limit on the number of running Dedicated Hosts per instance family per AWS account per Region. Quotas apply to running instances only. If your instance is pending, stopping, stopped, or hibernated, it does not count towards your quota. To view the quotas for your account, or to request a quota increase, use the [Service Quotas console](#).
- The instances that run on a Dedicated Host can only be launched in a VPC.
- Auto Scaling groups are supported when using a launch template that specifies a host resource group. For more information, see [Creating a Launch Template for an Auto Scaling Group](#) in the *Amazon EC2 Auto Scaling User Guide*.

- Amazon RDS instances are not supported.
- The AWS Free Usage tier is not available for Dedicated Hosts.
- Instance placement control refers to managing instance launches onto Dedicated Hosts. You cannot launch Dedicated Hosts into placement groups.
- If you allocate a host for a virtualized instance type, you can't modify the instance type to a .metal instance type after the host is allocated. For example, if you allocate a host for the m5.large instance type, you can't modify the instance type to m5.metal.

Similarly, if you allocate a host for a .metal instance type, you can't modify the instance type to a virtualized instance type after the host is allocated. For example, if you allocate a host for the m5.metal instance type, you can't modify the instance type to m5.large.

Work with Dedicated Hosts

To use a Dedicated Host, you first allocate hosts for use in your account. You then launch instances onto the hosts by specifying *host* tenancy for the instance. You must select a specific host for the instance to launch on to, or you can allow it to launch on to any host that has auto-placement enabled and matches its instance type. When an instance is stopped and restarted, the *Host affinity* setting determines whether it's restarted on the same, or a different, host.

If you no longer need an On-Demand host, you can stop the instances running on the host, direct them to launch on a different host, and then *release* the host.

Dedicated Hosts are also integrated with AWS License Manager. With License Manager, you can create a host resource group, which is a collection of Dedicated Hosts that are managed as a single entity. When creating a host resource group, you specify the host management preferences, such as auto-allocate and auto-release, for the Dedicated Hosts. This allows you to launch instances onto Dedicated Hosts without manually allocating and managing those hosts. For more information, see [Host Resource Groups](#) in the *AWS License Manager User Guide*.

Contents

Allocate Dedicated Hosts

To begin using Dedicated Hosts, you must allocate Dedicated Hosts in your account using the Amazon EC2 console or the command line tools. After you allocate the Dedicated Host, the Dedicated Host

capacity is made available in your account immediately and you can start launching instances onto the Dedicated Host.

When you allocate a Dedicated Host in your account, you can choose a configuration that supports either a **single instance type**, or **multiple instance types** within the same instance family. The number of instances that you can run on the host depends on the configuration you choose. For more information see [Instance capacity configurations \(p. 458\)](#).

New console

To allocate a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts** and then choose **Allocate Dedicated Host**.
3. For **Instance family**, choose the instance family for the Dedicated Host.
4. Specify whether the Dedicated Host supports multiple instance sizes within the selected instance family, or a specific instance type only. Do one of the following.
 - To configure the Dedicated Host to support multiple instance types in the selected instance family, for **Support multiple instance types**, choose **Enable**. Enabling this allows you to launch different instance sizes from the same instance family onto the Dedicated Host. For example, if you choose the m5 instance family and choose this option, you can launch m5.xlarge and m5.4xlarge instances onto the Dedicated Host.
 - To configure the Dedicated Host to support a single instance type within the selected instance family, clear **Support multiple instance types**, and then for **Instance type**, choose the instance type to support. This allows you to launch a single instance type on the Dedicated Host. For example, if you choose this option and specify m5.4xlarge as the supported instance type, you can launch only m5.4xlarge instances onto the Dedicated Host.
5. For **Availability Zone**, choose the Availability Zone in which to allocate the Dedicated Host.
6. To allow the Dedicated Host to accept untargeted instance launches that match its instance type, for **Instance auto-placement**, choose **Enable**. For more information about auto-placement, see [Understand auto-placement and affinity \(p. 470\)](#).
7. To enable host recovery for the Dedicated Host, for **Host recovery**, choose **Enable**. For more information, see [Host recovery \(p. 488\)](#).
8. For **Quantity**, enter the number of Dedicated Hosts to allocate.
9. (Optional) Choose **Add new tag** and enter a tag key and a tag value.
10. Choose **Allocate**.

Old console

To allocate a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**, **Allocate Dedicated Host**.
3. For **Instance family**, choose the instance family for the Dedicated Host.
4. Specify whether the Dedicated Host supports multiple instance sizes within the selected instance family, or a specific instance type only. Do one of the following.
 - To configure the Dedicated Host to support multiple instance types in the selected instance family, select **Support multiple instance types**. Enabling this allows you to launch different instance sizes from the same instance family onto the Dedicated Host. For example, if you choose the m5 instance family and choose this option, you can launch m5.xlarge and m5.4xlarge instances onto the Dedicated Host. The instance family must be powered by the Nitro System.

- To configure the Dedicated Host to support a single instance type within the selected instance family, clear **Support multiple instance types**, and then for **Instance type**, choose the instance type to support. This allows you to launch a single instance type on the Dedicated Host. For example, if you choose this option and specify m5.4xlarge as the supported instance type, you can launch only m5.4xlarge instances onto the Dedicated Host.
- For **Availability Zone**, choose the Availability Zone in which to allocate the Dedicated Host.
 - To allow the Dedicated Host to accept untargeted instance launches that match its instance type, for **Instance auto-placement**, choose **Enable**. For more information about auto-placement, see [Understand auto-placement and affinity \(p. 470\)](#).
 - To enable host recovery for the Dedicated Host, for **Host recovery** choose **Enable**. For more information, see [Host recovery \(p. 488\)](#).
 - For **Quantity**, enter the number of Dedicated Hosts to allocate.
 - (Optional) Choose **Add Tag** and enter a tag key and a tag value.
 - Choose **Allocate host**.

AWS CLI

To allocate a Dedicated Host

Use the [allocate-hosts](#) AWS CLI command. The following command allocates a Dedicated Host that supports multiple instance types from the m5 instance family in us-east-1a Availability Zone. The host also has host recovery enabled and it has auto-placement disabled.

```
aws ec2 allocate-hosts --instance-family "m5" --availability-zone "us-east-1a" --auto-placement "off" --host-recovery "on" --quantity 1
```

The following command allocates a Dedicated Host that supports *untargeted* m4.large instance launches in the eu-west-1a Availability Zone, enables host recovery, and applies a tag with a key of *purpose* and a value of *production*.

```
aws ec2 allocate-hosts --instance-type "m4.large" --availability-zone "eu-west-1a" --auto-placement "on" --host-recovery "on" --quantity 1 --tag-specifications 'ResourceType=dedicated-host,Tags=[{Key=purpose,Value=production}]'
```

PowerShell

To allocate a Dedicated Host

Use the [New-EC2Host](#) AWS Tools for Windows PowerShell command. The following command allocates a Dedicated Host that supports multiple instance types from the m5 instance family in us-east-1a Availability Zone. The host also has host recovery enabled and it has auto-placement disabled.

```
PS C:\> New-EC2Host -InstanceFamily m5 -AvailabilityZone us-east-1a -AutoPlacement Off -HostRecovery On -Quantity 1
```

The following commands allocate a Dedicated Host that supports *untargeted* m4.large instance launches in the eu-west-1a Availability Zone, enable host recovery, and apply a tag with a key of *purpose* and a value of *production*.

The **TagSpecification** parameter used to tag a Dedicated Host on creation requires an object that specifies the type of resource to be tagged, the tag key, and the tag value. The following commands create the required object.

```
PS C:\> $tag = @{ Key="purpose"; Value="production" }
```

```
PS C:\> $tagspec = new-object Amazon.EC2.Model.TagSpecification
PS C:\> $tagspec.ResourceType = "dedicated-host"
PS C:\> $tagspec.Tags.Add($tag)
```

The following command allocates the Dedicated Host and applies the tag specified in the \$tagspec object.

```
PS C:\> New-EC2Host -InstanceType m4.large -AvailabilityZone eu-west-1a -
AutoPlacement On -HostRecovery On -Quantity 1 -TagSpecification $tagspec
```

Launch instances onto a Dedicated Host

After you have allocated a Dedicated Host, you can launch instances onto it. You can't launch instances with host tenancy if you do not have active Dedicated Hosts with enough available capacity for the instance type that you are launching.

Tip

For Dedicated Hosts that support multiple instance sizes, we recommend that you launch the larger instance sizes first, and then fill the remaining instance capacity with the smaller instance sizes as needed.

Before you launch your instances, take note of the limitations. For more information, see [Dedicated Hosts restrictions \(p. 463\)](#).

You can launch an instance onto a Dedicated Host using the following methods.

Console

To launch an instance onto a specific Dedicated Host from the Dedicated Hosts page

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Dedicated Hosts** in the navigation pane.
3. On the **Dedicated Hosts** page, select a host and choose **Actions, Launch Instance(s) onto host**.
4. In the **Application and OS Images** section, select an AMI from the list.

Note

SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.

5. In the **Instance type** section, select the instance type to launch.

Note

If the Dedicated Host supports a single instance type only, the supported instance type is selected by default and can't be changed.

If the Dedicated Host supports multiple instance types, you must select an instance type within the supported instance family based on the available instance capacity of the Dedicated Host. We recommend that you launch the larger instance sizes first, and then fill the remaining instance capacity with the smaller instance sizes as needed.

6. In the **Key pair** section, select the key pair to associate with the instance.
7. In the **Advanced details** section, for **Tenancy affinity**, do one of the following:
 - Select **Off** — The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
 - Select the Dedicated Host ID — If stopped, the instance always restarts on this specific host.

For more information about Affinity, see [Understand auto-placement and affinity \(p. 470\)](#).

Note

The **Tenancy** and **Host** options are pre-configured based on the host that you selected.

8. Configure the remaining instance options as needed. For more information, see [Launch an instance using defined parameters \(p. 554\)](#).
9. Choose **Launch instance**.

To launch an instance onto a Dedicated Host using the Launch Instance wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, **Launch instance**.
3. In the **Application and OS Images** section, select an AMI from the list.

Note

SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.

4. In the **Instance type** section, select the instance type to launch.
5. In the **Key pair** section, select the key pair to associate with the instance.
6. In the **Advanced details** section, do the following:
 - a. For **Tenancy**, select **Dedicated Host**.
 - b. For **Target host by**, select **Host ID**.
 - c. For **Target host ID**, select the host onto which to launch the instance.
 - d. For **Tenancy affinity**, do one of the following:
 - Select **Off** — The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
 - Select the Dedicated Host ID — If stopped, the instance always restarts on this specific host.

For more information about Affinity, see [Understand auto-placement and affinity \(p. 470\)](#).

7. Configure the remaining instance options as needed. For more information, see [Launch an instance using defined parameters \(p. 554\)](#).
8. Choose **Launch instance**.

AWS CLI

To launch an instance onto a Dedicated Host

Use the [run-instances](#) AWS CLI command and specify the instance affinity, tenancy, and host in the Placement request parameter.

PowerShell

To launch an instance onto a Dedicated Host

Use the [New-EC2Instance](#) AWS Tools for Windows PowerShell command and specify the instance affinity, tenancy, and host in the Placement request parameter.

Launch instances into a host resource group

When you launch an instance into a host resource group that has a Dedicated Host with available instance capacity, Amazon EC2 launches the instance onto that host. If the host resource group does not

have a host with available instance capacity, Amazon EC2 automatically allocates a new host in the host resource group, and then launches the instance onto that host. For more information, see [Host Resource Groups](#) in the *AWS License Manager User Guide*.

Requirements and limits

- You must associate a core- or socket-based license configuration with the AMI.
- You can't use SQL Server, SUSE, or RHEL AMIs provided by Amazon EC2 with Dedicated Hosts.
- You can't target a specific host by choosing a host ID, and you can't enable instance affinity when launching an instance into a host resource group.

You can launch an instance into a host resource group using the following methods.

Console

To launch an instance into a host resource group

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, **Launch instance**.
3. In the **Application and OS Images** section, select an AMI from the list.

Note

SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.

4. In the **Instance type** section, select the instance type to launch.
5. In the **Key pair** section, select the key pair to associate with the instance.
6. In the **Advanced details** section, do the following:
 - a. For **Tenancy**, select **Dedicated Host**.
 - b. For **Target host by**, select **Host resource group**.
 - c. For **Tenancy host resource group**, select the host resource group into which to launch the instance.
 - d. For **Tenancy affinity**, do one of the following:
 - Select **Off** — The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
 - Select the Dedicated Host ID — If stopped, the instance always restarts on this specific host.

For more information about Affinity, see [Understand auto-placement and affinity \(p. 470\)](#).

7. Configure the remaining instance options as needed. For more information, see [Launch an instance using defined parameters \(p. 554\)](#).
8. Choose **Launch instance**.

AWS CLI

To launch an instance into a host resource group

Use the [run-instances](#) AWS CLI command, and in the Placement request parameter, omit the Tenancy option and specify the host resource group ARN.

PowerShell

To launch an instance into a host resource group

Use the [New-EC2Instance](#) AWS Tools for Windows PowerShell command, and in the Placement request parameter, omit the Tenancy option and specify the host resource group ARN.

Understand auto-placement and affinity

Placement control for Dedicated Hosts happens on both the instance level and host level.

Auto-placement

Auto-placement is configured at the host level. It allows you to manage whether instances that you launch are launched onto a specific host, or onto any available host that has matching configurations.

When the auto-placement of a Dedicated Host is *disabled*, it only accepts *Host* tenancy instance launches that specify its unique host ID. This is the default setting for new Dedicated Hosts.

When the auto-placement of a Dedicated Host is *enabled*, it accepts any untargeted instance launches that match its instance type configuration.

When launching an instance, you need to configure its tenancy. Launching an instance onto a Dedicated Host without providing a specific HostId enables it to launch on any Dedicated Host that has auto-placement *enabled* and that matches its instance type.

Host affinity

Host affinity is configured at the instance level. It establishes a launch relationship between an instance and a Dedicated Host.

When affinity is set to *Host*, an instance launched onto a specific host always restarts on the same host if stopped. This applies to both targeted and untargeted launches.

When affinity is set to *Off*, and you stop and restart the instance, it can be restarted on any available host. However, it tries to launch back onto the last Dedicated Host on which it ran (on a best-effort basis).

Modify Dedicated Host auto-placement

You can modify the auto-placement settings of a Dedicated Host after you have allocated it to your AWS account, using one of the following methods.

New console

To modify the auto-placement of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select a host and choose **Actions, Modify host**.
4. For **Instance auto-placement**, choose **Enable** to enable auto-placement, or clear **Enable** to disable auto-placement. For more information, see [Understand auto-placement and affinity \(p. 470\)](#).
5. Choose **Save**.

Old console

To modify the auto-placement of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. Choose **Dedicated Hosts** in the navigation pane.
3. On the **Dedicated Hosts** page, select a host and choose **Actions, Modify Auto-Placement**.
4. On the Modify Auto-placement window, for **Allow instance auto-placement**, choose **Yes** to enable auto-placement, or choose **No** to disable auto-placement. For more information, see [Understand auto-placement and affinity \(p. 470\)](#).
5. Choose **Save**.

AWS CLI

To modify the auto-placement of a Dedicated Host

Use the [modify-hosts](#) AWS CLI command. The following example enables auto-placement for the specified Dedicated Host.

```
aws ec2 modify-hosts --auto-placement on --host-ids h-012a3456b7890cdef
```

PowerShell

To modify the auto-placement of a Dedicated Host

Use the [Edit-EC2Host](#) AWS Tools for Windows PowerShell command. The following example enables auto-placement for the specified Dedicated Host.

```
PS C:\> Edit-EC2Host --AutoPlacement 1 --HostId h-012a3456b7890cdef
```

Modify the supported instance types

Support for multiple instance types on the same Dedicated Host is available for the following instance families: C5, M5, R5, C5n, R5n, M5n, and T3. Other instance families support only a single instance type on the same Dedicated Host.

You can allocate a Dedicated Host using the following methods.

You can modify a Dedicated Host to change the instance types that it supports. If it currently supports a single instance type, you can modify it to support multiple instance types within that instance family. Similarly, if it currently supports multiple instance types, you can modify it to support a specific instance type only.

To modify a Dedicated Host to support multiple instance types, you must first stop all running instances on the host. The modification takes approximately 10 minutes to complete. The Dedicated Host transitions to the pending state while the modification is in progress. You can't start stopped instances or launch new instances on the Dedicated Host while it is in the pending state.

To modify a Dedicated Host that supports multiple instance types to support only a single instance type, the host must either have no running instances, or the running instances must be of the instance type that you want the host to support. For example, to modify a host that supports multiple instance types in the m5 instance family to support only m5.large instances, the Dedicated Host must either have no running instances, or it must have only m5.large instances running on it.

If you allocate a host for a virtualized instance type, you can't modify the instance type to a .metal instance type after the host is allocated. For example, if you allocate a host for the m5.large instance type, you can't modify the instance type to m5.metal. Similarly, if you allocate a host for a .metal instance type, you can't modify the instance type to a virtualized instance type after the host is allocated. For example, if you allocate a host for the m5.metal instance type, you can't modify the instance type to m5.large.

You can modify the supported instance types using one of the following methods.

New console

To modify the supported instance types for a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the Navigation pane, choose **Dedicated Host**.
3. Select the Dedicated Host to modify and choose **Actions, Modify host**.
4. Do one of the following, depending on the current configuration of the Dedicated Host:
 - If the Dedicated Host currently supports a specific instance type, **Support multiple instance types** is not enabled, and **Instance type** lists the supported instance type. To modify the host to support multiple types in the current instance family, for **Support multiple instance types**, choose **Enable**.

You must first stop all instances running on the host before modifying it to support multiple instance types.

- If the Dedicated Host currently supports multiple instance types in an instance family, **Enabled** is selected for **Support multiple instance types**. To modify the host to support a specific instance type, for **Support multiple instance types**, clear **Enable**, and then for **Instance type**, select the specific instance type to support.

You can't change the instance family supported by the Dedicated Host.

5. Choose **Save**.

Old console

To modify the supported instance types for a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the Navigation pane, choose **Dedicated Host**.
3. Select the Dedicated Host to modify and choose **Actions, Modify Supported Instance Types**.
4. Do one of the following, depending on the current configuration of the Dedicated Host:
 - If the Dedicated Host currently supports a specific instance type, **No** is selected for **Support multiple instance types**. To modify the host to support multiple types in the current instance family, for **Support multiple instance types**, select **Yes**.

You must first stop all instances running on the host before modifying it to support multiple instance types.

- If the Dedicated Host currently supports multiple instance types in an instance family, **Yes** is selected for **Support multiple instance types**, and **Instance family** displays the supported instance family. To modify the host to support a specific instance type, for **Support multiple instance types**, select **No**, and then for **Instance type**, select the specific instance type to support.

You can't change the instance family supported by the Dedicated Host.

5. Choose **Save**.

AWS CLI

To modify the supported instance types for a Dedicated Host

Use the [modify-hosts](#) AWS CLI command.

The following command modifies a Dedicated Host to support multiple instance types within the m5 instance family.

```
aws ec2 modify-hosts --instance-family m5 --host-ids h-012a3456b7890cdef
```

The following command modifies a Dedicated Host to support m5.xlarge instances only.

```
aws ec2 modify-hosts --instance-type m5.xlarge --instance-family --host-ids h-012a3456b7890cdef
```

PowerShell

To modify the supported instance types for a Dedicated Host

Use the [Edit-EC2Host](#) AWS Tools for Windows PowerShell command.

The following command modifies a Dedicated Host to support multiple instance types within the m5 instance family.

```
PS C:\> Edit-EC2Host --InstanceFamily m5 --HostId h-012a3456b7890cdef
```

The following command modifies a Dedicated Host to support m5.xlarge instances only.

```
PS C:\> Edit-EC2Host --InstanceType m5.xlarge --HostId h-012a3456b7890cdef
```

Modify instance tenancy and affinity

You can change the tenancy of an instance after you have launched it. You can also modify the affinity between the instance and the host. To modify either instance tenancy or affinity, the instance must be in the stopped state.

Note

For T3 instances, you can't change the tenancy from dedicated to host, or from host to dedicated. Attempting to make one of these unsupported tenancy changes results in the InvalidTenancy error code.

You can modify an instance's tenancy and affinity using the following methods.

Console

To modify instance tenancy or affinity

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Instances**, and select the instance to modify.
3. Choose **Instance state, Stop**.
4. Open the context (right-click) menu on the instance and choose **Instance Settings, Modify Instance Placement**.
5. On the **Modify Instance Placement** page, configure the following:
 - **Tenancy**—Choose one of the following:
 - Run a dedicated hardware instance—Launches the instance as a Dedicated Instance. For more information, see [Dedicated Instances \(p. 499\)](#).
 - Launch the instance on a Dedicated Host—Launches the instance onto a Dedicated Host with configurable affinity.

- **Affinity**—Choose one of the following:
 - This instance can run on any one of my hosts—The instance launches onto any available Dedicated Host in your account that supports its instance type.
 - This instance can only run on the selected host—The instance is only able to run on the Dedicated Host selected for **Target Host**.
- **Target Host**—Select the Dedicated Host that the instance must run on. If no target host is listed, you might not have available, compatible Dedicated Hosts in your account.

For more information, see [Understand auto-placement and affinity \(p. 470\)](#).

6. Choose **Save**.

AWS CLI

To modify instance tenancy or affinity

Use the [modify-instance-placement](#) AWS CLI command. The following example changes the specified instance's affinity from default to host, and specifies the Dedicated Host that the instance has affinity with.

```
aws ec2 modify-instance-placement --instance-id i-1234567890abcdef0 --affinity host --  
host-id h-012a3456b7890cdef
```

PowerShell

To modify instance tenancy or affinity

Use the [Edit-EC2InstancePlacement](#) AWS Tools for Windows PowerShell command. The following example changes the specified instance's affinity from default to host, and specifies the Dedicated Host that the instance has affinity with.

```
PS C:\> Edit-EC2InstancePlacement -InstanceId i-1234567890abcdef0 -Affinity host -  
HostId h-012a3456b7890cdef
```

View Dedicated Hosts

You can view details about a Dedicated Host and the individual instances on it using the following methods.

New console

To view the details of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. On the **Dedicated Hosts** page, select a host.
4. For information about the host, choose **Details**.

Available vCPUs indicates the vCPUs that are available on the Dedicated Host for new instance launches. For example, a Dedicated Host that supports multiple instance types within the c5 instance family, and that has no instances running on it, has 72 available vCPUs. This means that you can launch different combinations of instance types onto the Dedicated Host to consume the 72 available vCPUs.

For information about instances running on the host, choose **Running instances**.

Old console

To view the details of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. On the **Dedicated Hosts** page, select a host.
4. For information about the host, choose **Description**. **Available vCPUs** indicates the vCPUs that are available on the Dedicated Host for new instance launches. For example, a Dedicated Host that supports multiple instance types within the c5 instance family, and that has no instances running on it, has 72 available vCPUs. This means that you can launch different combinations of instance types onto the Dedicated Host to consume the 72 available vCPUs.

For information about instances running on the host, choose **Instances**.

AWS CLI

To view the capacity of a Dedicated Host

Use the [describe-hosts](#) AWS CLI command.

The following example uses the [describe-hosts](#) (AWS CLI) command to view the available instance capacity for a Dedicated Host that supports multiple instance types within the c5 instance family. The Dedicated Host already has two c5.4xlarge instances and four c5.2xlarge instances running on it.

```
C:\> aws ec2 describe-hosts --host-id h-012a3456b7890cdef
```

```
"AvailableInstanceCapacity": [  
    { "AvailableCapacity": 2,  
      "InstanceType": "c5.xlarge",  
      "TotalCapacity": 18 },  
    { "AvailableCapacity": 4,  
      "InstanceType": "c5.large",  
      "TotalCapacity": 36 }  
],  
"AvailableVCpus": 8
```

PowerShell

To view the instance capacity of a Dedicated Host

Use the [Get-EC2Host](#) AWS Tools for Windows PowerShell command.

```
PS C:\> Get-EC2Host -HostId h-012a3456b7890cdef
```

Tag Dedicated Hosts

You can assign custom tags to your existing Dedicated Hosts to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to quickly find a specific Dedicated Host based on the custom tags that you assigned. Dedicated Host tags can also be used for cost allocation tracking.

You can also apply tags to Dedicated Hosts at the time of creation. For more information, see [Allocate Dedicated Hosts \(p. 464\)](#).

You can tag a Dedicated Host using the following methods.

New console

To tag a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host to tag, and then choose **Actions, Manage tags**.
4. In the **Manage tags** screen, choose **Add tag**, and then specify the key and value for the tag.
5. (Optional) Choose **Add tag** to add additional tags to the Dedicated Host.
6. Choose **Save changes**.

Old console

To tag a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host to tag, and then choose **Tags**.
4. Choose **Add/Edit Tags**.
5. In the **Add/Edit Tags** dialog box, choose **Create Tag**, and then specify the key and value for the tag.
6. (Optional) Choose **Create Tag** to add additional tags to the Dedicated Host.
7. Choose **Save**.

AWS CLI

To tag a Dedicated Host

Use the [create-tags](#) AWS CLI command.

The following command tags the specified Dedicated Host with Owner=TeamA.

```
aws ec2 create-tags --resources h-abc12345678909876 --tags Key=Owner,Value=TeamA
```

PowerShell

To tag a Dedicated Host

Use the [New-EC2Tag](#) AWS Tools for Windows PowerShell command.

The New-EC2Tag command needs a Tag object, which specifies the key and value pair to be used for the Dedicated Host tag. The following commands create a Tag object named \$tag, with a key and value pair of Owner and TeamA respectively.

```
PS C:\> $tag = New-Object Amazon.EC2.Model.Tag
PS C:\> $tag.Key = "Owner"
PS C:\> $tag.Value = "TeamA"
```

The following command tags the specified Dedicated Host with the \$tag object.

```
PS C:\> New-EC2Tag -Resource h-abc12345678909876 -Tag $tag
```

Monitor Dedicated Hosts

Amazon EC2 constantly monitors the state of your Dedicated Hosts. Updates are communicated on the Amazon EC2 console. You can view information about a Dedicated Host using the following methods.

Console

To view the state of a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Locate the Dedicated Host in the list and review the value in the **State** column.

AWS CLI

To view the state of a Dedicated Host

Use the [describe-hosts](#) AWS CLI command and then review the state property in the hostSet response element.

```
aws ec2 describe-hosts --host-id h-012a3456b7890cdef
```

PowerShell

To view the state of a Dedicated Host

Use the [Get-EC2Host](#) AWS Tools for Windows PowerShell command and then review the state property in the hostSet response element.

```
PS C:\> Get-EC2Host -HostId h-012a3456b7890cdef
```

The following table explains the possible Dedicated Host states.

State	Description
available	AWS hasn't detected an issue with the Dedicated Host. No maintenance or repairs are scheduled. Instances can be launched onto this Dedicated Host.
released	The Dedicated Host has been released. The host ID is no longer in use. Released hosts can't be reused.
under-assessment	AWS is exploring a possible issue with the Dedicated Host. If action must be taken, you are notified via the AWS Management Console or email. Instances can't be launched onto a Dedicated Host in this state.
pending	The Dedicated Host cannot be used for new instance launches. It is either being modified to support multiple instance types (p. 471) , or a host recovery (p. 488) is in progress.

State	Description
permanent-failure	An unrecoverable failure has been detected. You receive an eviction notice through your instances and by email. Your instances might continue to run. If you stop or terminate all instances on a Dedicated Host with this state, AWS retires the host. AWS does not restart instances in this state. Instances can't be launched onto Dedicated Hosts in this state.
released-permanent-failure	AWS permanently releases Dedicated Hosts that have failed and no longer have running instances on them. The Dedicated Host ID is no longer available for use.

Release Dedicated Hosts

Any running instances on the Dedicated Host must be stopped before you can release the host. These instances can be migrated to other Dedicated Hosts in your account so that you can continue to use them. These steps apply only to On-Demand Dedicated Hosts.

You can release a Dedicated Host using the following methods.

New console

To release a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. On the **Dedicated Hosts** page, select the Dedicated Host to release.
4. Choose **Actions, Release host**.
5. To confirm, choose **Release**.

Old console

To release a Dedicated Host

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Dedicated Hosts** in the navigation pane.
3. On the **Dedicated Hosts** page, select the Dedicated Host to release.
4. Choose **Actions, Release Hosts**.
5. Choose **Release** to confirm.

AWS CLI

To release a Dedicated Host

Use the [release-hosts](#) AWS CLI command.

```
aws ec2 release-hosts --host-ids h-012a3456b7890cdef
```

PowerShell

To release a Dedicated Host

Use the [Remove-EC2Hosts](#) AWS Tools for Windows PowerShell command.

```
PS C:\> Remove-EC2Hosts -HostId h-012a3456b7890cdef
```

After you release a Dedicated Host, you can't reuse the same host or host ID again, and you are no longer charged On-Demand billing rates for it. The state of the Dedicated Host is changed to `released`, and you are not able to launch any instances onto that host.

Note

If you have recently released Dedicated Hosts, it can take some time for them to stop counting towards your limit. During this time, you might experience `LimitExceeded` errors when trying to allocate new Dedicated Hosts. If this is the case, try allocating new hosts again after a few minutes.

The instances that were stopped are still available for use and are listed on the **Instances** page. They retain their host tenancy setting.

Purchase Dedicated Host Reservations

You can purchase reservations using the following methods:

Console

To purchase reservations

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Dedicated Hosts, Dedicated Host Reservations, Purchase Dedicated Host Reservation**.
3. On the **Purchase Dedicated Host Reservation** screen, you can search for available offerings using the default settings, or you can specify custom values for the following:
 - **Host instance family**—The options listed correspond with the Dedicated Hosts in your account that are not already assigned to a reservation.
 - **Availability Zone**—The Availability Zone of the Dedicated Hosts in your account that aren't already assigned to a reservation.
 - **Payment option**—The payment option for the offering.
 - **Term**—The term of the reservation, which can be one or three years.
4. Choose **Find offering** and select an offering that matches your requirements.
5. Choose the Dedicated Hosts to associate with the reservation, and then choose **Review**.
6. Review your order and choose **Order**.

AWS CLI

To purchase reservations

1. Use the `describe-host-reservation-offerings` AWS CLI command to list the available offerings that match your needs. The following example lists the offerings that support instances in the `m4` instance family and have a one-year term.

Note

The term is specified in seconds. A one-year term includes 31,536,000 seconds, and a three-year term includes 94,608,000 seconds.

```
aws ec2 describe-host-reservation-offerings --filter Name=instance-family,Values=m4  
--max-duration 31536000
```

The command returns a list of offerings that match your criteria. Note the `offeringId` of the offering to purchase.

2. Use the [purchase-host-reservation](#) AWS CLI command to purchase the offering and provide the offeringId noted in the previous step. The following example purchases the specified reservation and associates it with a specific Dedicated Host that is already allocated in the AWS account, and it applies a tag with a key of purpose and a value of production.

```
aws ec2 purchase-host-reservation --offering-id hro-03f707bf363b6b324 --  
host-id-set h-013abcd2a00cbd123 --tag-specifications 'ResourceType=host-  
reservation,Tags=[{Key=purpose,Value=production}]'
```

PowerShell

To purchase reservations

1. Use the [Get-EC2HostReservationOffering](#) AWS Tools for Windows PowerShell command to list the available offerings that match your needs. The following examples list the offerings that support instances in the m4 instance family and have a one-year term.

Note

The term is specified in seconds. A one-year term includes 31,536,000 seconds, and a three-year term includes 94,608,000 seconds.

```
PS C:\> $filter = @{@Name="instance-family"; Value="m4"}
```

```
PS C:\> Get-EC2HostReservationOffering -filter $filter -MaxDuration 31536000
```

The command returns a list of offerings that match your criteria. Note the offeringId of the offering to purchase.

2. Use the [New-EC2HostReservation](#) AWS Tools for Windows PowerShell command to purchase the offering and provide the offeringId noted in the previous step. The following example purchases the specified reservation and associates it with a specific Dedicated Host that is already allocated in the AWS account.

```
PS C:\> New-EC2HostReservation -OfferingId hro-03f707bf363b6b324 -  
HostIdSet h-013abcd2a00cbd123
```

View Dedicated Host reservations

You can view information about the Dedicated Hosts that are associated with your reservation, including:

- The term of the reservation
- The payment option
- The start and end dates

You can view details of your Dedicated Host reservations using the following methods.

Console

To view the details of a Dedicated Host reservation

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Dedicated Hosts** in the navigation pane.
3. On the **Dedicated Hosts** page, choose **Dedicated Host Reservations**, and then select the reservation from the list provided.

4. Choose **Details** for information about the reservation.
5. Choose **Hosts** for information about the Dedicated Hosts with which the reservation is associated.

AWS CLI

To view the details of a Dedicated Host reservation

Use the [describe-host-reservations](#) AWS CLI command.

```
aws ec2 describe-host-reservations
```

PowerShell

To view the details of a Dedicated Host reservation

Use the [Get-EC2HostReservation](#) AWS Tools for Windows PowerShell command.

```
PS C:\> Get-EC2HostReservation
```

Tag Dedicated Host Reservations

You can assign custom tags to your Dedicated Host Reservations to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to quickly find a specific Dedicated Host Reservation based on the custom tags that you assigned.

You can tag a Dedicated Host Reservation using the command line tools only.

AWS CLI

To tag a Dedicated Host Reservation

Use the [create-tags](#) AWS CLI command.

```
aws ec2 create-tags --resources hr-1234563a4ffc669ae --tags Key=Owner,Value=TeamA
```

PowerShell

To tag a Dedicated Host Reservation

Use the [New-EC2Tag](#) AWS Tools for Windows PowerShell command.

The New-EC2Tag command needs a Tag parameter, which specifies the key and value pair to be used for the Dedicated Host Reservation tag. The following commands create the Tag parameter.

```
PS C:\> $tag = New-Object Amazon.EC2.Model.Tag
PS C:\> $tag.Key = "Owner"
PS C:\> $tag.Value = "TeamA"
```

```
PS C:\> New-EC2Tag -Resource hr-1234563a4ffc669ae -Tag $tag
```

Work with shared Dedicated Hosts

Dedicated Host sharing enables Dedicated Host owners to share their Dedicated Hosts with other AWS accounts or within an AWS organization. This enables you to create and manage Dedicated Hosts centrally, and share the Dedicated Host across multiple AWS accounts or within your AWS organization.

In this model, the AWS account that owns the Dedicated Host (*owner*) shares it with other AWS accounts (*consumers*). Consumers can launch instances onto Dedicated Hosts that are shared with them in the same way that they would launch instances onto Dedicated Hosts that they allocate in their own account. The owner is responsible for managing the Dedicated Host and the instances that they launch onto it. Owners can't modify instances that consumers launch onto shared Dedicated Hosts. Consumers are responsible for managing the instances that they launch onto Dedicated Hosts shared with them. Consumers can't view or modify instances owned by other consumers or by the Dedicated Host owner, and they can't modify Dedicated Hosts that are shared with them.

A Dedicated Host owner can share a Dedicated Host with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization
- Its entire AWS organization

Contents

- [Prerequisites for sharing Dedicated Hosts \(p. 482\)](#)
- [Limitations for sharing Dedicated Hosts \(p. 482\)](#)
- [Related services \(p. 482\)](#)
- [Share across Availability Zones \(p. 483\)](#)
- [Share a Dedicated Host \(p. 483\)](#)
- [Unshare a shared Dedicated Host \(p. 484\)](#)
- [Identify a shared Dedicated Host \(p. 485\)](#)
- [View instances running on a shared Dedicated Host \(p. 485\)](#)

- [Billing and metering \(p. 486\)](#)
- [Dedicated Host limits \(p. 486\)](#)
- [Host recovery and Dedicated Host sharing \(p. 486\)](#)

Prerequisites for sharing Dedicated Hosts

- To share a Dedicated Host, you must own it in your AWS account. You can't share a Dedicated Host that has been shared with you.
- To share a Dedicated Host with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see [Enable Sharing with AWS Organizations](#) in the *AWS RAM User Guide*.

Limitations for sharing Dedicated Hosts

You can't share Dedicated Hosts that have been allocated for the following instance types: u-6tb1.metal, u-9tb1.metal, u-12tb1.metal, u-18tb1.metal, and u-24tb1.metal.

Related services

AWS Resource Access Manager

Dedicated Host sharing integrates with AWS Resource Access Manager (AWS RAM). AWS RAM is a service that enables you to share your AWS resources with any AWS account or through AWS Organizations. With AWS RAM, you share resources that you own by creating a *resource share*. A resource share specifies

the resources to share, and the consumers with whom to share them. Consumers can be individual AWS accounts, or organizational units or an entire organization from AWS Organizations.

For more information about AWS RAM, see the [AWS RAM User Guide](#).

Share across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone `us-east-1a` for your AWS account might not have the same location as `us-east-1a` for another AWS account.

To identify the location of your Dedicated Hosts relative to your accounts, you must use the *Availability Zone ID* (AZ ID). The Availability Zone ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, `use1-az1` is an Availability Zone ID for the `us-east-1` Region and it is the same location in every AWS account.

To view the Availability Zone IDs for the Availability Zones in your account

1. Open the AWS RAM console at <https://console.aws.amazon.com/ram>.
2. The Availability Zone IDs for the current Region are displayed in the **Your AZ ID** panel on the right-hand side of the screen.

Share a Dedicated Host

When an owner shares a Dedicated Host, it enables consumers to launch instances on the host. Consumers can launch as many instances onto the shared host as its available capacity allows.

Important

Note that you are responsible for ensuring that you have appropriate license rights to share any BYOL licenses on your Dedicated Hosts.

If you share a Dedicated Host with auto-placement enabled, keep the following in mind as it could lead to unintended Dedicated Host usage:

- If consumers launch instances with Dedicated Host tenancy and they do not have capacity on a Dedicated Host that they own in their account, the instance is automatically launched onto the shared Dedicated Host.

To share a Dedicated Host, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared. You can add the Dedicated Host to an existing resource, or you can add it to a new resource share.

If you are part of an organization in AWS Organizations and sharing within your organization is enabled, consumers in your organization are automatically granted access to the shared Dedicated Host. Otherwise, consumers receive an invitation to join the resource share and are granted access to the shared Dedicated Host after accepting the invitation.

Note

After you share a Dedicated Host, it could take a few minutes for consumers to have access to it.

You can share a Dedicated Host that you own by using one of the following methods.

Amazon EC2 console

To share a Dedicated Host that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Dedicated Hosts**.
3. Choose the Dedicated Host to share and choose **Actions, Share host**.
4. Select the resource share to which to add the Dedicated Host and choose **Share host**.

It could take a few minutes for consumers to get access to the shared host.

AWS RAM console

To share a Dedicated Host that you own using the AWS RAM console

See [Creating a Resource Share](#) in the *AWS RAM User Guide*.

AWS CLI

To share a Dedicated Host that you own using the AWS CLI

Use the [create-resource-share](#) command.

Unshare a shared Dedicated Host

The Dedicated Host owner can unshare a shared Dedicated Host at any time. When you unshare a shared Dedicated Host, the following rules apply:

- Consumers with whom the Dedicated Host was shared can no longer launch new instances onto it.
- Instances owned by consumers that were running on the Dedicated Host at the time of unsharing continue to run but are scheduled for [retirement](#). Consumers receive retirement notifications for the instances and they have two weeks to take action on the notifications. However, if the Dedicated Host is reshared with the consumer within the retirement notice period, the instance retirements are cancelled.

To unshare a shared Dedicated Host that you own, you must remove it from the resource share. You can do this by using one of the following methods.

Amazon EC2 console

To unshare a shared Dedicated Host that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Choose the Dedicated Host to unshare and choose the **Sharing** tab.
4. The **Sharing** tab lists the resource shares to which the Dedicated Host has been added. Select the resource share from which to remove the Dedicated Host and choose **Remove host from resource share**.

AWS RAM console

To unshare a shared Dedicated Host that you own using the AWS RAM console

See [Updating a Resource Share](#) in the *AWS RAM User Guide*.

Command line

To unshare a shared Dedicated Host that you own using the AWS CLI

Use the [disassociate-resource-share](#) command.

Identify a shared Dedicated Host

Owners and consumers can identify shared Dedicated Hosts using one of the following methods.

Amazon EC2 console

To identify a shared Dedicated Host using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**. The screen lists Dedicated Hosts that you own and Dedicated Hosts that are shared with you. The **Owner** column shows the AWS account ID of the Dedicated Host owner.

Command line

To identify a shared Dedicated Host using the AWS CLI

Use the [describe-hosts](#) command. The command returns the Dedicated Hosts that you own and Dedicated Hosts that are shared with you.

View instances running on a shared Dedicated Host

Owners and consumers can view the instances running on a shared Dedicated Host at any time using one of the following methods.

Amazon EC2 console

To view the instances running on a shared Dedicated Host using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host for which to view the instances and choose **Instances**. The tab lists the instances that are running on the host. Owners see all of the instances running on the host, including instances launched by consumers. Consumers only see running instances that they launched onto the host. The **Owner** column shows the AWS account ID of the account that launched the instance.

Command line

To view the instances running on a shared Dedicated Host using the AWS CLI

Use the [describe-hosts](#) command. The command returns the instances running on each Dedicated Host. Owners see all of the instances running on the host. Consumers only see running instances that they launched on the shared hosts. InstanceOwnerId shows the AWS account ID of the instance owner.

Shared Dedicated Host permissions

Permissions for owners

Owners are responsible for managing their shared Dedicated Hosts and the instances that they launch onto them. Owners can view all instances running on the shared Dedicated Host, including those launched by consumers. However, owners can't take any action on running instances that were launched by consumers.

Permissions for consumers

Consumers are responsible for managing the instances that they launch onto a shared Dedicated Host. Consumers can't modify the shared Dedicated Host in any way, and they can't view or modify instances that were launched by other consumers or the Dedicated Host owner.

Billing and metering

There are no additional charges for sharing Dedicated Hosts.

Owners are billed for Dedicated Hosts that they share. Consumers are not billed for instances that they launch onto shared Dedicated Hosts.

Dedicated Host Reservations continue to provide billing discounts for shared Dedicated Hosts. Only Dedicated Host owners can purchase Dedicated Host Reservations for shared Dedicated Hosts that they own.

Dedicated Host limits

Shared Dedicated Hosts count towards the owner's Dedicated Hosts limits only. Consumer's Dedicated Hosts limits are not affected by Dedicated Hosts that have been shared with them. Similarly, instances that consumers launch onto shared Dedicated Hosts do not count towards their instance limits.

Host recovery and Dedicated Host sharing

Host recovery recovers instances launched by the Dedicated Host owner and the consumers with whom it has been shared. The replacement Dedicated Host is allocated to the owner's account. It is added to the same resource shares as the original Dedicated Host, and it is shared with the same consumers.

For more information, see [Host recovery \(p. 488\)](#).

Dedicated Hosts on AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to your premises. By providing local access to AWS managed infrastructure, AWS Outposts enables you to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region.

You can allocate Dedicated Hosts on Outposts that you own in your account. This makes it easier for you to bring your existing software licenses and workloads that require a dedicated physical server to AWS Outposts. You can also target specific hardware assets on an Outpost to help minimize latency between your workloads.

Dedicated Hosts allow you to use your eligible software licenses on Amazon EC2, so that you get the flexibility and cost effectiveness of using your own licenses. Other software licenses that are bound to virtual machines, sockets, or physical cores, can also be used on Dedicated Hosts, subject to their license terms. While Outposts have always been a single-tenant environments that are eligible for BYOL workloads, Dedicated Hosts allows you to limit the needed licenses to a single host as opposed to the entire Outpost deployment.

Additionally, using Dedicated Hosts on an Outpost gives you greater flexibility in instance type deployment, and more granular control over instance placement. You can target a specific host for instance launches and use host affinity to ensure that the instance always runs on that host, or you can use auto-placement to launch an instance onto any available host that has matching configurations and available capacity.

Contents

- [Prerequisites \(p. 487\)](#)
- [Supported features \(p. 487\)](#)
- [Considerations \(p. 487\)](#)
- [Allocate and use a Dedicated Host on an Outpost \(p. 487\)](#)

Prerequisites

You must have an Outpost installed at your site. For more information, see [Create an Outpost and order Outpost capacity](#) in the *AWS Outposts User Guide*.

Supported features

- The following instance families are supported: C5, M5, R5, C5d, M5d, R5d, G4dn, and i3en.
- Dedicated Hosts on Outposts can be configured to support multiple instance sizes. Support for multiple instance sizes is available for the following instance families: C5, M5, R5, C5d, M5d, and R5d. For more information, see [Instance capacity configurations \(p. 458\)](#).
- Dedicated Hosts on Outposts support auto-placement and targeted instance launches. For more information, see [Understand auto-placement and affinity \(p. 470\)](#).
- Dedicated Hosts on Outposts support host affinity. For more information, see [Understand auto-placement and affinity \(p. 470\)](#).
- Dedicated Hosts on Outposts support sharing with AWS RAM. For more information, see [Work with shared Dedicated Hosts \(p. 481\)](#).

Considerations

- Dedicated Host Reservations are not supported on Outposts.
- Host resource groups and AWS License Manager are not supported on Outposts.
- Dedicated Hosts on Outposts do not support burstable T3 instances.
- Dedicated Hosts on Outposts do not support host recovery.

Allocate and use a Dedicated Host on an Outpost

You allocate and use Dedicated Hosts on Outposts in the same way that would with Dedicated Hosts in an AWS Region.

Prerequisites

Create a subnet on the Outpost. For more information, see [Create a subnet](#) in the *AWS Outposts User Guide*.

To allocate a Dedicated Host on an Outpost, use one of the following methods:

AWS Outposts console

1. Open the AWS Outposts console at <https://console.aws.amazon.com/outposts/>.
2. In the navigation pane, choose **Outposts**. Select the Outpost and then choose **Actions**, **Allocate Dedicated Host**.
3. Configure the Dedicated Host as needed. For more information, see [Allocate Dedicated Hosts \(p. 464\)](#).

Note

Availability Zone and **Outpost ARN** should be pre-populated with the Availability Zone and ARN of the selected Outpost.

4. Choose **Allocate**.

Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**, and then choose **Allocate Dedicated Host**.
3. For **Availability Zone**, select the Availability Zone associated with the Outpost.
4. For **Outpost ARN**, enter the ARN of the Outpost.
5. To target specific hardware assets on the Outpost, for **Target specific hardware assets on Outpost**, select **Enable**. For each hardware asset to target, choose **Add asset ID**, and then enter the ID of the hardware asset.

Note

The value that you specify for **Quantity** must be equal to the number of asset IDs that you specify. For example, if you specify 3 asset IDs, then Quantity must also be 3.

6. Configure the remaining Dedicated Host settings as needed. For more information, see [Allocate Dedicated Hosts \(p. 464\)](#).
7. Choose **Allocate**.

AWS CLI

Use the [allocate-hosts](#) AWS CLI command. For `--availability-zone`, specify the Availability Zone associated with the Outpost. For `--outpost-arn`, specify the ARN of the Outpost. Optionally, for `--asset-ids`, specify the IDs of the Outpost hardware assets to target.

```
aws ec2 allocate-hosts --availability-zone "us-east-1a" --outpost-arn
  "arn:aws:outposts:us-east-1a:11122223333:outpost/op-4fe3dc21baEXAMPLE" --asset-
  ids asset_id --instance-family "m5" --auto-placement "off" --quantity 1
```

To launch an instance onto a Dedicated Host on an Outpost

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**. Select the Dedicated Host that you allocated in the previous step and choose **Actions, Launch instance onto host**.
3. Configure the instance as needed and then launch the instance. For more information, see [Launch instances onto a Dedicated Host \(p. 467\)](#).

Host recovery

Dedicated Host auto recovery restarts your instances on to a new replacement host when certain problematic conditions are detected on your Dedicated Host. Host recovery reduces the need for manual intervention and lowers the operational burden if there is an unexpected Dedicated Host failure concerning system power or network connectivity events. Other Dedicated Host issues will require manual intervention to recover from.

Contents

- [Host recovery basics \(p. 489\)](#)
- [Supported instance types \(p. 490\)](#)
- [Configure host recovery \(p. 490\)](#)
- [Host recovery states \(p. 492\)](#)

- [Manually recover unsupported instances \(p. 492\)](#)
- [Related services \(p. 492\)](#)
- [Pricing \(p. 493\)](#)

Host recovery basics

Dedicated Hosts and the host resource groups recovery process use host-level health checks to assess Dedicated Host availability and to detect underlying system failures. The type of Dedicated Host failure determines if Dedicated Host auto recovery is possible. Examples of problems that can cause host-level health checks to fail include:

- Loss of network connectivity
- Loss of system power
- Hardware or software issues on the physical host

Important

Dedicated Host auto recovery does not occur when the host is scheduled for retirement.

Dedicated Host auto recovery

When a system power or network connectivity failure is detected on your Dedicated Host, Dedicated Host auto recovery is initiated and Amazon EC2 **automatically allocates a replacement Dedicated Host**. The replacement Dedicated Host receives a new host ID, but retains the same attributes as the original Dedicated Host, including:

- Availability Zone
- Instance type
- Tags
- Auto placement settings
- Reservation

When the replacement Dedicated Host is allocated, the **instances are recovered on to the replacement Dedicated Host**. The recovered instances retain the same attributes as the original instances, including:

- Instance ID
- Private IP addresses
- Elastic IP addresses
- EBS volume attachments
- All instance metadata

Additionally, the built-in integration with AWS License Manager automates the tracking and management of your licenses.

Note

AWS License Manager integration is supported only in Regions in which AWS License Manager is available.

If instances have a host affinity relationship with the impaired Dedicated Host, the recovered instances establish host affinity with the replacement Dedicated Host.

When all of the instances have been recovered on to the replacement Dedicated Host, **the impaired Dedicated Host is released**, and the replacement Dedicated Host becomes available for use.

When host recovery is initiated, the AWS account owner is notified by email and by an AWS Health Dashboard event. A second notification is sent after the host recovery has been successfully completed.

If you are using AWS License Manager to track your licenses, AWS License Manager allocates new licenses for the replacement Dedicated Host based on the license configuration limits. If the license configuration has hard limits that will be breached as a result of the host recovery, the recovery process is not allowed and you are notified of the host recovery failure through an Amazon SNS notification (if notification settings have been configured for AWS License Manager). If the license configuration has soft limits that will be breached as a result of the host recovery, the recovery is allowed to continue and you are notified of the limit breach through an Amazon SNS notification. For more information, see [Using License Configurations](#) and [Settings in License Manager](#) in the *AWS License Manager User Guide*.

Scenarios without Dedicated Host auto recovery

Dedicated Host auto recovery does not occur when the host is scheduled for retirement. You will receive a retirement notification in the AWS Health Dashboard, an Amazon CloudWatch event, and the AWS account owner email address receives a message regarding the Dedicated Host failure. Follow the remedial steps described in the retirement notification within the specified time period to manually recover the instances on the retiring host.

Stopped instances are not recovered on to the replacement Dedicated Host. If you attempt to start a stopped instance that targets the impaired Dedicated Host, the instance start fails. We recommend that you modify the stopped instance to either target a different Dedicated Host, or to launch on any available Dedicated Host with matching configurations and auto-placement enabled.

Instances with instance storage are not recovered on to the replacement Dedicated Host. As a remedial measure, the impaired Dedicated Host is marked for retirement and you receive a retirement notification after the host recovery is complete. Follow the remedial steps described in the retirement notification within the specified time period to manually recover the remaining instances on the impaired Dedicated Host.

Supported instance types

Host recovery is supported for the following instance families: A1, C3, C4, C5, C5n, C6a, C6g, C6i, Inf1, G2, G3, G5g, M3, M4, M5, M5n, M5zn, M6a, M6g, M6i, P2, P3, R3, R4, R5, R5b, R5n, R6g, R6i, T3, X1, X1e, X2iezn, u-6tb1, u-9tb1, u-12tb1, u-18tb1, and u-24tb1.

To recover instances that are not supported, see [Manually recover unsupported instances \(p. 492\)](#).

Note

Dedicated Host auto recovery of supported metal [instance types](#) will take longer to detect and recover from than non-metal instance types.

Configure host recovery

You can configure host recovery at the time of Dedicated Host allocation, or after allocation using the Amazon EC2 console or AWS Command Line Interface (CLI).

Contents

- [Enable host recovery \(p. 490\)](#)
- [Disable host recovery \(p. 491\)](#)
- [View the host recovery configuration \(p. 491\)](#)

Enable host recovery

You can enable host recovery at the time of Dedicated Host allocation or after allocation.

For more information about enabling host recovery at the time of Dedicated Host allocation, see [Allocate Dedicated Hosts \(p. 464\)](#).

To enable host recovery after allocation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host for which to enable host recovery, and then choose **Actions, Modify Host Recovery**.
4. For **Host recovery**, choose **Enable**, and then choose **Save**.

To enable host recovery after allocation using the AWS CLI

Use the [modify-hosts](#) command and specify the `host-recovery` parameter.

```
$ aws ec2 modify-hosts --host-recovery on --host-ids h-012a3456b7890cdef
```

Disable host recovery

You can disable host recovery at any time after the Dedicated Host has been allocated.

To disable host recovery after allocation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host for which to disable host recovery, and then choose **Actions, Modify Host Recovery**.
4. For **Host recovery**, choose **Disable**, and then choose **Save**.

To disable host recovery after allocation using the AWS CLI

Use the [modify-hosts](#) command and specify the `host-recovery` parameter.

```
$ aws ec2 modify-hosts --host-recovery off --host-ids h-012a3456b7890cdef
```

View the host recovery configuration

You can view the host recovery configuration for a Dedicated Host at any time.

To view the host recovery configuration for a Dedicated Host using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host, and in the **Description** tab, review the **Host Recovery** field.

To view the host recovery configuration for a Dedicated Host using the AWS CLI

Use the [describe-hosts](#) command.

```
$ aws ec2 describe-hosts --host-ids h-012a3456b7890cdef
```

The HostRecovery response element indicates whether host recovery is enabled or disabled.

Host recovery states

When a Dedicated Host failure is detected, the impaired Dedicated Host enters the under-assessment state, and all of the instances enter the impaired state. You can't launch instances on to the impaired Dedicated Host while it is in the under-assessment state.

After the replacement Dedicated Host is allocated, it enters the pending state. It remains in this state until the host recovery process is complete. You can't launch instances on to the replacement Dedicated Host while it is in the pending state. Recovered instances on the replacement Dedicated Host remain in the impaired state during the recovery process.

After the host recovery is complete, the replacement Dedicated Host enters the available state, and the recovered instances return to the running state. You can launch instances on to the replacement Dedicated Host after it enters the available state. The original impaired Dedicated Host is permanently released and it enters the released-permanent-failure state.

If the impaired Dedicated Host has instances that do not support host recovery, such as instances with instance store-backed volumes, the Dedicated Host is not released. Instead, it is marked for retirement and enters the permanent-failure state.

Manually recover unsupported instances

Host recovery does not support recovering instances that use instance store volumes. Follow the instructions below to manually recover any of your instances that could not be automatically recovered.

Warning

Data on instance store volumes is lost when an instance is stopped, hibernated, or terminated. This includes instance store volumes that are attached to an instance that has an EBS volume as the root device. To protect data from instance store volumes, back it up to persistent storage before the instance is stopped or terminated.

Manually recover EBS-backed instances

For EBS-backed instances that could not be automatically recovered, we recommend that you manually stop and start the instances to recover them onto a new Dedicated Host. For more information about stopping your instance, and about the changes that occur in your instance configuration when it's stopped, see [Stop and start your instance \(p. 594\)](#).

Manually recover instance store-backed instances

For instance store-backed instances that could not be automatically recovered, we recommend that you do the following:

1. Launch a replacement instance on a new Dedicated Host from your most recent AMI.
2. Migrate all of the necessary data to the replacement instance.
3. Terminate the original instance on the impaired Dedicated Host.

Related services

Dedicated Host integrates with the following services:

- **AWS License Manager**—Tracks licenses across your Amazon EC2 Dedicated Hosts (supported only in Regions in which AWS License Manager is available). For more information, see the [AWS License Manager User Guide](#).

Pricing

There are no additional charges for using host recovery, but the usual Dedicated Host charges apply. For more information, see [Amazon EC2 Dedicated Hosts Pricing](#).

As soon as host recovery is initiated, you are no longer billed for the impaired Dedicated Host. Billing for the replacement Dedicated Host begins only after it enters the available state.

If the impaired Dedicated Host was billed using the On-Demand rate, the replacement Dedicated Host is also billed using the On-Demand rate. If the impaired Dedicated Host had an active Dedicated Host Reservation, it is transferred to the replacement Dedicated Host.

Host maintenance

With host maintenance, your Amazon EC2 instances on a degraded Dedicated Host are automatically rebooted on a newly allocated Dedicated Host during a scheduled maintenance event. This helps reduce application downtime and offloads the undifferentiated heavy-lift of maintenance to AWS. Host maintenance is also performed for planned and routine Amazon EC2 maintenance.

Host maintenance is supported on all new Dedicated Host allocations made through Amazon EC2 console. For any Dedicated Host in your AWS account or any new Dedicated Host allocated through [AllocateHosts API](#), you can configure host maintenance for supported Dedicated Hosts. For more information, see [the section called "Configuring host maintenance" \(p. 495\)](#).

Contents

- [Host maintenance basics \(p. 493\)](#)
- [Host maintenance versus host recovery \(p. 494\)](#)
- [Supported instance types \(p. 494\)](#)
- [Instances on Dedicated Host \(p. 494\)](#)
- [Configuring host maintenance \(p. 495\)](#)
- [Maintenance event \(p. 496\)](#)
- [Host maintenance states \(p. 497\)](#)
- [Related services \(p. 497\)](#)
- [Pricing \(p. 497\)](#)

Host maintenance basics

When degradation is detected on a Dedicated Host, a new Dedicated Host is allocated. Degradation can be caused by degradation of the underlying hardware or detection of certain problematic conditions. Your instances on the degraded Dedicated Host are scheduled to be automatically rebooted on the newly allocated Dedicated Host.

The replacement Dedicated Host receives a new host ID, but retains the same attributes as the original Dedicated Host. These attributes include the following.

- Auto placement settings
- Availability Zone
- Reservation
- Host affinity
- Host maintenance settings
- Host recovery settings
- Instance type

- Tags

Host maintenance is available in all AWS Regions for all supported Dedicated Hosts. For more information about Dedicated Hosts where host maintenance is not supported, see [the section called "Limitations" \(p. 494\)](#).

Your degraded Dedicated Host is released after all of your instances have been rebooted to a new Dedicated Host or stopped. You can access your instances on the degraded Dedicated Host before the scheduled maintenance event, but launching instances on the degraded Dedicated Host is not supported.

You can use the newly allocated Dedicated Host to launch new instances on the host before the scheduled maintenance event. Some capacity on the new host is reserved for rebooting instances from the degraded host. For more information, see [the section called "Instances on Dedicated Host" \(p. 494\)](#).

Limitations

- Host maintenance is not supported in AWS Outposts, AWS Local Zones, and AWS Wavelength Zones.
- Host maintenance cannot be turned on or off for hosts already within a host resource group. Hosts added to a host resource group retain their host maintenance setting. For more information, see [Host resource groups](#).
- Host maintenance is only supported on specific instance types. For more information, see [the section called "Supported instance types" \(p. 494\)](#).

Host maintenance versus host recovery

The following table shows the main differences between host recovery and host maintenance.

	Host recovery	Host maintenance
Accessibility	Unreachable	Reachable
State	under-assessment	permanent-failure
Action	Recovery is immediate	Maintenance is scheduled
Scheduling flexibility	Cannot be rescheduled	Can be rescheduled
Host Resource Group	Supported	Not supported

For more information about host recovery, see [Host recovery](#).

Supported instance types

Host maintenance is supported for the following instance families: A1, C4, C5, C5n, C6a, C6g, C6i, Inf1, G3, G5g, M4, M5, M5n, M5zn, M6a, M6g, M6i, P2, P3, R4, R5, R5b, R5n, R6g, R6i, T3, u-6tb1, u-9tb1, u-12tb1, u-18tb1, u-24tb1, and X2iezn.

Instances on Dedicated Host

During the scheduled maintenance event, the instances on your degraded host are rebooted on a newly allocated Dedicated Host. The instances retain the same attributes as the ones on your degraded host, including the following.

- Amazon EBS volume attachments
- Elastic IP addresses

- Instance ID
- Instance metadata
- Private IP address

You can **stop and start an instance** on the degraded host at any point before the scheduled maintenance event is initiated. Doing this reboots your instance on to another host, and your instance won't undergo scheduled maintenance. You must update your instance's host affinity to the new host where you want to reboot your instance. For more information, see [Stop and start your instance](#).

Note

The data on any local store volume is not preserved when you stop and start your instance.

Instances with an **instance store volume** as the root device are terminated after the specified termination date. Any data on the instance store volumes is deleted when the instances are terminated. Terminated instances are permanently deleted, and cannot be started again. For instances with instance store volumes as the root device, we recommend launching replacement instances on a different Dedicated Host using the most recent Amazon Machine Image, and migrating all available data to the replacement instances before the specified termination date. For more information, see [Instance retirement](#).

Instances that **cannot be rebooted** automatically are stopped after the specified date. You can start these instances again on a different host. Instances using an Amazon EBS volume as a root device continue to use the same Amazon EBS volume after being started on a new host.

You can set the **order of instance reboot** by rescheduling the start time of an instance reboot in <https://console.aws.amazon.com/ec2/>.

Configuring host maintenance

You can configure host maintenance for all supported Dedicated Hosts via AWS Management Console or AWS CLI. See the following table for more details.

AWS Management Console

To enable host maintenance for your Dedicated Host using AWS Management Console.

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host > **Actions** > **Modify host**.
4. Select **on** in the **Host maintenance** field.

To disable host maintenance for your Dedicated Host using AWS Management Console.

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host > **Actions** > **Modify host**.
4. Select **off** in the **Host maintenance** field.

To view the host maintenance configuration for your Dedicated Host using AWS Management Console.

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host, and in the **Description** tab, review the **Host maintenance** field.

AWS CLI

To enable or disable host maintenance for your new Dedicated Host during allocation using AWS CLI.

Use the [allocate-hosts](#) command.

Enable

```
aws ec2 allocate-hosts --region us-east-1 --quantity 1 --instance-type m3.large --availability-zone us-east-1b --host-maintenance on
```

Disable

```
aws ec2 allocate-hosts --region us-east-1 --quantity 1 --instance-type m3.large --availability-zone us-east-1b --host-maintenance off
```

To enable or disable host maintenance for your existing Dedicated Host using AWS CLI.

Use the [modify-hosts](#) command.

Enable

```
aws ec2 modify-hosts --region us-east-1 --host-maintenance on --host-ids h-0d123456bbf78910d
```

Disable

```
aws ec2 modify-hosts --region us-east-1 --host-maintenance off --host-ids h-0d123456bbf78910d
```

To view the host maintenance configuration for your Dedicated Host using AWS CLI.

Use the [describe-hosts](#) command.

```
aws ec2 describe-hosts --region us-east-1 --host-ids h-0d123456bbf78910d
```

Note

If you disable host maintenance, you receive an email notification to evict the degraded host and manually migrate your instances to another host within 28 days. A replacement host is allocated if you have Dedicated Host reservation. After 28 days, the instances running on the degraded host are terminated, and the host is released automatically.

Maintenance event

On detection of degradation, a maintenance event is scheduled 14 days later, to reboot your instances on a new Dedicated Host. You receive an email notification providing details about the degraded host, scheduled maintenance event, and maintenance time slots. For more information, see [View scheduled events](#).

You can reschedule the maintenance event for any day up to seven days after the date of the scheduled event. For more information about rescheduling, see [Reschedule a scheduled event](#).

The maintenance event usually takes a few minutes to complete. In the rare case of unsuccessful event, you receive an email notification to evict the instances on the degraded host within a specified time frame.

Host maintenance states

Your Dedicated Host is set to permanent-failure state when degradation is detected. You cannot launch instances on a Dedicated Host in the state of permanent-failure. On completion of maintenance event, the degraded host is released and put in the state of released, permanent-failure.

After detecting degradation on a Dedicated Host and before scheduling a maintenance event, host maintenance automatically allocates a new Dedicated Host in your account. This newly allocated replacement host stays in a pending state until a maintenance event is scheduled. Once the maintenance event is scheduled, the new Dedicated Host moves to the available state. You can launch new instances on this host at any time, even before the maintenance event.

Note

The capacity required to migrate existing instances from the degraded host to the new host is made unavailable to enable a smooth transition during the maintenance event.

Related services

Dedicated Host integrates with **AWS License Manager**—Tracks licenses across your Amazon EC2 Dedicated Hosts (supported only in Regions in which AWS License Manager is available). For more information, see the [AWS License Manager User Guide](#).

You must have sufficient licenses in your AWS account for your new Dedicated Host. The licenses associated with your degraded host are released when the host is released after the completion of the scheduled maintenance event.

Pricing

There are no additional charges for using host maintenance, but the usual Dedicated Host charges apply. For more information, see [Amazon EC2 Dedicated Hosts Pricing](#).

As soon as host maintenance is initiated, you are no longer billed for the degraded Dedicated Host. Billing for the newly allocated Dedicated Host begins only after it enters the available state.

If the degraded Dedicated Host was billed using the On-Demand rate, the newly allocated Dedicated Host is also billed using the On-Demand rate. If the degraded Dedicated Host had an active Dedicated Host Reservation, it is transferred to the new Dedicated Host.

Track configuration changes

You can use AWS Config to record configuration changes for Dedicated Hosts, and for instances that are launched, stopped, or terminated on them. You can then use the information captured by AWS Config as a data source for license reporting.

AWS Config records configuration information for Dedicated Hosts and instances individually, and pairs this information through relationships. There are three reporting conditions:

- **AWS Config recording status**—When **On**, AWS Config is recording one or more AWS resource types, which can include Dedicated Hosts and Dedicated Instances. To capture the information required for license reporting, verify that hosts and instances are being recorded with the following fields.
 - **Host recording status**—When **Enabled**, the configuration information for Dedicated Hosts is recorded.
 - **Instance recording status**—When **Enabled**, the configuration information for Dedicated Instances is recorded.

If any of these three conditions are disabled, the icon in the **Edit Config Recording** button is red. To derive the full benefit of this tool, ensure that all three recording methods are enabled. When all three

are enabled, the icon is green. To edit the settings, choose **Edit Config Recording**. You are directed to the **Set up AWS Config** page in the AWS Config console, where you can set up AWS Config and start recording for your hosts, instances, and other supported resource types. For more information, see [Setting up AWS Config using the Console](#) in the *AWS Config Developer Guide*.

Note

AWS Config records your resources after it discovers them, which might take several minutes.

After AWS Config starts recording configuration changes to your hosts and instances, you can get the configuration history of any host that you have allocated or released and any instance that you have launched, stopped, or terminated. For example, at any point in the configuration history of a Dedicated Host, you can look up how many instances are launched on that host, along with the number of sockets and cores on the host. For any of those instances, you can also look up the ID of its Amazon Machine Image (AMI). You can use this information to report on licensing for your own server-bound software that is licensed per-socket or per-core.

You can view configuration histories in any of the following ways:

- By using the AWS Config console. For each recorded resource, you can view a timeline page, which provides a history of configuration details. To view this page, choose the gray icon in the **Config Timeline** column of the **Dedicated Hosts** page. For more information, see [Viewing Configuration Details in the AWS Config Console](#) in the *AWS Config Developer Guide*.
- By running AWS CLI commands. First, you can use the [list-discovered-resources](#) command to get a list of all hosts and instances. Then, you can use the [get-resource-config-history](#) command to get the configuration details of a host or instance for a specific time interval. For more information, see [View Configuration Details Using the CLI](#) in the *AWS Config Developer Guide*.
- By using the AWS Config API in your applications. First, you can use the [ListDiscoveredResources](#) action to get a list of all hosts and instances. Then, you can use the [GetResourceConfigHistory](#) action to get the configuration details of a host or instance for a specific time interval.

For example, to get a list of all of your Dedicated Hosts from AWS Config, run a CLI command such as the following.

```
aws configservice list-discovered-resources --resource-type AWS::EC2::Host
```

To obtain the configuration history of a Dedicated Host from AWS Config, run a CLI command such as the following.

```
aws configservice get-resource-config-history --resource-type AWS::EC2::Instance --  
resource-id i-1234567890abcdef0
```

To manage AWS Config settings using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the **Dedicated Hosts** page, choose **Edit Config Recording**.
3. In the AWS Config console, follow the steps provided to turn on recording. For more information, see [Setting up AWS Config using the Console](#).

For more information, see [Viewing Configuration Details in the AWS Config Console](#).

To activate AWS Config using the command line or API

- AWS CLI: [Viewing Configuration Details \(AWS CLI\)](#) in the *AWS Config Developer Guide*.
- Amazon EC2 API: [GetResourceConfigHistory](#).

Dedicated Instances

By default, EC2 instances run on shared tenancy hardware. Dedicated Instances are EC2 instances that run on hardware that's dedicated to a single customer. Dedicated Instances that belong to different AWS accounts are physically isolated at a hardware level, even if those accounts are linked to a single payer account. However, Dedicated Instances might share hardware with other instances from the same AWS account that are not Dedicated Instances.

A *Dedicated Host* is also a physical server that's dedicated for your use. With a Dedicated Host, you have visibility and control over how instances are placed on the server. For more information, see [Dedicated Hosts \(p. 458\)](#).

Topics

- [Dedicated Instance basics \(p. 499\)](#)
- [Supported features \(p. 499\)](#)
- [Differences between Dedicated Instances and Dedicated Hosts \(p. 500\)](#)
- [Dedicated Instances limitations \(p. 501\)](#)
- [Pricing for Dedicated Instances \(p. 501\)](#)
- [Work with Dedicated Instances \(p. 501\)](#)

Dedicated Instance basics

A VPC can have a tenancy of either `default` or `dedicated`. By default, your VPCs have `default` tenancy and instances launched into a `default` tenancy VPC have `default` tenancy. To launch Dedicated Instances, do the following:

- Create a VPC with a tenancy of `dedicated`, so that all instances in the VPC run as Dedicated Instances. For more information, see [Create a VPC with a dedicated instance tenancy \(p. 502\)](#).
- Create a VPC with a tenancy of `default` and manually specify a tenancy of `dedicated` for the instances to run as Dedicated Instances. For more information, see [Launch Dedicated Instances into a VPC \(p. 502\)](#).

Supported features

Dedicated Instances support the following features and AWS service integrations:

Topics

- [Reserved Instances \(p. 499\)](#)
- [Automatic scaling \(p. 500\)](#)
- [Automatic recovery \(p. 500\)](#)
- [Dedicated Spot Instances \(p. 500\)](#)
- [Burstable performance instances \(p. 500\)](#)

Reserved Instances

To guarantee that sufficient capacity is available to launch Dedicated Instances, you can purchase Dedicated Reserved Instances or Capacity Reservations. For more information, see [Reserved Instances \(p. 353\)](#) and [On-Demand Capacity Reservations \(p. 504\)](#).

When you purchase a Dedicated Reserved Instance, you are purchasing the capacity to launch a Dedicated Instance into a VPC at a much reduced usage fee; the price break in the usage charge applies

only if you launch an instance with dedicated tenancy. When you purchase a Reserved Instance with default tenancy, it applies only to a running instance with default tenancy; it does not apply to a running instance with dedicated tenancy.

You can't use the modification process to change the tenancy of a Reserved Instance after you've purchased it. However, you can exchange a Convertible Reserved Instance for a new Convertible Reserved Instance with a different tenancy.

Automatic scaling

You can use Amazon EC2 Auto Scaling to launch Dedicated Instances. For more information, see [Launching Auto Scaling Instances in a VPC](#) in the *Amazon EC2 Auto Scaling User Guide*.

Automatic recovery

You can configure automatic recovery for a Dedicated Instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. For more information, see [Recover your instance \(p. 622\)](#).

Dedicated Spot Instances

You can run a Dedicated Spot Instance by specifying a tenancy of dedicated when you create a Spot Instance request. For more information, see [Specify a tenancy for your Spot Instances \(p. 406\)](#).

Burstable performance instances

You can leverage the benefits of running on dedicated tenancy hardware with [the section called "Burstable performance instances" \(p. 245\)](#). T3 Dedicated Instances launch in unlimited mode by default, and they provide a baseline level of CPU performance with the ability to burst to a higher CPU level when required by your workload. The T3 baseline performance and ability to burst are governed by CPU credits. Because of the burstable nature of the T3 instance types, we recommend that you monitor how your T3 instances use the CPU resources of the dedicated hardware for the best performance. T3 Dedicated Instances are intended for customers with diverse workloads that display random CPU behavior, but that ideally have average CPU usage at or below the baseline usages. For more information, see [the section called "Key concepts" \(p. 247\)](#).

Amazon EC2 has systems in place to identify and correct variability in performance. However, it is still possible to experience short-term variability if you launch multiple T3 Dedicated Instances that have correlated CPU usage patterns. For these more demanding or correlated workloads, we recommend using M5 or M5a Dedicated Instances rather than T3 Dedicated Instances.

Differences between Dedicated Instances and Dedicated Hosts

Dedicated Instances and Dedicated Hosts can both be used to launch Amazon EC2 instances onto physical servers that are dedicated for your use.

There are no performance, security, or physical differences between Dedicated Instances and instances on Dedicated Hosts. However, there are some differences between the two. The following table highlights some of the key differences between Dedicated Instances and Dedicated Hosts:

	Dedicated Host	Dedicated Instance
Billing	Per-host billing	Per-instance billing
Visibility of sockets, cores, and host ID	Provides visibility of the number of sockets and physical cores	No visibility

	Dedicated Host	Dedicated Instance
Host and instance affinity	Allows you to consistently deploy your instances to the same physical server over time	Not supported
Targeted instance placement	Provides additional visibility and control over how instances are placed on a physical server	Not supported
Automatic instance recovery	Supported. For more information, see Host recovery (p. 488) .	Supported
Bring Your Own License (BYOL)	Supported	Partial support *
Capacity Reservations	Not supported	Supported

* Microsoft SQL Server with License Mobility through Software Assurance, and Windows Virtual Desktop Access (VDA) licenses can be used with Dedicated Instance.

For more information about Dedicated Hosts, see [Dedicated Hosts \(p. 458\)](#).

Dedicated Instances limitations

Keep the following in mind when using Dedicated Instances:

- Some AWS services or their features are not supported with a VPC with the instance tenancy set to dedicated. Refer to the respective service's documentation to confirm if there are any limitations.
- Some instance types can't be launched into a VPC with the instance tenancy set to dedicated. For more information about supported instance types, see [Amazon EC2 Dedicated Instances](#).
- When you launch a Dedicated Instance backed by Amazon EBS, the EBS volume doesn't run on single-tenant hardware.

Pricing for Dedicated Instances

Pricing for Dedicated Instances is different from pricing for On-Demand Instances. For more information, see the [Amazon EC2 Dedicated Instances product page](#).

Work with Dedicated Instances

You can create a VPC with an instance tenancy of dedicated to ensure that all instances launched into the VPC are Dedicated Instances. Alternatively, you can specify the tenancy of the instance during launch.

Topics

- [Create a VPC with a dedicated instance tenancy \(p. 502\)](#)
- [Launch Dedicated Instances into a VPC \(p. 502\)](#)
- [Display tenancy information \(p. 502\)](#)
- [Change the tenancy of an instance \(p. 503\)](#)
- [Change the tenancy of a VPC \(p. 504\)](#)

Create a VPC with a dedicated instance tenancy

When you create a VPC, you have the option of specifying its instance tenancy. If you launch an instance into a VPC that has an instance tenancy of dedicated, your instance is automatically a Dedicated Instance, regardless of the tenancy of the instance.

For more information about creating a VPC and choosing the tenancy options, see [Create a VPC](#) in the *Amazon VPC User Guide*.

Launch Dedicated Instances into a VPC

You can launch a Dedicated Instance using the Amazon EC2 launch instance wizard.

Console

To launch a Dedicated Instance into a default tenancy VPC using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, **Launch instance**.
3. In the **Application and OS Images** section, select an AMI from the list.
4. In the **Instance type** section, select the instance type to launch.

Note

Ensure that you choose an instance type that's supported as a Dedicated Instance. For more information, see [Amazon EC2 Dedicated Instances](#).

5. In the **Key pair** section, select the key pair to associate with the instance.
6. In the **Advanced details** section, for **Tenancy**, select **Dedicated**.
7. Configure the remaining instance options as needed. For more information, see [Launch an instance using defined parameters \(p. 554\)](#).
8. Choose **Launch instance**.

Command line

To set the tenancy option for an instance during launch using the command line

- [run-instances](#) (AWS CLI)
- [New-EC2Instance](#) (AWS Tools for Windows PowerShell)

For more information about launching an instance with a tenancy of host, see [Launch instances onto a Dedicated Host \(p. 467\)](#).

Display tenancy information

Console

To display tenancy information for your VPC using the console

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the navigation pane, choose **Your VPCs**.
3. Check the instance tenancy of your VPC in the **Tenancy** column.
4. If the **Tenancy** column is not displayed, choose the settings icon () in the top-right corner, toggle to choose **Tenancy**, and choose **Confirm**.

To display tenancy information for your instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Check the tenancy of your instance in the **Tenancy** column.
4. If the **Tenancy** column is not displayed, do one of the following:
 - Choose the settings icon () in the top-right corner, toggle to choose **Tenancy**, and choose **Confirm**.
 - Select the instance. On the **Details** tab near the bottom of the page, under **Host and placement group**, check the value for **Tenancy**.

Command line

To describe the tenancy of your VPC using the command line

- [describe-vpcs](#) (AWS CLI)
- [Get-EC2Vpc](#) (AWS Tools for Windows PowerShell)

To describe the tenancy of your instance using the command line

- [describe-instances](#) (AWS CLI)
- [Get-EC2Instance](#) (AWS Tools for Windows PowerShell)

To describe the tenancy value of a Reserved Instance using the command line

- [describe-reserved-instances](#) (AWS CLI)
- [Get-EC2ReservedInstance](#) (AWS Tools for Windows PowerShell)

To describe the tenancy value of a Reserved Instance offering using the command line

- [describe-reserved-instances-offerings](#) (AWS CLI)
- [Get-EC2ReservedInstancesOffering](#) (AWS Tools for Windows PowerShell)

Change the tenancy of an instance

You can change the tenancy of a stopped instance after launch. The changes that you make take effect the next time the instance starts.

Note

For T3 instances, you can't change the tenancy from dedicated to host, or from host to dedicated. Attempting to make one of these unsupported tenancy changes results in the `InvalidTenancy` error code.

Console

To change the tenancy of an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select your instance.
3. Choose **Instance state**, **Stop instance**, **Stop**.
4. Choose **Actions**, **Instance settings**, **Modify instance placement**.

5. For **Tenancy**, choose whether to run your instance on dedicated hardware or on a Dedicated Host. Choose **Save**.

Command line

To modify the tenancy value of an instance using the command line

- [modify-instance-placement](#) (AWS CLI)
- [Edit-EC2InstancePlacement](#) (AWS Tools for Windows PowerShell)

Change the tenancy of a VPC

You can change the instance tenancy of a VPC from dedicated to default after you create it. Modifying the instance tenancy of the VPC does not affect the tenancy of any existing instances in the VPC. The next time you launch an instance in the VPC, it has a tenancy of default, unless you specify otherwise during launch.

Note

You cannot change the instance tenancy of a VPC from default to dedicated after it is created.

You can modify the instance tenancy of a VPC using the AWS CLI, an AWS SDK, or the Amazon EC2 API only.

Command line

To modify the instance tenancy attribute of a VPC using the AWS CLI

Use the [modify-vpc-tenancy](#) command and specify the ID of the VPC and instance tenancy value. The only supported value is default.

```
aws ec2 modify-vpc-tenancy --vpc-id vpc-1a2b3c4d --instance-tenancy default
```

On-Demand Capacity Reservations

On-Demand Capacity Reservations enable you to reserve compute capacity for your Amazon EC2 instances in a specific Availability Zone for any duration. Capacity Reservations mitigate against the risk of being unable to get On-Demand capacity in case there are capacity constraints. If you have strict capacity requirements, and are running business-critical workloads that require a certain level of long or short-term capacity assurance, we recommend that you create a Capacity Reservation to ensure that you always have access to Amazon EC2 capacity when you need it, for as long as you need it.

The following are some common use cases for Capacity Reservations:

- **Disaster recovery** — you can reserve capacity in a different Availability Zone or Region to ensure that the capacity you need is available during a fail over event.
- **Regulatory requirements** — you can use Capacity Reservations to satisfy regulatory requirements for high availability. Capacity Reservations ensure that capacity is in place to meet those requirements, even if you aren't utilizing those resources.
- **Events** — you can create Capacity Reservations before your business-critical events to ensure that you can scale when you need to.

You can create Capacity Reservations at any time, without entering into a one-year or three-year term commitment. The capacity becomes available and billing starts as soon as the Capacity Reservation

is provisioned in your account. When you no longer need the capacity assurance, cancel the Capacity Reservation to release the capacity and to stop incurring charges. You can also use the billing discounts offered by Savings Plans and Regional Reserved Instances to reduce the cost of a Capacity Reservation.

When you create a Capacity Reservation, you specify:

- The Availability Zone in which to reserve the capacity
- The number of instances for which to reserve capacity
- The instance attributes, including the instance type, tenancy, and platform/OS

Capacity Reservations can only be used by instances that match their attributes. By default, they are automatically used by running instances that match the attributes. If you don't have any running instances that match the attributes of the Capacity Reservation, it remains unused until you launch an instance with matching attributes.

Contents

- [Differences between Capacity Reservations, Reserved Instances, and Savings Plans \(p. 505\)](#)
- [Supported platforms \(p. 506\)](#)
- [Quotas \(p. 506\)](#)

- [Work with shared Capacity Reservations \(p. 525\)](#)
- [Capacity Reservation Fleets \(p. 529\)](#)
- [Monitoring Capacity Reservations \(p. 541\)](#)

Differences between Capacity Reservations, Reserved Instances, and Savings Plans

The following table highlights key differences between Capacity Reservations, Reserved Instances, and Savings Plans:

	Capacity Reservations	Zonal Reserved Instances	Regional Reserved Instances	Savings Plans
Term	No commitment required. Can be created and canceled as needed.	Requires a fixed one-year or three-year commitment		
Capacity benefit	Capacity reserved in a specific Availability Zone.		No capacity reserved.	
Billing discount	No billing discount. †	Provides a billing discount.		

	Capacity Reservations	Zonal Reserved Instances	Regional Reserved Instances	Savings Plans
Instance Limits	Your On-Demand Instance limits per Region apply.	Default is 20 per Availability Zone. You can request a limit increase.	Default is 20 per Region. You can request a limit increase.	No limit.

† You can combine Capacity Reservations with Savings Plans or Regional Reserved Instances to receive a discount.

For more information, see the following:

- [Reserved Instances \(p. 353\)](#)
- [Savings Plans User Guide](#)

Supported platforms

You must create the Capacity Reservation with the correct platform to ensure that it properly matches with your instances. Capacity Reservations support the following platforms:

- Windows
- Windows with SQL Server
- Windows with SQL Server Web
- Windows with SQL Server Standard
- Windows with SQL Server Enterprise

When you purchase a Capacity Reservation, you must specify the *platform* that represents the operating system for your instance.

- For Windows with SQL Standard, Windows with SQL Server Enterprise, and Windows with SQL Server Web, you must choose the specific platform.
- For all other Windows versions, excluding BYOL which is not supported, choose the **Windows** platform.

For more information about the supported Linux platforms, see [Supported platforms](#) in the *Amazon EC2 User Guide for Linux Instances*.

Quotas

The number of instances for which you are allowed to reserve capacity is based on your account's On-Demand Instance quota. You can reserve capacity for as many instances as that quota allows, minus the number of instances that are already running.

Quotas apply to running instances only. If your instance is pending, stopping, stopped, or hibernated, it does not count towards your quota.

Limitations

Before you create Capacity Reservations, take note of the following limitations and restrictions.

- Active and unused Capacity Reservations count toward your On-Demand Instance limits.

- Capacity Reservations are not transferable from one AWS account to another. However, you can share Capacity Reservations with other AWS accounts. For more information, see [Work with shared Capacity Reservations \(p. 525\)](#).
- Zonal Reserved Instance billing discounts do not apply to Capacity Reservations.
- Capacity Reservations can be created in cluster placement groups. Spread and partition placement groups are not supported.
- Capacity Reservations can't be used with Dedicated Hosts. Capacity Reservations can be used with Dedicated Instances.
- Capacity Reservations can't be used with Bring Your Own License (BYOL).
- Capacity Reservations do not ensure that a hibernated instance can resume after you try to start it.

Capacity Reservation pricing and billing

Topics

- [Pricing \(p. 507\)](#)
- [Billing \(p. 507\)](#)
- [Billing discounts \(p. 508\)](#)
- [Viewing your bill \(p. 508\)](#)

Pricing

Capacity Reservations are charged at the equivalent On-Demand rate whether you run instances in reserved capacity or not. If you do not use the reservation, this shows up as unused reservation on your Amazon EC2 bill. When you run an instance that matches the attributes of a reservation, you just pay for the instance and nothing for the reservation. There are no upfront or additional charges.

For example, if you create a Capacity Reservation for 20 m4.large Linux instances and run 15 m4.large Linux instances in the same Availability Zone, you will be charged for 15 active instances and for 5 unused instances in the reservation.

Billing discounts for Savings Plans and Regional Reserved Instances apply to Capacity Reservations. For more information, see [Billing discounts \(p. 508\)](#).

For more information, see [Amazon EC2 Pricing](#).

Billing

Billing starts as soon as the Capacity Reservation is provisioned in your account, and it continues while the Capacity Reservation remains provisioned in your account.

Capacity Reservations are billed at per-second granularity. This means that you are charged for partial hours. For example, if a Capacity Reservation remains provisioned in your account for 24 hours and 15 minutes, you are billed for 24.25 reservation hours.

The following example shows how a Capacity Reservation is billed. The Capacity Reservation is created for one m4.large Linux instance, which has an On-Demand rate of \$0.10 per usage hour. In this example, the Capacity Reservation is provisioned in the account for five hours. The Capacity Reservation is unused for the first hour, so it is billed for one unused hour at the m4.large instance type's standard On-Demand rate. In hours two through five, the Capacity Reservation is occupied by an m4.large instance. During this time, the Capacity Reservation accrues no charges, and the account is instead billed for the m4.large instance occupying it. In the sixth hour, the Capacity Reservation is canceled and the m4.large instance runs normally outside of the reserved capacity. For that hour, it is charged at the On-Demand rate of the m4.large instance type.

Hour	1	2	3	4	5	6	Total cost
Unused Capacity Reservation	\$0.10	\$0.00	\$0.00	\$0.00	\$0.00	\$0.00	\$0.10
On-demand Instance Usage	\$0.00	\$0.10	\$0.10	\$0.10	\$0.10	\$0.10	\$0.50
Hourly cost	\$0.10	\$0.10	\$0.10	\$0.10	\$0.10	\$0.10	\$0.60

Billing discounts

Billing discounts for Savings Plans and Regional Reserved Instances apply to Capacity Reservations. AWS automatically applies these discounts to Capacity Reservations that have matching attributes. When a Capacity Reservation is used by an instance, the discount is applied to the instance. Discounts are preferentially applied to instance usage before covering unused Capacity Reservations.

Billing discounts for zonal Reserved Instances do not apply to Capacity Reservations.

For more information, see the following:

- [Reserved Instances \(p. 353\)](#)
- [Savings Plans User Guide](#)

Viewing your bill

You can review the charges and fees to your account on the AWS Billing and Cost Management console.

- The **Dashboard** displays a spend summary for your account.
- On the **Bills** page, under **Details**, expand the **Elastic Compute Cloud** section and the Region to get billing information about your Capacity Reservations.

You can view the charges online, or you can download a CSV file. For more information, see [Capacity Reservation Line Items](#) in the *AWS Billing and Cost Management User Guide*.

Work with Capacity Reservations

To start using Capacity Reservations, you create the capacity reservation in the required Availability Zone. Then, you can launch instances into the reserved capacity, view its capacity utilization in real time, and increase or decrease its capacity as needed.

By default, Capacity Reservations automatically match new instances and running instances that have matching attributes (instance type, platform, and Availability Zone). This means that any instance with matching attributes automatically runs in the Capacity Reservation. However, you can also target a Capacity Reservation for specific workloads. This enables you to explicitly control which instances are allowed to run in that reserved capacity.

You can specify how the reservation ends. You can choose to cancel the Capacity Reservation or end it automatically at a specified time. If you specify an end time, the Capacity Reservation is canceled within an hour of the specified time. For example, if you specify 5/31/2019, 13:30:55, the Capacity Reservation is guaranteed to end between 13:30:55 and 14:30:55 on 5/31/2019. After a reservation ends, you can no longer target instances to the Capacity Reservation. Instances running in the reserved capacity continue to run uninterrupted. If instances targeting a Capacity Reservation are stopped, you cannot restart them until you remove their Capacity Reservation targeting preference or configure them to target a different Capacity Reservation.

Contents

- [Create a Capacity Reservation \(p. 509\)](#)

- [Launch instances into an existing Capacity Reservation \(p. 510\)](#)
- [Modify a Capacity Reservation \(p. 511\)](#)
- [Modify an instance's Capacity Reservation settings \(p. 512\)](#)
- [View a Capacity Reservation \(p. 513\)](#)
- [Cancel a Capacity Reservation \(p. 514\)](#)

Create a Capacity Reservation

If your request to create a Capacity Reservation succeeds, the capacity is available immediately. The capacity remains reserved for your use as long as the Capacity Reservation is active, and you can launch instances into it at any time. If the Capacity Reservation is open, new instances and existing instances that have matching attributes automatically run in the capacity of the Capacity Reservation. If the Capacity Reservation is targeted, instances must specifically target it to run in the reserved capacity.

Your request to create a Capacity Reservation could fail if one of the following is true:

- Amazon EC2 does not have sufficient capacity to fulfill the request. Either try again at a later time, try a different Availability Zone, or try a smaller request. If your application is flexible across instance types and sizes, try different instance attributes.
- The requested quantity exceeds your On-Demand Instance limit for the selected instance family. Increase your On-Demand Instance limit for the instance family and try again. For more information, see [On-Demand Instance quotas \(p. 352\)](#).

To create a Capacity Reservation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations**, and then choose **Create Capacity Reservation**.
3. On the Create a Capacity Reservation page, configure the following settings in the **Instance details** section. The instance type, platform, and Availability Zone of the instances that you launch must match the instance type, platform, and Availability Zone that you specify here or the Capacity Reservation is not applied. For example, if an open Capacity Reservation doesn't match, an instance launch that targets that Capacity Reservation explicitly will fail.
 - a. **Instance Type**—The type of instance to launch into the reserved capacity.
 - b. **Launch EBS-optimized instances**—Specify whether to reserve the capacity for EBS-optimized instances. This option is selected by default for some instance types. For more information about EBS-optimized instances, see [Amazon Elastic Block Store \(p. 1702\)](#).
 - c. **Platform**—The operating system for your instances. For more information, see [Supported platforms \(p. 506\)](#). For more information about the supported Linux platforms, see [Supported platforms](#) in the *Amazon EC2 User Guide for Linux Instances*.
 - d. **Availability Zone**—The Availability Zone in which to reserve the capacity.
 - e. **Tenancy**—Specify whether to run on shared hardware (default) or a dedicated instance.
 - f. **(Optional) Placement group ARN**—The ARN of the cluster placement group in which to create the Capacity Reservation. For more information, see [Capacity Reservations in cluster placement groups \(p. 519\)](#).
 - g. **Quantity**—The number of instances for which to reserve capacity. If you specify a quantity that exceeds your remaining On-Demand Instance limit for the selected instance type, the request is denied.
4. Configure the following settings in the **Reservation details** section:
 - a. **Reservation Ends**—Choose one of the following options:
 - **Manually**—Reserve the capacity until you explicitly cancel it.

- **Specific time**—Cancel the capacity reservation automatically at the specified date and time.
 - b. **Instance eligibility**—Choose one of the following options:
 - **open**—(Default) The Capacity Reservation matches any instance that has matching attributes (instance type, platform, and Availability Zone). If you launch an instance with matching attributes, it is placed into the reserved capacity automatically.
 - **targeted**—The Capacity Reservation only accepts instances that have matching attributes (instance type, platform, and Availability Zone), and that explicitly target the reservation.
5. Choose **Request reservation**.

To create a Capacity Reservation using the AWS CLI

Use the [create-capacity-reservation](#) command. For more information, see [Supported platforms \(p. 506\)](#). For more information about the supported Linux platforms, see [Supported platforms](#) in the *Amazon EC2 User Guide for Linux Instances*.

For example, the following command creates a Capacity Reservation that reserves capacity for three m5.2xlarge instances running Windows with SQL Server AMIs in the us-east-1a Availability Zone.

```
aws ec2 create-capacity-reservation --instance-type m5.2xlarge --instance-platform Windows with SQL Server --availability-zone us-east-1a --instance-count 3
```

Launch instances into an existing Capacity Reservation

When you launch an instance, you can specify whether to launch the instance into any open Capacity Reservation, into a specific Capacity Reservation, or into a group of Capacity Reservations. You can only launch an instance into a Capacity Reservation that has matching attributes (instance type, platform, and Availability Zone) and sufficient capacity. Alternatively, you can configure the instance to avoid running in a Capacity Reservation, even if you have an open Capacity Reservation that has matching attributes and available capacity.

Launching an instance into a Capacity Reservation reduces its available capacity by the number of instances launched. For example, if you launch three instances, the available capacity of the Capacity Reservation is reduced by three.

To launch instances into an existing Capacity Reservation using the console

1. Open the Launch Instance wizard by choosing **Launch Instances** from **Dashboard** or **Instances**.
2. Select an Amazon Machine Image (AMI) and an instance type.
3. Complete the **Configure Instance Details** page. For **Capacity Reservation**, choose one of the following options:
 - **None** — Prevents the instances from launching into a Capacity Reservation. The instances run in On-Demand capacity.
 - **Open** — Launches the instances into any Capacity Reservation that has matching attributes and sufficient capacity for the number of instances you selected. If there is no matching Capacity Reservation with sufficient capacity, the instance uses On-Demand capacity.
 - **Target by ID** — Launches the instances into the selected Capacity Reservation. If the selected Capacity Reservation does not have sufficient capacity for the number of instances you selected, the instance launch fails.
 - **Target by group** — Launches the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.

4. Complete the remaining steps to launch the instances.

To launch an instance into an existing Capacity Reservation using the AWS CLI

Use the [run-instances](#) command and specify the `--capacity-reservation-specification` parameter.

The following example launches a `t2.micro` instance into any open Capacity Reservation that has matching attributes and available capacity:

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro --key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-specification CapacityReservationPreference=open
```

The following example launches a `t2.micro` instance into a targeted Capacity Reservation:

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro --key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-specification CapacityReservationTarget={CapacityReservationId=cr-a1234567}
```

The following example launches a `t2.micro` instance into a Capacity Reservation group:

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro --key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-specification CapacityReservationTarget={CapacityReservationResourceGroupArn=arn:aws:resource-groups:us-west-1:123456789012:group/my-cr-group}
```

Modify a Capacity Reservation

You can change the attributes of an active Capacity Reservation after you have created it. You cannot modify a Capacity Reservation after it has expired or after you have explicitly canceled it.

When modifying a Capacity Reservation, you can only increase or decrease the quantity and change the way in which it is released. You cannot change the instance type, EBS optimization, platform, Availability Zone, or instance eligibility of a Capacity Reservation. If you need to modify any of these attributes, we recommend that you cancel the reservation, and then create a new one with the required attributes.

If you specify a new quantity that exceeds your remaining On-Demand Instance limit for the selected instance type, the update fails.

To modify a Capacity Reservation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations**, select the Capacity Reservation to modify, and then choose **Edit**.
3. Modify the **Quantity** or **Reservation ends** options as needed, and choose **Save changes**.

To modify a Capacity Reservation using the AWS CLI

Use the [modify-capacity-reservation](#) command:

For example, the following command modifies a Capacity Reservation to reserve capacity for eight instances.

```
aws ec2 modify-capacity-reservation --capacity-reservation-id cr-1234567890abcdef0 --instance-count 8
```

Modify an instance's Capacity Reservation settings

You can modify the following Capacity Reservation settings for a stopped instance at any time:

- Start in any Capacity Reservation that has matching attributes (instance type, platform, and Availability Zone) and available capacity.
- Start the instance in a specific Capacity Reservation.
- Start in any Capacity Reservation that has matching attributes and available capacity in a Capacity Reservation group
- Prevent the instance from starting in a Capacity Reservation.

To modify an instance's Capacity Reservation settings using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Instances** and select the instance to modify. Stop the instance if it is not already stopped.
3. Choose **Actions, Modify Capacity Reservation Settings**.
4. For **Capacity Reservation**, choose one of the following options:
 - **Open** — Launches the instances into any Capacity Reservation that has matching attributes and sufficient capacity for the number of instances you selected. If there is no matching Capacity Reservation with sufficient capacity, the instance uses On-Demand capacity.
 - **None** — Prevents the instances from launching into a Capacity Reservation. The instances run in On-Demand capacity.
 - **Specify Capacity Reservation** — Launches the instances into the selected Capacity Reservation. If the selected Capacity Reservation does not have sufficient capacity for the number of instances you selected, the instance launch fails.
 - **Specify Capacity Reservation group** — Launches the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.

To modify an instance's Capacity Reservation settings using the AWS CLI

Use the [modify-instance-capacity-reservation-attributes](#) command.

For example, the following command changes an instance's Capacity Reservation setting to open or none.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-id i-1234567890abcdef0  
--capacity-reservation-specification CapacityReservationPreference=none|open
```

For example, the following command modifies an instance to target a specific Capacity Reservation.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-  
id i-1234567890abcdef0 --capacity-reservation-specification  
CapacityReservationTarget={CapacityReservationId=cr-1234567890abcdef0}
```

For example, the following command modifies an instance to target a specific Capacity Reservation group.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-  
id i-1234567890abcdef0 --capacity-reservation-specification  
CapacityReservationTarget={CapacityReservationResourceGroupArn=arn:aws:resource-groups:us-  
west-1:123456789012:group/my-cr-group}
```

View a Capacity Reservation

Capacity Reservations have the following possible states:

- **active**—The capacity is available for use.
- **expired**—The Capacity Reservation expired automatically at the date and time specified in your reservation request. The reserved capacity is no longer available for your use.
- **cancelled**—The Capacity Reservation was canceled. The reserved capacity is no longer available for your use.
- **pending**—The Capacity Reservation request was successful but the capacity provisioning is still pending.
- **failed**—The Capacity Reservation request has failed. A request can fail due to request parameters that are not valid, capacity constraints, or instance limit constraints. You can view a failed request for 60 minutes.

Note

Due to the [eventual consistency](#) model followed by the Amazon EC2 APIs, after you create a Capacity Reservation, it can take up to 5 minutes for the console and the [describe-capacity-reservations](#) response to indicate that the Capacity Reservation is in the active state. During this time, the console and the describe-capacity-reservations response might indicate that the Capacity Reservation is in the pending state. However, the Capacity Reservation might already be available for use and you can attempt to launch instances into it.

To view your Capacity Reservations using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations** and select a Capacity Reservation to view.
3. Choose **View launched instances for this reservation**.

To view your Capacity Reservations using the AWS CLI

Use the [describe-capacity-reservations](#) command:

For example, the following command describes all Capacity Reservations.

```
aws ec2 describe-capacity-reservations
```

Example output.

```
{  
    "CapacityReservations": [  
        {  
            "CapacityReservationId": "cr-1234abcd56EXAMPLE ",  
            "EndDateType": "unlimited",  
            "AvailabilityZone": "eu-west-1a",  
            "InstanceMatchCriteria": "open",  
            "Tags": [],  
            "EphemeralStorage": false,  
            "CreateDate": "2019-08-16T09:03:18.000Z",  
            "AvailableInstanceCount": 1,  
            "InstancePlatform": "Linux/UNIX",  
            "TotalInstanceCount": 1,  
            "State": "active",  
            "Tenancy": "default",  
            "EbsOptimized": true,  
            "InstanceType": "a1.medium",  
            "OfferTermType": "standard",  
            "OfferingType": "capacity_reservation",  
            "OfferingId": "cr-offering-1234abcd56EXAMPLE ",  
            "OfferingRegion": "eu-west-1",  
            "OfferingTerm": "PT1M",  
            "OfferingStatus": "available",  
            "OfferingStatusReason": null  
        }  
    ]  
}
```

```
        "PlacementGroupArn": "arn:aws:ec2:us-east-1:123456789012:placement-group/MyPG"
    },
{
    "CapacityReservationId": "cr-abcdEXAMPLE9876ef",
    "EndDateType": "unlimited",
    "AvailabilityZone": "eu-west-1a",
    "InstanceMatchCriteria": "open",
    "Tags": [],
    "EphemeralStorage": false,
    "CreateDate": "2019-08-07T11:34:19.000Z",
    "AvailableInstanceCount": 3,
    "InstancePlatform": "Linux/UNIX",
    "TotalInstanceCount": 3,
    "State": "cancelled",
    "Tenancy": "default",
    "EbsOptimized": true,
    "InstanceType": "m5.large"
}
]
```

Cancel a Capacity Reservation

You can cancel a Capacity Reservation at any time if you no longer need the reserved capacity. When you cancel a Capacity Reservation, the capacity is released immediately, and it is no longer reserved for your use.

You can cancel empty Capacity Reservations and Capacity Reservations that have running instances. If you cancel a Capacity Reservation that has running instances, the instances continue to run normally outside of the capacity reservation at standard On-Demand Instance rates or at a discounted rate if you have a matching Savings Plan or Regional Reserved Instance.

After you cancel a Capacity Reservation, instances that target it can no longer launch. Modify these instances so that they either target a different Capacity Reservation, launch into any open Capacity Reservation with matching attributes and sufficient capacity, or avoid launching into a Capacity Reservation. For more information, see [Modify an instance's Capacity Reservation settings \(p. 512\)](#).

To cancel a Capacity Reservation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations** and select the Capacity Reservation to cancel.
3. Choose **Cancel reservation**, **Cancel reservation**.

To cancel a Capacity Reservation using the AWS CLI

Use the [cancel-capacity-reservation](#) command:

For example, the following command cancels a Capacity Reservation with an ID of cr-1234567890abcdef0.

```
aws ec2 cancel-capacity-reservation --capacity-reservation-id cr-1234567890abcdef0
```

Work with Capacity Reservation groups

You can use AWS Resource Groups to create logical collections of Capacity Reservations, called *resource groups*. A resource group is a logical grouping of AWS resources that are all in the same AWS Region. For more information about resource groups, see [What are resource groups?](#) in the *AWS Resource Groups User Guide*.

You can include Capacity Reservations that you own in your account, and Capacity Reservations that are shared with you by other AWS accounts in a single resource group. You can also include Capacity Reservations that have different attributes (instance type, platform, and Availability Zone) in a single resource group.

When you create resource groups for Capacity Reservations, you can target instances to a group of Capacity Reservations instead of an individual Capacity Reservation. Instances that target a group of Capacity Reservations match with any Capacity Reservation in the group that has matching attributes (instance type, platform, and Availability Zone) and available capacity. If the group does not have a Capacity Reservation with matching attributes and available capacity, the instances run using On-Demand capacity. If a matching Capacity Reservation is added to the targeted group at a later stage, the instance is automatically matched with and moved into its reserved capacity.

To prevent unintended use of Capacity Reservations in a group, configure the Capacity Reservations in the group to accept only instances that explicitly target the capacity reservation. To do this, set **Instance eligibility to targeted** (old console) or **Only instances that specify this reservation** (new console) when creating the Capacity Reservation using the Amazon EC2 console. When using the AWS CLI, specify `--instance-match-criteria targeted` when creating the Capacity Reservation. Doing this ensures that only instances that explicitly target the group, or a Capacity Reservation in the group, can run in the group.

If a Capacity Reservation in a group is canceled or expires while it has running instances, the instances are automatically moved to another Capacity Reservation in the group that has matching attributes and available capacity. If there are no remaining Capacity Reservations in the group that have matching attributes and available capacity, the instances run in On-Demand capacity. If a matching Capacity Reservation is added to the targeted group at a later stage, the instance is automatically moved into its reserved capacity.

Topics

- [Create a Capacity Reservation group \(p. 515\)](#)
- [Add a Capacity Reservation to a group \(p. 516\)](#)
- [View Capacity Reservations in a group \(p. 516\)](#)
- [View the groups to which a Capacity Reservation belongs \(p. 517\)](#)
- [Remove a Capacity Reservation from a group \(p. 518\)](#)
- [Delete a Capacity Reservation group \(p. 518\)](#)

Create a Capacity Reservation group

To create a group for Capacity Reservations

Use the `create-group` AWS CLI command. For name, provide a descriptive name for the group, and for configuration, specify two Type request parameters:

- `AWS::EC2::CapacityReservationPool` to ensure that the resource group can be targeted for instance launches
- `AWS::ResourceGroups::Generic` with `allowed-resource-types` set to `AWS::EC2::CapacityReservation` to ensure that the resource group accepts Capacity Reservations only

For example, the following command creates a group named `MyCRGroup`.

```
C:\> aws resource-groups create-group --name MyCRGroup --configuration
'{"Type":"AWS::EC2::CapacityReservationPool"}' '{"Type":"AWS::ResourceGroups::Generic",
"Parameters": [{"Name": "allowed-resource-types", "Values":
["AWS::EC2::CapacityReservation"]}]}'
```

The following shows example output.

```
{  
    "GroupConfiguration": {  
        "Status": "UPDATE_COMPLETE",  
        "Configuration": [  
            {  
                "Type": "AWS::EC2::CapacityReservationPool"  
            },  
            {  
                "Type": "AWS::ResourceGroups::Generic",  
                "Parameters": [  
                    {  
                        "Values": [  
                            "AWS::EC2::CapacityReservation"  
                        ],  
                        "Name": "allowed-resource-types"  
                    }  
                ]  
            }  
        ]  
    },  
    "Group": {  
        "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/MyCRGroup",  
        "Name": "MyCRGroup"  
    }  
}
```

Add a Capacity Reservation to a group

If you add a Capacity Reservation that is shared with you to a group, and that Capacity Reservation is unshared, it is automatically removed from the group.

To add a Capacity Reservation to a group

Use the [group-resources](#) AWS CLI command. For group, specify the name of the group to which to add the Capacity Reservations, and for resources, specify ARNs of the Capacity Reservations to add. To add multiple Capacity Reservations, separate the ARNs with a space. To get the ARNs of the Capacity Reservations to add, use the [describe-capacity-reservations](#) AWS CLI command and specify the IDs of the Capacity Reservations.

For example, the following command adds two Capacity Reservations to a group named MyCRGroup.

```
C:\> aws resource-groups group-resources --group MyCRGroup --resource-arns arn:aws:ec2:sa-  
east-1:123456789012:capacity-reservation/cr-1234567890abcdef1 arn:aws:ec2:sa-  
east-1:123456789012:capacity-reservation/cr-54321abcdef567890
```

The following shows example output.

```
{  
    "Failed": [],  
    "Succeeded": [  
        "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-1234567890abcdef1",  
        "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890"  
    ]  
}
```

View Capacity Reservations in a group

To view the Capacity Reservations in a specific group

Use the [list-group-resources](#) AWS CLI command. For group, specify the name of the group.

For example, the following command lists the Capacity Reservations in a group named MyCRGroup.

```
C:\> aws resource-groups list-group-resources --group MyCRGroup
```

The following shows example output.

```
{  
    "QueryErrors": [],  
    "ResourceIdentifiers": [  
        {  
            "ResourceType": "AWS::EC2::CapacityReservation",  
            "ResourceArn": "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/  
cr-1234567890abcdef1"  
        },  
        {  
            "ResourceType": "AWS::EC2::CapacityReservation",  
            "ResourceArn": "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/  
cr-54321abcdef567890"  
        }  
    ]  
}
```

Note

The command output includes Capacity Reservations that you own and Capacity Reservations that are shared with you.

View the groups to which a Capacity Reservation belongs

AWS CLI

To view the groups to which a specific Capacity Reservation has been added

Use the [get-groups-for-capacity-reservation](#) AWS CLI command.

For example, the following command lists the groups to which Capacity Reservation cr-1234567890abcdef1 has been added.

```
C:\> aws ec2 get-groups-for-capacity-reservation --capacity-reservation-  
id cr-1234567890abcdef1
```

The following shows example output.

```
{  
    "CapacityReservationGroups": [  
        {  
            "OwnerId": "123456789012",  
            "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/  
MyCRGroup"  
        }  
    ]  
}
```

Note

If you specify a Capacity Reservation that is shared with you, the command returns only Capacity Reservation groups that you own.

Amazon EC2 console

To view the groups to which a specific Capacity Reservation has been added

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**, select the Capacity Reservation to view, and then choose **View**.

The groups to which the Capacity Reservation has been added are listed in the **Groups** card.

Note

If you choose a Capacity Reservation that is shared with you, the console displays only Capacity Reservation groups that you own.

Remove a Capacity Reservation from a group

To remove a Capacity Reservation from a group

Use the [ungroup-resources](#) AWS CLI command. For group, specify the ARN of the group from which to remove the Capacity Reservation, and for resources specify the ARNs of the Capacity Reservations to remove. To remove multiple Capacity Reservations, separate the ARNs with a space.

The following example removes two Capacity Reservations from a group named MyCRGroup.

```
C:\> aws resource-groups ungroup-resources --group MyCRGroup --  
resource-arns arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/  
cr-0e154d26a16094dd arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/  
cr-54321abcdef567890
```

The following shows example output.

```
{  
    "Failed": [],  
    "Succeeded": [  
        "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-0e154d26a16094dd",  
        "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-54321abcdef567890"  
    ]  
}
```

Delete a Capacity Reservation group

To delete a group

Use the [delete-group](#) AWS CLI command. For group, provide the name of the group to delete.

For example, the following command deletes a group named MyCRGroup.

```
C:\> aws resource-groups delete-group --group MyCRGroup
```

The following shows example output.

```
{  
    "Group": {  
        "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/MyCRGroup",  
        "Name": "MyCRGroup"  
    }  
}
```

}

Capacity Reservations in cluster placement groups

You can create Capacity Reservations in a cluster placement group to reserve Amazon EC2 compute capacity for your workloads. Cluster placement groups offer the benefit of low network latency and high network throughput.

Creating a Capacity Reservation in a cluster placement group ensures that you have access to compute capacity in your cluster placement groups when you need it, for as long as you need it. This is ideal for reserving capacity for high-performance (HPC) workloads that require compute scaling. It allows you to scale your cluster down while ensuring that the capacity remains available for your use so that you can scale back up when needed.

Topics

- [Limitations \(p. 519\)](#)
- [Work with Capacity Reservations in cluster placement groups \(p. 519\)](#)

Limitations

Keep the following in mind when creating Capacity Reservations in cluster placement groups:

- You can't modify an existing Capacity Reservation that is not in a placement group to reserve capacity in a placement group. To reserve capacity in a placement group, you must create the Capacity Reservation in the placement group.
- After you create a Capacity Reservation in a placement group, you can't modify it to reserve capacity outside of the placement group.
- You can increase your reserved capacity in a placement group by modifying an existing Capacity Reservation in the placement group, or by creating additional Capacity Reservations in the placement group. However, you increase your chances of getting an insufficient capacity error.
- You can't share Capacity Reservations that have been created in a cluster placement group.
- You can't delete a cluster placement group that has active Capacity Reservations. You must cancel all Capacity Reservations in the cluster placement group before you can delete it.

Work with Capacity Reservations in cluster placement groups

To start using Capacity Reservations with cluster placement groups, perform the following steps.

Note

If you want to create a Capacity Reservation in an existing cluster placement group, skip Step 1. Then for Steps 2 and 3, specify the ARN of the existing cluster placement group. For more information about how to find the ARN of your existing cluster placement group, see [describe-placement-groups](#).

Topics

- [Step 1: \(Conditional\) Create a cluster placement group for use with a Capacity Reservation \(p. 519\)](#)
- [Step 2: Create a Capacity Reservation in a cluster placement group \(p. 520\)](#)
- [Step 3: Launch instances into the cluster placement group \(p. 521\)](#)

Step 1: (Conditional) Create a cluster placement group for use with a Capacity Reservation

Perform this step only if you need to create a new cluster placement group. To use an existing cluster placement group, skip this step and then for Steps 2 and 3, use the ARN of that cluster placement group.

For more information about how to find the ARN of your existing cluster placement group, see [describe-placement-groups](#).

You can create the cluster placement group using one of the following methods.

Console

To create a cluster placement group using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Placement Groups**, and then choose **Create placement group**.
3. For **Name**, specify a descriptive name for the placement group.
4. For **Placement strategy**, choose **Cluster**.
5. Choose **Create group**.
6. Find the ARN of the cluster placement group that you created.

```
$ aws ec2 describe-placement-groups --group-names placement_group_name
```

Make a note of the placement group ARN returned in the command output, because you'll need it for the next step.

AWS CLI

To create a cluster placement group using the AWS CLI

Use the [create-placement-group](#) command. For `--group-name`, specify a descriptive name for the placement group, and for `--strategy`, specify `cluster`.

The following example creates a placement group named MyPG that uses the `cluster` placement strategy.

```
C:\> aws ec2 create-placement-group \
--group-name MyPG \
--strategy cluster
```

Make a note of the placement group ARN returned in the command output, because you'll need it for the next step.

Step 2: Create a Capacity Reservation in a cluster placement group

You create a Capacity Reservation in a cluster placement group in the same way that you create any Capacity Reservation. However, you must also specify the ARN of the cluster placement group in which to create the Capacity Reservation. For more information, see [Create a Capacity Reservation \(p. 509\)](#).

Considerations

- The specified cluster placement group must be in the `available` state. If the cluster placement group is in the `pending`, `deleting`, or `deleted` state, the request fails.
- The Capacity Reservation and the cluster placement group must be in the same Availability Zone. If the request to create the Capacity Reservation specifies an Availability Zone that is different from that of the cluster placement group, the request fails.
- You can create Capacity Reservations only for instance types that are supported by cluster placement groups. If you specify an unsupported instance type, the request fails. For more information, see [Cluster placement group rules and limitations \(p. 1355\)](#).

- If you create an open Capacity Reservation in a cluster placement group and there are existing running instances that have matching attributes (placement group ARN, instance type, Availability Zone, platform, and tenancy), those instances automatically run in the Capacity Reservation.
- Your request to create a Capacity Reservation could fail if one of the following is true:
 - Amazon EC2 does not have sufficient capacity to fulfill the request. Either try again at a later time, try a different Availability Zone, or try a smaller capacity. If your workload is flexible across instance types and sizes, try different instance attributes.
 - The requested quantity exceeds your On-Demand Instance limit for the selected instance family. Increase your On-Demand Instance limit for the instance family and try again. For more information, see [On-Demand Instance quotas \(p. 352\)](#).

You can create the Capacity Reservation in the cluster placement group using one of the following methods.

Console

To create a Capacity Reservation using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **Capacity Reservations**, and then choose **Create Capacity Reservation**.
3. On the Create a Capacity Reservation page, configure the instance type, platform, Availability Zone, Tenancy, quantity, and end date as needed.
4. For **Placement group ARN**, specify the ARN of the cluster placement group in which to create the Capacity Reservation.
5. Choose **Create**.

For more information, see [Create a Capacity Reservation \(p. 509\)](#).

AWS CLI

To create a Capacity Reservation using the AWS CLI

Use the [create-capacity-reservation](#) command. For `--placement-group-arn`, specify the ARN of the cluster placement group in which to create the Capacity Reservation.

```
$ aws ec2 create-capacity-reservation \
--instance-type instance_type \
--instance-platform platform \
--availability-zone az \
--instance-count quantity \
--placement-group-arn placement_group_ARN
```

For more information, see [Create a Capacity Reservation \(p. 509\)](#).

Step 3: Launch instances into the cluster placement group

You launch an instance into a Capacity Reservation in a cluster placement group in the same way that you launch an instance into any Capacity Reservation. However, you must also specify the ARN of the cluster placement group in which to launch the instance. For more information, see [Create a Capacity Reservation \(p. 510\)](#).

Considerations

- If the Capacity Reservation is open, you do not need to specify the Capacity Reservation in the instance launch request. If the instance has attributes (placement group ARN, instance type,

Availability Zone, platform, and tenancy) that match a Capacity Reservation in the specified placement group, the instance automatically runs in the Capacity Reservation.

- If the Capacity Reservation accepts only targeted instance launches, you must specify the target Capacity Reservation in addition to the cluster placement group in the request.
- If the Capacity Reservation is in a Capacity Reservation group, you must specify the target Capacity Reservation group in addition to the cluster placement group in the request. For more information, see [Work with Capacity Reservation groups \(p. 514\)](#).

You can launch an instance into a Capacity Reservation in a cluster placement group using one of the following methods.

Console

To launch instances into an existing Capacity Reservation using the console

1. Open the Launch Instance wizard by choosing **Launch Instances** from the **Dashboard** or from the **Instances** screen.
2. Select an Amazon Machine Image (AMI) and an instance type.
3. Complete the **Configure Instance Details** page:
 - a. For **Placement group**, select **Add instance to placement group**, choose **Add to existing placement group**, and then select the cluster placement group in which to launch the instance.
 - b. For **Capacity Reservation**, choose one of the following options depending on the configuration of the Capacity Reservation:
 - **Open** — To launch the instances into any open Capacity Reservation in the cluster placement group that has matching attributes and sufficient capacity.
 - **Target by ID** — To launch the instances into a Capacity Reservation that accepts only targeted instance launches.
 - **Target by group** — To launch the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group.
4. Complete the remaining steps to launch the instances.

For more information, see [Launch instances into an existing Capacity Reservation \(p. 510\)](#).

AWS CLI

To launch instances into an existing Capacity Reservation using the AWS CLI

Use the [run-instances](#) command. If you need to target a specific Capacity Reservation or a Capacity Reservation group, specify the `--capacity-reservation-specification` parameter. For `--placement`, specify the `GroupName` parameter and then specify the name of the placement group that you created in the previous steps.

The following command launches an instance into a targeted Capacity Reservation in a cluster placement group.

```
$ aws ec2 run-instances \
--image-id ami_id \
--count quantity \
--instance-type instance_type \
--key-name key_pair_name \
--subnet-id subnetid \
--capacity-reservation-specification
  CapacityReservationTarget={CapacityReservationId=capacity_reservation_id} \
```

```
--placement "GroupName=cluster_placement_group_name"
```

For more information, see [Launch instances into an existing Capacity Reservation \(p. 510\)](#).

Capacity Reservations in Local Zones

A Local Zone is an extension of an AWS Region that is geographically close to your users. Resources created in a Local Zone can serve local users with very low-latency communications. For more information, see [AWS Local Zones](#).

You can extend a VPC from its parent AWS Region into a Local Zone by creating a new subnet in that Local Zone. When you create a subnet in a Local Zone, your VPC is extended to that Local Zone. The subnet in the Local Zone operates the same as the other subnets in your VPC.

By using Local Zones, you can place Capacity Reservations in multiple locations that are closer to your users. You create and use Capacity Reservations in Local Zones in the same way that you create and use Capacity Reservations in regular Availability Zones. The same features and instance matching behavior apply. For more information about the pricing models that are supported in Local Zones, see [AWS Local Zones FAQs](#).

Considerations

You can't use Capacity Reservation groups in a Local Zone.

To use a Capacity Reservation in a Local Zone

1. Enable the Local Zone for use in your AWS account. For more information, see [Opt in to Local Zones \(p. 1231\)](#).
2. Create a Capacity Reservation in the Local Zone. For **Availability Zone**, choose the Local Zone. The Local Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example us-west-2-lax-1a. For more information, see [Create a Capacity Reservation \(p. 509\)](#).
3. Create a subnet in the Local Zone. For **Availability Zone**, choose the Local Zone. For more information, see [Create a subnet in your VPC](#) in the *Amazon VPC User Guide*.
4. Launch an instance. For **Subnet**, choose the subnet in the Local Zone (for example subnet-123abc | us-west-2-lax-1a), and for **Capacity Reservation**, choose the specification (either open or target it by ID) that's required for the Capacity Reservation that you created in the Local Zone. For more information, see [Launch instances into an existing Capacity Reservation \(p. 510\)](#).

Capacity Reservations in Wavelength Zones

AWS Wavelength enables developers to build applications that deliver ultra-low latencies to mobile devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks. You can extend an Amazon Virtual Private Cloud (VPC) to one or more Wavelength Zones. You can then use AWS resources like Amazon EC2 instances to run applications that require ultra-low latency and a connection to AWS services in the Region. For more information, see [AWS Wavelength Zones](#).

When you create On-Demand Capacity Reservations, you can choose the Wavelength Zone and you can launch instances into a Capacity Reservation in a Wavelength Zone by specifying the subnet associated with the Wavelength Zone. A Wavelength Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example us-east-1-wl1-bos-wlz-1.

Wavelength Zones are not available in every Region. For information about the Regions that support Wavelength Zones, see [Available Wavelength Zones](#) in the *AWS Wavelength Developer Guide*.

Considerations

You can't use Capacity Reservation groups in a Wavelength Zone.

To use a Capacity Reservation in a Wavelength Zone

1. Enable the Wavelength Zone for use in your AWS account. For more information, see [Enable Wavelength Zones](#) in the *Amazon EC2 User Guide for Linux Instances*.
2. Create a Capacity Reservation in the Wavelength Zone. For **Availability Zone**, choose the Wavelength. The Wavelength is represented by an AWS Region code followed by an identifier that indicates the location, for example us-east-1-wl1-bos-wlz-1. For more information, see [Create a Capacity Reservation \(p. 509\)](#).
3. Create a subnet in the Wavelength Zone. For **Availability Zone**, choose the Wavelength Zone. For more information, see [Create a subnet in your VPC](#) in the *Amazon VPC User Guide*.
4. Launch an instance. For **Subnet**, choose the subnet in the Wavelength Zone (for example subnet-123abc | us-east-1-wl1-bos-wlz-1), and for **Capacity Reservation**, choose the specification (either open or target it by ID) that's required for the Capacity Reservation that you created in the Wavelength. For more information, see [Launch instances into an existing Capacity Reservation \(p. 510\)](#).

Capacity Reservations on AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to customer premises. By providing local access to AWS managed infrastructure, AWS Outposts enables customers to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region.

You can create Capacity Reservations on Outposts that you have created in your account. This allows you to reserve compute capacity on an Outpost at your site. You create and use Capacity Reservations on Outposts in the same way that you create and use Capacity Reservations in regular Availability Zones. The same features and instance matching behavior apply.

You can also share Capacity Reservations on Outposts with other AWS accounts within your organization using AWS Resource Access Manager. For more information about sharing Capacity Reservations, see [Work with shared Capacity Reservations \(p. 525\)](#).

Prerequisite

You must have an Outpost installed at your site. For more information, see [Create an Outpost and order Outpost capacity](#) in the *AWS Outposts User Guide*.

Considerations

- You can't use Capacity Reservation groups on an Outpost.

To use a Capacity Reservation on an Outpost

1. Create a subnet on the Outpost. For more information, see [Create a subnet](#) in the *AWS Outposts User Guide*.
2. Create a Capacity Reservation on the Outpost.
 - a. Open the AWS Outposts console at <https://console.aws.amazon.com/outposts/>.
 - b. In the navigation pane, choose **Outposts**, and then choose **Actions, Create Capacity Reservation**.

- c. Configure the Capacity Reservation as needed and then choose **Create**. For more information, see [Create a Capacity Reservation \(p. 509\)](#).

Note

The **Instance Type** drop-down lists only instance types that are supported by the selected Outpost, and the **Availability Zone** drop-down lists only the Availability Zone with which the selected Outpost is associated.

3. Launch an instance into the Capacity Reservation. For **Subnet** choose the subnet that you created in Step 1, and for **Capacity Reservation**, select the Capacity Reservation that you created in Step 2. For more information, see [Launch an instance on the Outpost](#) in the *AWS Outposts User Guide*.

Work with shared Capacity Reservations

Capacity Reservation sharing enables Capacity Reservation owners to share their reserved capacity with other AWS accounts or within an AWS organization. This enables you to create and manage Capacity Reservations centrally, and share the reserved capacity across multiple AWS accounts or within your AWS organization.

In this model, the AWS account that owns the Capacity Reservation (owner) shares it with other AWS accounts (consumers). Consumers can launch instances into Capacity Reservations that are shared with them in the same way that they launch instances into Capacity Reservations that they own in their own account. The Capacity Reservation owner is responsible for managing the Capacity Reservation and the instances that they launch into it. Owners cannot modify instances that consumers launch into Capacity Reservations that they have shared. Consumers are responsible for managing the instances that they launch into Capacity Reservations shared with them. Consumers cannot view or modify instances owned by other consumers or by the Capacity Reservation owner.

A Capacity Reservation owner can share a Capacity Reservation with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization
- Its entire AWS organization

Contents

- [Prerequisites for sharing Capacity Reservations \(p. 525\)](#)
- [Related services \(p. 526\)](#)
- [Share across Availability Zones \(p. 526\)](#)
- [Share a Capacity Reservation \(p. 526\)](#)
- [Stop sharing a Capacity Reservation \(p. 527\)](#)
- [Identify and view a shared Capacity Reservation \(p. 528\)](#)
- [View shared Capacity Reservation usage \(p. 528\)](#)
- [Shared Capacity Reservation permissions \(p. 529\)](#)
- [Billing and metering \(p. 529\)](#)
- [Instance limits \(p. 529\)](#)

Prerequisites for sharing Capacity Reservations

- To share a Capacity Reservation, you must own it in your AWS account. You cannot share a Capacity Reservation that has been shared with you.
- You can only share Capacity Reservations for shared tenancy instances. You cannot share Capacity Reservations for dedicated tenancy instances.

- Capacity Reservation sharing is not available to new AWS accounts or AWS accounts that have a limited billing history.
- To share a Capacity Reservation with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see [Enable Sharing with AWS Organizations](#) in the *AWS RAM User Guide*.

Related services

Capacity Reservation sharing integrates with AWS Resource Access Manager (AWS RAM). AWS RAM is a service that enables you to share your AWS resources with any AWS account or through AWS Organizations. With AWS RAM, you share resources that you own by creating a *resource share*. A resource share specifies the resources to share, and the consumers with whom to share them. Consumers can be individual AWS accounts, or organizational units or an entire organization from AWS Organizations.

For more information about AWS RAM, see the [AWS RAM User Guide](#).

Share across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone `us-east-1a` for your AWS account might not have the same location as `us-east-1a` for another AWS account.

To identify the location of your Capacity Reservations relative to your accounts, you must use the *Availability Zone ID* (AZ ID). The AZ ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, `use1-az1` is an AZ ID for the `us-east-1` Region and it is the same location in every AWS account.

To view the AZ IDs for the Availability Zones in your account

1. Open the AWS RAM console at <https://console.aws.amazon.com/ram>.
2. The AZ IDs for the current Region are displayed in the **Your AZ ID** panel on the right-hand side of the screen.

Share a Capacity Reservation

When you share a Capacity Reservation that you own with other AWS accounts, you enable them to launch instances into your reserved capacity. If you share an open Capacity Reservation, keep the following in mind as it could lead to unintended Capacity Reservation usage:

- If consumers have running instances that match the attributes of the Capacity Reservation, have the `CapacityReservationPreference` parameter set to `open`, and are not yet running in reserved capacity, they automatically use the shared Capacity Reservation.
- If consumers launch instances that have matching attributes (instance type, platform, and Availability Zone) and have the `CapacityReservationPreference` parameter set to `open`, they automatically launch into the shared Capacity Reservation.

To share a Capacity Reservation, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared. When you share a Capacity Reservation using the Amazon EC2 console, you add it to an existing resource share. To add the Capacity Reservation to a new resource share, you must create the resource share using the [AWS RAM console](#).

If you are part of an organization in AWS Organizations and sharing within your organization is enabled, consumers in your organization are granted access to the shared Capacity Reservation if the [prerequisites](#)

[for sharing \(p. 525\)](#) are met. If the Capacity Reservation is shared with external accounts, they receive an invitation to join the resource share and are granted access to the shared Capacity Reservation after accepting the invitation.

Important

Before launching instances into a Capacity Reservation that is shared with you, verify that you have access to the shared Capacity Reservation by viewing it in the console or by describing it using the [describe-capacity-reservations](#) AWS CLI command. If you can view the shared Capacity Reservation in the console or describe it using the AWS CLI, it is available for your use and you can launch instances into it. If you attempt to launch instances into the Capacity Reservation and it is not accessible due to a sharing failure, the instances will launch into On-Demand capacity.

You can share a Capacity Reservation that you own using the Amazon EC2 console, AWS RAM console, or the AWS CLI.

To share a Capacity Reservation that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**.
3. Choose the Capacity Reservation to share and choose **Actions, Share reservation**.
4. Select the resource share to which to add the Capacity Reservation and choose **Share Capacity Reservation**.

It could take a few minutes for consumers to get access to the shared Capacity Reservation.

To share a Capacity Reservation that you own using the AWS RAM console

See [Creating a Resource Share](#) in the *AWS RAM User Guide*.

To share a Capacity Reservation that you own using the AWS CLI

Use the [create-resource-share](#) command.

Stop sharing a Capacity Reservation

The Capacity Reservation owner can stop sharing a Capacity Reservation at any time. The following rules apply:

- Instances owned by consumers that were running in the shared capacity at the time sharing stops continue to run normally outside of the reserved capacity, and the capacity is restored to the Capacity Reservation subject to Amazon EC2 capacity availability.
- Consumers with whom the Capacity Reservation was shared can no longer launch new instances into the reserved capacity.

To stop sharing a Capacity Reservation that you own, you must remove it from the resource share. You can do this using the Amazon EC2 console, AWS RAM console, or the AWS CLI.

To stop sharing a Capacity Reservation that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**.
3. Select the Capacity Reservation and choose the **Sharing** tab.
4. The **Sharing** tab lists the resource shares to which the Capacity Reservation has been added. Select the resource share from which to remove the Capacity Reservation and choose **Remove from resource share**.

To stop sharing a Capacity Reservation that you own using the AWS RAM console

See [Updating a Resource Share](#) in the *AWS RAM User Guide*.

To stop sharing a Capacity Reservation that you own using the AWS CLI

Use the [disassociate-resource-share](#) command.

Identify and view a shared Capacity Reservation

Important

Before launching instances into a Capacity Reservation that is shared with you, verify that you have access to the shared Capacity Reservation by viewing it in the console or by describing it using the AWS CLI. If you can view the shared Capacity Reservation in the console or describe it using the AWS CLI, it is available for your use and you can launch instances into it. If you attempt to launch instances into the Capacity Reservation and it is not accessible due to a sharing failure, the instance will launch into On-Demand capacity.

Owners and consumers can identify and view shared Capacity Reservations using the Amazon EC2 console and AWS CLI.

To identify a shared Capacity Reservation using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**. The screen lists Capacity Reservations that you own and Capacity Reservations that are shared with you. The **Owner** column shows the AWS account ID of the Capacity Reservation owner. (me) next to the AWS account ID indicates that you are the owner.

To identify a shared Capacity Reservation using the AWS CLI

Use the [describe-capacity-reservations](#) command. The command returns the Capacity Reservations that you own and Capacity Reservations that are shared with you. OwnerId shows the AWS account ID of the Capacity Reservation owner.

View shared Capacity Reservation usage

The owner of a shared Capacity Reservation can view its usage at any time using the Amazon EC2 console and the AWS CLI.

To view Capacity Reservation usage using the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Capacity Reservations**.
3. Select the Capacity Reservation for which to view the usage and choose the **Usage** tab.

The **AWS account ID** column shows the account IDs of the consumers currently using the Capacity Reservation. The **Launched instances** column shows the number of instances each consumer currently has running in the reserved capacity.

To view Capacity Reservation usage using the AWS CLI

Use the [get-capacity-reservation-usage](#) command. AccountId shows the account ID of the account using the Capacity Reservation. UsedInstanceCount shows the number of instances the consumer currently has running in the reserved capacity.

Shared Capacity Reservation permissions

Permissions for owners

Owners are responsible for managing and canceling their shared Capacity Reservations. Owners cannot modify instances running in the shared Capacity Reservation that are owned by other accounts. Owners remain responsible for managing instances that they launch into the shared Capacity Reservation.

Permissions for consumers

Consumers are responsible for managing their instances that are running the shared Capacity Reservation. Consumers cannot modify the shared Capacity Reservation in any way, and they cannot view or modify instances that are owned by other consumers or the Capacity Reservation owner.

Billing and metering

There are no additional charges for sharing Capacity Reservations.

The Capacity Reservation owner is billed for instances that they run inside the Capacity Reservation and for unused reserved capacity. Consumers are billed for the instances that they run inside the shared Capacity Reservation.

If the Capacity Reservation owner belongs to a different payer account and the Capacity Reservation is covered by a Regional Reserved Instance or a Savings Plan, the Capacity Reservation owner continues to be billed for the Regional Reserved Instance or Savings Plan. In these cases, the Capacity Reservation owner pays for the Regional Reserved Instance or Savings Plan, and consumers are billed for the instances that they run in the shared Capacity Reservation.

Instance limits

All Capacity Reservation usage counts toward the Capacity Reservation owner's On-Demand Instance limits. This includes:

- Unused reserved capacity
- Usage by instances owned by the Capacity Reservation owner
- Usage by instances owned by consumers

Instances launched into the shared capacity by consumers count towards the Capacity Reservation owner's On-Demand Instance limit. Consumers' instance limits are a sum of their own On-Demand Instance limits and the capacity available in the shared Capacity Reservations to which they have access.

Capacity Reservation Fleets

An *On-Demand Capacity Reservation Fleet* is a group of Capacity Reservations.

A Capacity Reservation Fleet request contains all of the configuration information that's needed to launch a Capacity Reservation Fleet. Using a single request, you can reserve large amounts of Amazon EC2 capacity for your workload across multiple instance types, up to a target capacity that you specify.

After you create a Capacity Reservation Fleet, you can manage the Capacity Reservations in the fleet collectively by modifying or canceling the Capacity Reservation Fleet.

Topics

- [How Capacity Reservation Fleets work \(p. 175\)](#)
- [Considerations \(p. 343\)](#)
- [Pricing \(p. 530\)](#)
- [Capacity Reservation Fleet concepts \(p. 531\)](#)

- [Work with Capacity Reservation Fleets \(p. 532\)](#)
- [Example Capacity Reservation Fleet configurations \(p. 538\)](#)
- [Using service-linked roles for Capacity Reservation Fleet \(p. 539\)](#)

How Capacity Reservation Fleets work

When you create a Capacity Reservation Fleet, the Fleet attempts to create individual Capacity Reservations to meet the total target capacity that you specified in the Fleet request.

The number of instances for which the Fleet reserves capacity depends on the [*total target capacity \(p. 531\)*](#) and the [*instance type weights \(p. 531\)*](#) that you specify. The instance type for which it reserves capacity depends on the [*allocation strategy \(p. 531\)*](#) and [*instance type priorities \(p. 532\)*](#) that you use.

If there is insufficient capacity at the time the Fleet is created, and it is unable to immediately meet its total target capacity, the Fleet asynchronously attempts to create Capacity Reservations until it has reserved the requested amount of capacity.

When the Fleet reaches its total target capacity, it attempts to maintain that capacity. If a Capacity Reservation in the Fleet is cancelled, the Fleet automatically creates one or more Capacity Reservations, depending on your Fleet configuration, to replace the lost capacity and to maintain its total target capacity.

The Capacity Reservations in the Fleet can't be managed individually. They must be managed collectively by modifying the Fleet. When you modify a Fleet, the Capacity Reservations in the Fleet are automatically updated to reflect the changes.

Currently, Capacity Reservation Fleets support the open instance matching criteria, and all Capacity Reservations launched by a Fleet automatically use this instance matching criteria. With this criteria, new instances and existing instances that have matching attributes (instance type, platform, and Availability Zone) automatically run in the Capacity Reservations created by a Fleet. Capacity Reservation Fleets do not support target instance matching criteria.

Considerations

Keep the following in mind when working with Capacity Reservation Fleets:

- A Capacity Reservation Fleet can be created, modified, viewed, and cancelled using the AWS CLI and AWS API.
- The Capacity Reservations in a Fleet can't be managed individually. They must be managed collectively by modifying or cancelling the Fleet.
- A Capacity Reservation Fleet can't span across Regions.
- A Capacity Reservation Fleet can't span across Availability Zones.
- Capacity Reservations created by a Capacity Reservation Fleet are automatically tagged with the following AWS generated tag:
 - Key — `aws:ec2-capacity-reservation-fleet`
 - Value — `fleet_id`

You can use this tag to identify Capacity Reservations that were created by a Capacity Reservation Fleet.

Pricing

There are no additional charges for using Capacity Reservation Fleets. You are billed for the individual Capacity Reservations that are created by your Capacity Reservation Fleets. For more information about how Capacity Reservations are billed, see [Capacity Reservation pricing and billing \(p. 507\)](#).

Capacity Reservation Fleet concepts

This topic describes some of the concepts of Capacity Reservation Fleets.

Topics

- [Total target capacity \(p. 531\)](#)
- [Allocation strategy \(p. 531\)](#)
- [Instance type weight \(p. 531\)](#)
- [Instance type priority \(p. 532\)](#)

Total target capacity

The *total target capacity* defines the total amount of compute capacity that the Capacity Reservation Fleet reserves. You specify the total target capacity when you create the Capacity Reservation Fleet. After the Fleet has been created, Amazon EC2 automatically creates Capacity Reservations to reserve capacity up to the total target capacity.

The number of instances for which the Capacity Reservation Fleet reserves capacity is determined by the total target capacity and the *instance type weight* that you specify for each instance type in the Capacity Reservation Fleet ($\text{total target capacity}/\text{instance type weight} = \text{number of instances}$).

You can assign a total target capacity based on units that are meaningful to your workload. For example, if your workload requires a certain number of vCPUs, you can assign the total target capacity based on the number of vCPUs required. If your workload requires 2048 vCPUs, specify a total target capacity of 2048 and then assign instance type weights based on the number of vCPUs provided by the instance types in the Fleet. For an example, see [Instance type weight \(p. 531\)](#).

Allocation strategy

The allocation strategy for your Capacity Reservation Fleet determines how it fulfills your request for reserved capacity from the instance type specifications in the Capacity Reservation Fleet configuration.

Currently, only the prioritized allocation strategy is supported. With this strategy, the Capacity Reservation Fleet creates Capacity Reservations using the priorities that you have assigned to each of the instance type specifications in the Capacity Reservation Fleet configuration. Lower priority values indicate higher priority for use. For example, say you create a Capacity Reservation Fleet that uses the following instance types and priorities:

- m4.16xlarge — priority = 1
- m5.16xlarge — priority = 3
- m5.24xlarge — priority = 2

The Fleet first attempts to create Capacity Reservations for m4.16xlarge. If Amazon EC2 has insufficient m4.16xlarge capacity, the Fleet attempts to create Capacity Reservations for m5.24xlarge. If Amazon EC2 has insufficient m5.24xlarge capacity, the Fleet creates Capacity Reservations for m5.16xlarge.

Instance type weight

The *instance type weight* is a weight that you assign to each instance type in the Capacity Reservation Fleet. The weight determines how many units of capacity each instance of that specific instance type counts toward the Fleet's *total target capacity*.

You can assign weights based on units that are meaningful to your workload. For example, if your workload requires a certain number of vCPUs, you can assign weights based on the number of vCPUs provided by each instance type in the Capacity Reservation Fleet. In this case, if you create a Capacity

Reservation Fleet using m4.16xlarge and m5.24xlarge instances, you would assign weights that correspond to the number of vCPUs for each instance as follows:

- m4.16xlarge — 64 vCPUs, weight = 64 units
- m5.24xlarge — 96 vCPUs, weight = 96 units

The instance type weight determines the number of instances for which the Capacity Reservation Fleet reserves capacity. For example, if a Capacity Reservation Fleet with a total target capacity of 384 units uses the instance types and weights in the preceding example, the Fleet could reserve capacity for 6 m4.16xlarge instances (384 total target capacity/64 instance type weight=6 instances), or 4 m5.24xlarge instances (384 / 96 = 4).

If you do not assign instance type weights, or if you assign an instance type weight of 1, the total target capacity is based purely on instance count. For example, if a Capacity Reservation Fleet with a total target capacity of 384 units uses the instance types in the preceding example, but omits the weights or specifies a weight of 1 for both instance types, the Fleet could reserve capacity for either 384 m4.16xlarge instances or 384 m5.24xlarge instances.

Instance type priority

The *instance type priority* is a value that you assign to the instance types in the Fleet. The priorities are used to determine which of the instance types specified for the Fleet should be prioritized for use.

Lower priority values indicate a higher priority for use.

Work with Capacity Reservation Fleets

Topics

- [Before you begin \(p. 532\)](#)
- [Capacity Reservation Fleet states \(p. 532\)](#)
- [Create a Capacity Reservation Fleet \(p. 533\)](#)
- [View a Capacity Reservation Fleet \(p. 534\)](#)
- [Modify a Capacity Reservation Fleet \(p. 536\)](#)
- [Cancel a Capacity Reservation Fleet \(p. 537\)](#)

Before you begin

Before you create a Capacity Reservation Fleet:

1. Determine the amount of compute capacity that is needed by your workload.
2. Decide on the instance types and Availability Zones that you want to use.
3. Assign each instance type a priority based on your needs and preferences. For more information, see [Instance type priority \(p. 532\)](#).
4. Create a capacity weighting system that makes sense for your workload. Assign a weight to each instance type and determine your total target capacity. For more information, see [Instance type weight \(p. 531\)](#) and [Total target capacity \(p. 531\)](#).
5. Determine whether you need the Capacity Reservation indefinitely or only for a specific period of time.

Capacity Reservation Fleet states

A Capacity Reservation Fleet can be in one of the following states:

- submitted — The Capacity Reservation Fleet request has been submitted and Amazon EC2 is preparing to create the Capacity Reservations.
- modifying — The Capacity Reservation Fleet is being modified. The Fleet remains in this state until the modification is complete.
- active — The Capacity Reservation Fleet has fulfilled its total target capacity and it is attempting to maintain this capacity. The Fleet remains in this state until it is modified or deleted.
- partially_fulfilled — The Capacity Reservation Fleet has partially fulfilled its total target capacity. There is insufficient Amazon EC2 capacity to fulfill the total target capacity. The Fleet is attempting to asynchronously fulfill its total target capacity.
- expiring — The Capacity Reservation Fleet has reached its end date and it is in the process of expiring. One or more of its Capacity Reservations might still be active.
- expired — The Capacity Reservation Fleet has reached its end date. The Fleet and its Capacity Reservations are expired. The Fleet can't create new Capacity Reservations.
- cancelling — The Capacity Reservation Fleet is in the process of being cancelled. One or more of its Capacity Reservations might still be active.
- cancelled — The Capacity Reservation Fleet has been manually cancelled. The Fleet and its Capacity Reservations are cancelled and the Fleet can't create new Capacity Reservations.
- failed — The Capacity Reservation Fleet failed to reserve capacity for the specified instance types.

Create a Capacity Reservation Fleet

When you create a Capacity Reservation Fleet it automatically creates Capacity Reservations for the instance types specified in the Fleet request, up to the specified total target capacity. The number of instances for which the Capacity Reservation Fleet reserves capacity depends on the total target capacity and instance type weights that you specify in the request. For more information, see [Instance type weight \(p. 531\)](#) and [Total target capacity \(p. 531\)](#).

When you create the Fleet, you must specify the instance types to use and a priority for each of those instance types. For more information, see [Allocation strategy \(p. 531\)](#) and [Instance type priority \(p. 532\)](#).

Note

The **AWSServiceRoleForEC2CapacityReservationFleet** service-linked role is automatically created in your account the first time that you create a Capacity Reservation Fleet. For more information, see [Using service-linked roles for Capacity Reservation Fleet \(p. 539\)](#).

Currently, Capacity Reservation Fleets support the open instance matching criteria only.

You can create a Capacity Reservation Fleet using the command line only.

To create a Capacity Reservation Fleet

Use the [create-capacity-reservation-fleet](#) AWS CLI command.

```
C:\> aws ec2 create-capacity-reservation-fleet \
--total-target-capacity capacity_units \
--allocation-strategy prioritized \
--instance-match-criteria open \
--tenancy dedicated/default \
--end-date yyyy-mm-ddThh:mm:ss.000Z \
--instance-type-specifications file://instanceTypeSpecification.json
```

The following is the contents of *instanceTypeSpecification.json*.

```
[  
  {  
    "InstanceType": "instance_type",
```

```
    "InstancePlatform": "platform",
    "Weight": instance_type_weight,
    "AvailabilityZone": "availability_zone",
    "AvailabilityZoneId": "az_id",
    "EbsOptimized": true/false,
    "Priority" : instance_type_priority
}
]
```

Expected output.

```
{
    "Status": "status",
    "TotalFulfilledCapacity": fulfilled_capacity,
    "CapacityReservationFleetId": "cr_fleet_id",
    "TotalTargetCapacity": capacity_units
}
```

Example

```
C:\> aws ec2 create-capacity-reservation-fleet \
--total-target-capacity 24 \
--allocation-strategy prioritized \
--instance-match-criteria open \
--tenancy default \
--end-date 2021-12-31T23:59:59.000Z \
--instance-type-specifications file://instanceTypeSpecification.json
```

instanceTypeSpecification.json

```
[
    {
        "InstanceType": "m5.xlarge",
        "InstancePlatform": "Linux/UNIX",
        "Weight": 3.0,
        "AvailabilityZone": "us-east-1a",
        "EbsOptimized": true,
        "Priority" : 1
    }
]
```

Example output.

```
{
    "Status": "submitted",
    "TotalFulfilledCapacity": 0.0,
    "CapacityReservationFleetId": "crf-abcdef01234567890",
    "TotalTargetCapacity": 24
}
```

View a Capacity Reservation Fleet

You can view configuration and capacity information for a Capacity Reservation Fleet at any time. Viewing a Fleet also provides details about the individual Capacity Reservations that are inside the Fleet.

You can view a Capacity Reservation Fleet using the command line only.

To view a Capacity Reservation Fleet

Use the [describe-capacity-reservation-fleets](#) AWS CLI command.

```
C:\> aws ec2 describe-capacity-reservation-fleets \
--capacity-reservation-fleet-ids cr_fleet_ids
```

Expected output

```
{
    "CapacityReservationFleets": [
        {
            "Status": "status",
            "EndDate": "yyyy-mm-ddThh:mm:ss.000Z",
            "InstanceMatchCriteria": "open",
            "Tags": [],
            "CapacityReservationFleetId": "cr_fleet_id",
            "Tenancy": "dedicated/default",
            "InstanceTypeSpecifications": [
                {
                    "CapacityReservationId": "cr1_id",
                    "AvailabilityZone": "cr1_availability_zone",
                    "FulfilledCapacity": "cr1_used_capacity",
                    "Weight": "cr1_instance_type_weight",
                    "CreateDate": "yyyy-mm-ddThh:mm:ss.000Z",
                    "InstancePlatform": "cr1_platform",
                    "TotalInstanceCount": "cr1_number_of_instances",
                    "Priority": "cr1_instance_type_priority",
                    "EbsOptimized": "true/false",
                    "InstanceType": "cr1_instance_type"
                },
                {
                    "CapacityReservationId": "cr2_id",
                    "AvailabilityZone": "cr2_availability_zone",
                    "FulfilledCapacity": "cr2_used_capacity",
                    "Weight": "cr2_instance_type_weight",
                    "CreateDate": "yyyy-mm-ddThh:mm:ss.000Z",
                    "InstancePlatform": "cr2_platform",
                    "TotalInstanceCount": "cr2_number_of_instances",
                    "Priority": "cr2_instance_type_priority",
                    "EbsOptimized": "true/false",
                    "InstanceType": "cr2_instance_type"
                }
            ],
            "TotalTargetCapacity": "total_target_capacity",
            "TotalFulfilledCapacity": "total_target_capacity",
            "CreateTime": "yyyy-mm-ddThh:mm:ss.000Z",
            "AllocationStrategy": "prioritized"
        }
    ]
}
```

Example

```
C:\> aws ec2 describe-capacity-reservation-fleets \
--capacity-reservation-fleet-ids crf-abcdef01234567890
```

Example output

```
{
    "CapacityReservationFleets": [
        {
            "Status": "active",
            "EndDate": "2021-12-31T23:59:59.000Z",
            "InstanceMatchCriteria": "open",
            "Tags": []
        }
    ]
}
```

```
"Tags": [],
"CapacityReservationFleetId": "crf-abcdef01234567890",
"Tenancy": "default",
"InstanceTypeSpecifications": [
    {
        "CapacityReservationId": "cr-1234567890abcdef0",
        "AvailabilityZone": "us-east-1a",
        "FulfilledCapacity": 5.0,
        "Weight": 1.0,
        "CreateDate": "2021-07-02T08:34:33.398Z",
        "InstancePlatform": "Linux/UNIX",
        "TotalInstanceCount": 5,
        "Priority": 1,
        "EbsOptimized": true,
        "InstanceType": "m5.xlarge"
    }
],
"TotalTargetCapacity": 5,

"CreateTime": "2021-07-02T08:34:33.397Z",
"AllocationStrategy": "prioritized"
}
]
```

Modify a Capacity Reservation Fleet

You can modify the total target capacity and date of a Capacity Reservation Fleet at any time. When you modify the total target capacity of a Capacity Reservation Fleet, the Fleet automatically creates new Capacity Reservations, or modifies or cancels existing Capacity Reservations in the Fleet to meet the new total target capacity. When you modify the end date for the Fleet, the end dates for all of the individual Capacity Reservations are updated accordingly.

After you modify a Fleet, its status transitions to modifying. You can't attempt additional modifications to a Fleet while it is in the modifying state.

You can't modify the tenancy, Availability Zone, instance types, instance platforms, priorities, or weights used by a Capacity Reservation Fleet. If you need to change any of these parameters, you might need to cancel the existing Fleet and create a new one with the required parameters.

You can modify a Capacity Reservation Fleet using the command line only.

To modify a Capacity Reservation Fleet

Use the [modify-capacity-reservation-fleet](#) AWS CLI command.

Note

You can't specify --end-date and --remove-end-date in the same command.

```
C:\> aws ec2 modify-capacity-reservation-fleet \
--capacity-reservation-fleet-id cr_fleet_ids \
--total-target-capacity capacity_units \
--end-date yyyy-mm-ddThh:mm:ss.000Z \
--remove-end-date
```

Expected output

```
{
    "Return": true
}
```

Example: Modify total target capacity

```
C:\> aws ec2 modify-capacity-reservation-fleet \
--capacity-reservation-fleet-id crf-01234567890abcdef \
--total-target-capacity 160
```

Example: Modify end date

```
C:\> aws ec2 modify-capacity-reservation-fleet \
--capacity-reservation-fleet-id crf-01234567890abcdef \
--end-date 2021-07-04T23:59:59.000Z
```

Example: Remove end date

```
C:\> aws ec2 modify-capacity-reservation-fleet \
--capacity-reservation-fleet-id crf-01234567890abcdef \
--remove-end-date
```

Example output

```
{  
    "Return": true  
}
```

Cancel a Capacity Reservation Fleet

When you no longer need a Capacity Reservation Fleet and the capacity it reserves, you can cancel it. When you cancel a Fleet, its status changes to cancelled and it can no longer create new Capacity Reservations. Additionally, all of the individual Capacity Reservations in the Fleet are cancelled and the instances that were previously running in the reserved capacity continue to run normally in shared capacity.

You can cancel a Capacity Reservation Fleet using the command line only.

To cancel a Capacity Reservation Fleet

Use the [cancel-capacity-reservation-fleet](#) AWS CLI command.

```
C:\> aws ec2 cancel-capacity-reservation-fleets \
--capacity-reservation-fleet-ids cr_fleet_ids
```

Expected output

```
{  
    "SuccessfulFleetCancellations": [  
        {  
            "CurrentFleetState": "state",  
            "PreviousFleetState": "state",  
            "CapacityReservationFleetId": "cr_fleet_id_1"  
        },  
        {  
            "CurrentFleetState": "state",  
            "PreviousFleetState": "state",  
            "CapacityReservationFleetId": "cr_fleet_id_2"  
        }  
    ],  
    "FailedFleetCancellations": [  
        {  
            "CapacityReservationFleetId": "cr_fleet_id_3",  
            "CancelCapacityReservationFleetError": [  
                {  
                    "Code": "error_code",  
                    "Message": "error_message"  
                }  
            ]  
        }  
    ]  
}
```

```
{  
    "Code": "code",  
    "Message": "message"  
}  
]  
}  
]
```

Example: Successful cancellation

```
C:\> aws ec2 cancel-capacity-reservation-fleets \  
--capacity-reservation-fleet-ids crf-abcdef01234567890
```

Example output

```
{  
    "SuccessfulFleetCancellations": [  
        {  
            "CurrentFleetState": "cancelling",  
            "PreviousFleetState": "active",  
            "CapacityReservationFleetId": "crf-abcdef01234567890"  
        }  
    ],  
    "FailedFleetCancellations": []  
}
```

Example Capacity Reservation Fleet configurations

Topics

- [Example 1: Reserve capacity based on vCPUs \(p. 538\)](#)

Example 1: Reserve capacity based on vCPUs

The following example creates a Capacity Reservation Fleet that uses two instance types: m5.4xlarge and m5.12xlarge.

It uses a weighting system based on the number of vCPUs provided by the specified instance types. The total target capacity is 480 vCPUs. The m5.4xlarge provides 16 vCPUs and gets a weight of 16, while the m5.12xlarge provides 48 vCPUs and gets a weight of 48. This weighting system configures the Capacity Reservation Fleet to reserve capacity for either 30 m5.4xlarge instances ($480/16=30$), or 10 m5.12xlarge instances ($480/48=10$).

The Fleet is configured to prioritize the m5.12xlarge capacity and gets priority of 1, while the m5.4xlarge gets a lower priority of 2. This means that the fleet will attempt to reserve the m5.12xlarge capacity first, and only attempt to reserve the m5.4xlarge capacity if Amazon EC2 has insufficient m5.12xlarge capacity.

The Fleet reserves the capacity for Windows instances and the reservation automatically expires on October 31, 2021 at 23:59:59 UTC.

```
C:\> aws ec2 create-capacity-reservation-fleet \  
--total-target-capacity 48 \  
--allocation-strategy prioritized \  
--instance-match-criteria open \  
--tenancy default \  
--end-date 2021-10-31T23:59:59.000Z \  
--instance-type-specifications file://instanceTypeSpecification.json
```

The following is the contents of `instanceTypeSpecification.json`.

```
[  
  {  
    "InstanceType": "m5.4xlarge",  
    "InstancePlatform": "Windows",  
    "Weight": 16,  
    "AvailabilityZone": "us-east-1a",  
    "EbsOptimized": true,  
    "Priority": 2  
  },  
  {  
    "InstanceType": "m5.12xlarge",  
    "InstancePlatform": "Windows",  
    "Weight": 48,  
    "AvailabilityZone": "us-east-1a",  
    "EbsOptimized": true,  
    "Priority": 1  
  }]
```

Using service-linked roles for Capacity Reservation Fleet

On-Demand Capacity Reservation Fleet uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Capacity Reservation Fleet. Service-linked roles are predefined by Capacity Reservation Fleet and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Capacity Reservation Fleet easier because you don't have to manually add the necessary permissions. Capacity Reservation Fleet defines the permissions of its service-linked roles, and unless defined otherwise, only Capacity Reservation Fleet can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting their related resources. This protects your Capacity Reservation Fleet resources because you can't inadvertently remove permission to access the resources.

Service-linked role permissions for Capacity Reservation Fleet

Capacity Reservation Fleet uses the service-linked role named **AWSServiceRoleForEC2CapacityReservationFleet** to create, describe, modify, and cancel Capacity Reservations that were previously created by a Capacity Reservation Fleet, on your behalf.

The `AWSServiceRoleForEC2CapacityReservationFleet` service-linked role trusts the following entity to assume the role: `capacity-reservation-fleet.amazonaws.com`.

The role uses the **AWSEC2CapacityReservationFleetRolePolicy** policy, which includes the following permissions:

```
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": [  
        "ec2:DescribeCapacityReservations",  
        "ec2:DescribeInstances"  
      ],  
      "Resource": "*"  
    },
```

```
{  
    "Effect": "Allow",  
    "Action": [  
        "ec2:CreateCapacityReservation",  
        "ec2:CancelCapacityReservation",  
        "ec2:ModifyCapacityReservation"  
    ],  
    "Resource": [  
        "arn:aws:ec2:*::capacity-reservation/*"  
    ],  
    "Condition": {  
        "StringLike": {  
            "ec2:CapacityReservationFleet": "arn:aws:ec2:*::capacity-reservation-fleet/crf-*"  
        }  
    }  
},  
{  
    "Effect": "Allow",  
    "Action": [  
        "ec2:CreateTags"  
    ],  
    "Resource": [  
        "arn:aws:ec2:*::capacity-reservation/*"  
    ],  
    "Condition": {  
        "StringEquals": {  
            "ec2:CreateAction": "CreateCapacityReservation"  
        }  
    }  
}  
]  
}
```

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see [Service-Linked Role Permissions](#) in the *IAM User Guide*.

Create a service-linked role for Capacity Reservation Fleet

You don't need to manually create a service-linked role. When you create a Capacity Reservation Fleet using the `create-capacity-reservation-fleet` AWS CLI command or the `CreateCapacityReservationFleet` API, the service-linked role is automatically created for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a Capacity Reservation Fleet, Capacity Reservation Fleet creates the service-linked role for you again.

Edit a service-linked role for Capacity Reservation Fleet

Capacity Reservation Fleet does not allow you to edit the `AWSServiceRoleForEC2CapacityReservationFleet` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a Service-Linked Role](#) in the *IAM User Guide*.

Delete a service-linked role for Capacity Reservation Fleet

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete the resources for your service-linked role before you can manually delete it.

Note

If the Capacity Reservation Fleet service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete the AWSServiceRoleForEC2CapacityReservationFleet service-linked role

1. Use the `delete-capacity-reservation-fleet` AWS CLI command or the `DeleteCapacityReservationFleet` API to delete the Capacity Reservation Fleets in your account.
2. Use the IAM console, the AWS CLI, or the AWS API to delete the `AWSServiceRoleForEC2CapacityReservationFleet` service-linked role. For more information, see [Deleting a Service-Linked Role](#) in the *IAM User Guide*.

Supported Regions for Capacity Reservation Fleet service-linked roles

Capacity Reservation Fleet supports using service-linked roles in all of the Regions where the service is available. For more information, see [AWS Regions and Endpoints](#).

Monitoring Capacity Reservations

You can use the following features to monitor your Capacity Reservations:

Topics

- [Monitor Capacity Reservations using CloudWatch metrics \(p. 541\)](#)
- [Monitor Capacity Reservations using EventBridge \(p. 542\)](#)
- [Utilization notifications \(p. 545\)](#)

Monitor Capacity Reservations using CloudWatch metrics

With CloudWatch metrics, you can efficiently monitor your Capacity Reservations and identify unused capacity by setting CloudWatch alarms to notify you when usage thresholds are met. This can help you maintain a constant Capacity Reservation volume and achieve a higher level of utilization.

On-Demand Capacity Reservations send metric data to CloudWatch every five minutes. Metrics are not supported for Capacity Reservations that are active for less than five minutes.

For more information about viewing metrics in the CloudWatch console, see [Using Amazon CloudWatch Metrics](#). For more information about creating alarms, see [Creating Amazon CloudWatch Alarms](#).

Contents

- [Capacity Reservation usage metrics \(p. 541\)](#)
- [Capacity Reservation metric dimensions \(p. 542\)](#)
- [View CloudWatch metrics for Capacity Reservations \(p. 542\)](#)

Capacity Reservation usage metrics

The AWS/EC2CapacityReservations namespace includes the following usage metrics you can use to monitor and maintain on-demand capacity within thresholds you specify for your reservation.

Metric	Description
UsedInstanceCount	The number of instances that are currently in use. Unit: Count

Metric	Description
AvailableInstanceCount	The number of instances that are available. Unit: Count
TotalInstanceCount	The total number of instances you have reserved. Unit: Count
InstanceUtilization	The percentage of reserved capacity instances that are currently in use. Unit: Percent

Capacity Reservation metric dimensions

You can use the following dimensions to refine the metrics listed in the previous table.

Dimension	Description
CapacityReservationId	This globally unique dimension filters the data you request for the identified capacity reservation only.

View CloudWatch metrics for Capacity Reservations

Metrics are grouped first by the service namespace, and then by the supported dimensions. You can use the following procedures to view the metrics for your Capacity Reservations.

To view Capacity Reservation metrics using the CloudWatch console

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. If necessary, change the Region. From the navigation bar, select the Region where your Capacity Reservation resides. For more information, see [Regions and Endpoints](#).
3. In the navigation pane, choose **Metrics**.
4. For **All metrics**, choose **EC2 Capacity Reservations**.
5. Choose the metric dimension **By Capacity Reservation**. Metrics will be grouped by CapacityReservationId.
6. To sort the metrics, use the column heading. To graph a metric, select the check box next to the metric.

To view Capacity Reservation metrics (AWS CLI)

Use the following [list-metrics](#) command:

```
aws cloudwatch list-metrics --namespace "AWS/EC2CapacityReservations"
```

Monitor Capacity Reservations using EventBridge

AWS Health sends events to Amazon EventBridge when a Capacity Reservation in your account is below 20 percent usage over certain periods. With EventBridge, you can establish rules that trigger programmatic actions in response to such events. For example, you can create a rule that automatically cancels a Capacity Reservation when its utilization drops below 20 percent utilization over a 7-day period.

Events in EventBridge are represented as JSON objects. The fields that are unique to the event are contained in the "detail" section of the JSON object. The "event" field contains the event name. The "result" field contains the completed status of the action that triggered the event. For more information, see [Amazon EventBridge event patterns](#) in the *Amazon EventBridge User Guide*.

For more information, see the [Amazon EventBridge User Guide](#).

This feature is not supported in AWS GovCloud (US).

Contents

- [Events \(p. 543\)](#)
- [Create an EventBridge rule \(p. 544\)](#)

Events

AWS Health sends the following events when capacity usage for a Capacity Reservation is below 20 percent.

Events

- [AWS_EC2_ODCR_UNDERUTILIZATION_NOTIFICATION \(p. 543\)](#)
- [AWS_EC2_ODCR_UNDERUTILIZATION_NOTIFICATION_SUMMARY \(p. 544\)](#)

AWS_EC2_ODCR_UNDERUTILIZATION_NOTIFICATION

The following is an example of an event that is generated when a newly created Capacity Reservation is below 20 percent capacity usage over a 24-hour period.

```
{  
    "version": "0",  
    "id": "b3e00086-f271-12a1-a36c-55e8ddaa130a",

Create an EventBridge rule

To receive email notifications when your Capacity Reservation utilization drops below 20 percent, create an Amazon SNS topic, and then create an EventBridge rule for the AWS_EC2_ODCR_UNDERUTILIZATION_NOTIFICATION event.

To create the Amazon SNS topic

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation pane, choose **Topics**, and then choose **Create topic**.
3. For **Type**, choose **Standard**.
4. For **Name**, enter a name for the new topic.
5. Choose **Create topic**.
6. Choose **Create subscription**.

7. For **Protocol**, choose **Email**, and then for **Endpoint**, enter the email address that receives the notifications.
8. Choose **Create subscription**.
9. The email address entered above will receive email message with the following subject line: **AWS Notification - Subscription Confirmation**. Follow the directions to confirm your subscription.

To create the EventBridge rule

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. In the navigation pane, choose **Rules**, and then choose **Create rule**.
3. For **Name**, enter a name for the new rule.
4. For **Rule type**, choose **Rule with an event pattern**.
5. Choose **Next**.
6. In the **Event pattern**, do the following:
 - a. For **Event source**, choose **AWS services**.
 - b. For **AWS service**, choose **AWS Health**.
 - c. For **Event type**, choose **EC2 ODCR Underutilization Notification**.
7. Choose **Next**.
8. For **Target 1**, do the following:
 - a. For **Target types**, choose **AWS service**.
 - b. For **Select a target**, choose **SNS topic**.
 - c. For **Topic**, choose the topic that you created earlier.
9. Choose **Next** and then **Next** again.
10. Choose **Create rule**.

Utilization notifications

AWS Health sends the following email and AWS Health Dashboard notifications when capacity utilization for Capacity Reservations in your account drops below 20 percent.

- Individual notifications for each newly created Capacity Reservation that has been below 20 percent utilization over the last 24-hour period.
- A summary notification for all Capacity Reservations that have been below 20 percent utilization over the last 7-day period.

The email notifications and AWS Health Dashboard notifications are sent to the email address associated with the AWS account that owns the Capacity Reservations. The notifications include the following information:

- The ID of the Capacity Reservation.
- The Availability Zone of the Capacity Reservation.
- The average utilization rate for the Capacity Reservation.
- The instance type and platform (operating system) of the Capacity Reservation.

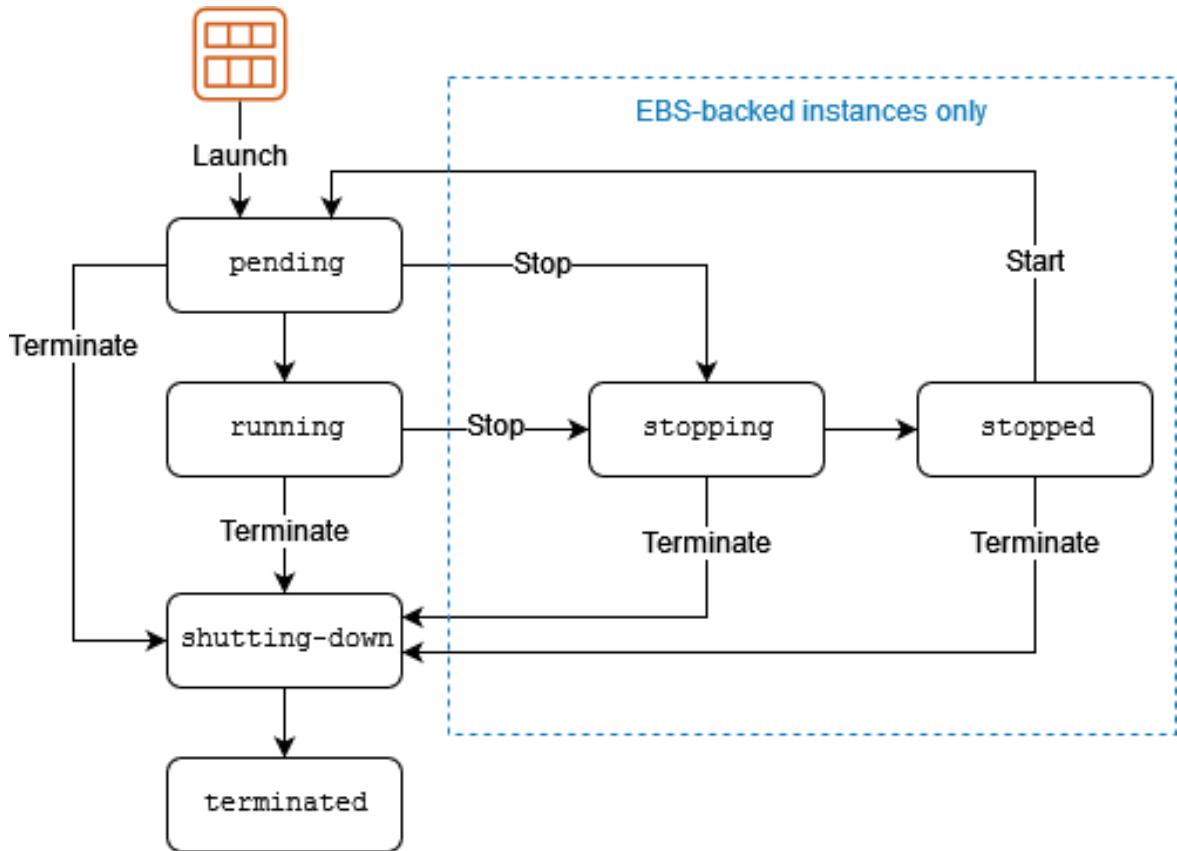

Additionally, when capacity utilization for a Capacity Reservation in your account drops below 20 percent over a 24-hour and 7-day period, AWS Health sends events to EventBridge. With EventBridge, you can create rules that activate automatic actions, such as sending email notifications or triggering AWS

Lambda functions, in response to such events. For more information, see [Monitor Capacity Reservations using EventBridge \(p. 542\)](#).

Instance lifecycle

An Amazon EC2 instance transitions through different states from the moment you launch it through to its termination.

The following illustration represents the transitions between instance states.

The following table provides a brief description of each instance state and indicates whether it is billed.

Note

The table indicates billing for instance usage only. Some AWS resources, such as Amazon EBS volumes and Elastic IP addresses, incur charges regardless of the instance's state. For more information, see [Avoiding Unexpected Charges](#) in the [AWS Billing User Guide](#).

Instance state	Description	Instance usage billing
pending	The instance is preparing to enter the running state. An instance enters the pending state when it is launched or when it is started after being in the stopped state.	Not billed

Instance state	Description	Instance usage billing
running	The instance is running and ready for use.	Billed
stopping	The instance is preparing to be stopped.	Not billed
stopped	The instance is shut down and cannot be used. The instance can be started at any time.	Not billed
shutting down	The instance is preparing to be terminated.	Not billed
terminated	The instance has been permanently deleted and cannot be started.	<p>Not billed</p> <p>Note Reserved Instances that applied to terminated instances are billed until the end of their term according to their payment option. For more information, see Reserved Instances (p. 353)</p>

Note

Rebooting an instance doesn't start a new instance billing period because the instance stays in the `running` state.

Instance launch

When you launch an instance, it enters the pending state. The instance type that you specified at launch determines the hardware of the host computer for your instance. We use the Amazon Machine Image (AMI) you specified at launch to boot the instance. After the instance is ready for you, it enters the `running` state. You can connect to your running instance and use it the way that you'd use a computer sitting in front of you.

As soon as your instance transitions to the `running` state, you're billed for each second, with a one-minute minimum, that you keep the instance running, even if the instance remains idle and you don't connect to it.

For more information, see [Launch your instance \(p. 551\)](#) and [Connect to your Windows instance \(p. 626\)](#).

Instance stop and start (Amazon EBS-backed instances only)

If your instance fails a status check or is not running your applications as expected, and if the root volume of your instance is an Amazon EBS volume, you can stop and start your instance to try to fix the problem.

When you stop your instance, it enters the stopping state, and then the stopped state. You are not charged for usage or data transfer fees for your instance when it is stopped. Charges are incurred for the storage of any Amazon EBS volumes. While your instance is in the stopped state, you can modify certain attributes of the instance, including the instance type.

When you start your instance, it enters the pending state, and the instance is moved to a new host computer (though in some cases, it remains on the current host). When you stop and start your instance, you lose any data on the instance store volumes attached to the previous host computer.

Your instance retains its private IPv4 address, which means that an Elastic IP address associated with the private IPv4 address or network interface remains associated with your instance. If your instance has an IPv6 address, it retains the IPv6 address.

Each time you transition an instance from stopped to `running`, you are charged per second when the instance is running, with a minimum of one minute per instance start.

For more details about stopping and starting an instance, see [Stop and start your instance \(p. 594\)](#).

Instance hibernate (Amazon EBS-backed instances only)

When you hibernate an instance, we signal the operating system to perform hibernation (suspend-to-disk), which saves the contents from the instance memory (RAM) to your Amazon EBS root volume. We persist the instance's Amazon EBS root volume and any attached Amazon EBS data volumes. When you start your instance, the Amazon EBS root volume is restored to its previous state and the RAM contents are reloaded. Previously attached data volumes are reattached and the instance retains its instance ID.

When you hibernate your instance, it enters the stopping state, and then the stopped state. We don't charge usage for a hibernated instance when it is in the stopped state, but we do charge while it is in the stopping state, unlike when you [stop an instance \(p. 548\)](#) without hibernating it. We don't charge usage for data transfer fees, but we do charge for the storage for any Amazon EBS volumes, including storage for the RAM data.

When you start your hibernated instance, it enters the pending state, and we move the instance to a new host computer (though in some cases, it remains on the current host).

Your instance retains its private IPv4 address, which means that an Elastic IP address associated with the private IPv4 address or network interface is still associated with your instance. If your instance has an IPv6 address, it retains its IPv6 address.

For more information, see [Hibernate your On-Demand Windows instance \(p. 602\)](#).

Instance reboot

You can reboot your instance using the Amazon EC2 console, a command line tool, and the Amazon EC2 API. We recommend that you use Amazon EC2 to reboot your instance instead of running the operating system reboot command from your instance.

Rebooting an instance is equivalent to rebooting an operating system. The instance remains on the same host computer and maintains its public DNS name, private IP address, and any data on its instance store volumes. It typically takes a few minutes for the reboot to complete, but the time it takes to reboot depends on the instance configuration.

Rebooting an instance doesn't start a new instance billing period; per second billing continues without a further one-minute minimum charge.

For more information, see [Reboot your instance \(p. 612\)](#).

Instance retirement

An instance is scheduled to be retired when AWS detects the irreparable failure of the underlying hardware hosting the instance. When an instance reaches its scheduled retirement date, it is stopped or terminated by AWS. If your instance root device is an Amazon EBS volume, the instance is stopped, and you can start it again at any time. If your instance root device is an instance store volume, the instance is terminated, and cannot be used again.

For more information, see [Instance retirement \(p. 613\)](#).

Instance termination

When you've decided that you no longer need an instance, you can terminate it. As soon as the status of an instance changes to shutting-down or terminated, you stop incurring charges for that instance.

If you enable termination protection, you can't terminate the instance using the console, CLI, or API.

After you terminate an instance, it remains visible in the console for a short while, and then the entry is automatically deleted. You can also describe a terminated instance using the CLI and API. Resources (such as tags) are gradually disassociated from the terminated instance, therefore may no longer be visible on the terminated instance after a short while. You can't connect to or recover a terminated instance.

Each Amazon EBS-backed instance supports the `InstanceInitiatedShutdownBehavior` attribute, which controls whether the instance stops or terminates when you initiate shutdown from within the instance itself. The default behavior is to stop the instance. You can modify the setting of this attribute while the instance is running or stopped.

Each Amazon EBS volume supports the `DeleteOnTermination` attribute, which controls whether the volume is deleted or preserved when you terminate the instance it is attached to. The default is to delete the root device volume and preserve any other EBS volumes.

For more information, see [Terminate your instance \(p. 615\)](#).

Differences between reboot, stop, hibernate, and terminate

The following table summarizes the key differences between rebooting, stopping, hibernating, and terminating your instance.

Characteristic	Reboot	Stop/start (Amazon EBS-backed instances only)	Hibernate (Amazon EBS-backed instances only)	Terminate
Host computer	The instance stays on the same host computer	We move the instance to a new host computer (though in some cases, it remains on the current host).	We move the instance to a new host computer (though in some cases, it remains on the current host).	None
Private and public IPv4 addresses	These addresses stay the same	The instance keeps its private IPv4 address. The instance gets a new public IPv4 address, unless it has an Elastic IP address, which doesn't change during a stop/start.	The instance keeps its private IPv4 address. The instance gets a new public IPv4 address, unless it has an Elastic IP address, which doesn't change during a stop/start.	None
Elastic IP addresses (IPv4)	The Elastic IP address remains associated with the instance	The Elastic IP address remains associated with the instance	The Elastic IP address remains associated with the instance	The Elastic IP address is disassociated from the instance
IPv6 address	The address stays the same	The instance keeps its IPv6 address	The instance keeps its IPv6 address	None
Instance store volumes	The data is preserved	The data is erased	The data is erased	The data is erased
Root device volume	The volume is preserved	The volume is preserved	The volume is preserved	The volume is deleted by default
RAM (contents of memory)	The RAM is erased	The RAM is erased	The RAM is saved to a file on the root volume	The RAM is erased
Billing	The instance billing hour doesn't change.	You stop incurring charges for an instance as soon as its state changes to stopping. Each time an instance transitions from stopped to running, we start a new instance billing period, billing a minimum of one minute every time you start your instance.	You incur charges while the instance is in the stopping state, but stop incurring charges when the instance is in the stopped state. Each time an instance transitions from stopped to running, we start a new instance billing period, billing a minimum of one minute every time you start your instance.	You stop incurring charges for an instance as soon as its state changes to shutting-down.

Operating system shutdown commands always terminate an instance store-backed instance. You can control whether operating system shutdown commands stop or terminate an Amazon EBS-backed instance. For more information, see [Change the instance initiated shutdown behavior \(p. 619\)](#).

Launch your instance

An instance is a virtual server in the AWS Cloud. You launch an instance from an Amazon Machine Image (AMI). The AMI provides the operating system, application server, and applications for your instance.

When you sign up for AWS, you can get started with Amazon EC2 for free using the [AWS Free Tier](#). You can use the free tier to launch and use a t2.micro instance for free for 12 months (in Regions where t2.micro is unavailable, you can use a t3.micro instance under the free tier). If you launch an instance that is not within the free tier, you incur the standard Amazon EC2 usage fees for the instance. For more information, see [Amazon EC2 pricing](#).

You can launch an instance using the following methods.

Method	Documentation
[Amazon EC2 console] Use the launch instance wizard to specify the launch parameters.	Launch an instance using the old launch instance wizard (p. 561)
[Amazon EC2 console] Create a launch template and launch the instance from the launch template.	Launch an instance from a launch template (p. 567)
[Amazon EC2 console] Use an existing instance as the base.	Launch an instance using parameters from an existing instance (p. 591)
[Amazon EC2 console] Use an AMI that you purchased from the AWS Marketplace.	Launch an AWS Marketplace instance (p. 592)
[AWS CLI] Use an AMI that you select.	Using Amazon EC2 through the AWS CLI
[AWS Tools for Windows PowerShell] Use an AMI that you select.	Amazon EC2 from the AWS Tools for Windows PowerShell
[AWS CLI] Use EC2 Fleet to provision capacity across different EC2 instance types and Availability Zones, and across On-Demand Instance, Reserved Instance, and Spot Instance purchase models.	EC2 Fleet (p. 962)
[AWS CloudFormation] Use a AWS CloudFormation template to specify an instance.	AWS::EC2::Instance in the AWS CloudFormation User Guide
[AWS SDK] Use a language-specific AWS SDK to launch an instance.	AWS SDK for .NET AWS SDK for C++ AWS SDK for Go AWS SDK for Java AWS SDK for JavaScript AWS SDK for PHP V3 AWS SDK for Python

Method	Documentation
	AWS SDK for Ruby V3

Note

To launch an EC2 instance into an IPv6-only subnet, you must use [Instances built on the Nitro System \(p. 218\)](#).

Note

When launching an IPv6-only instance, it is possible that DHCPv6 may not immediately provide the instance with the IPv6 DNS name server. During this initial delay, the instance may not be able to resolve public domains.

For instances running on Amazon Linux 2, if you want to immediately update the /etc/resolv.conf file with the IPv6 DNS name server, run the following [cloud-init directive](#) at launch:

```
#cloud-config
bootcmd:
- /usr/bin/sed -i -E 's,^nameserver\s+[\.\[[:digit:]\]]+\$,nameserver fd00:ec2::253,' /
etc/resolv.conf
```

Another option is to change the configuration file and re-image your AMI so that the file has the IPv6 DNS name server address immediately on booting.

When you launch your instance, you can launch your instance in a subnet that is associated with one of the following resources:

- An Availability Zone - This option is the default.
- A Local Zone - To launch an instance in a Local Zone, you must opt in to the Local Zone, and then create a subnet in the zone. For more information, see [Local Zones](#)
- A Wavelength Zone - To launch an instance in a Wavelength Zone, you must opt in to the Wavelength Zone, and then create a subnet in the zone. For information about how to launch an instance in a Wavelength Zone, see [Get started with AWS Wavelength](#) in the *AWS Wavelength Developer Guide*.
- An Outpost - To launch an instance in an Outpost, you must create an Outpost. For information about how to create an Outpost, see [Get Started with AWS Outposts](#) in the *AWS Outposts User Guide*.

After you launch your instance, you can connect to it and use it. To begin, the instance state is pending. When the instance state is running, the instance has started booting. There might be a short time before you can connect to the instance. Note that bare metal instance types might take longer to launch. For more information about bare metal instances, see [Instances built on the Nitro System \(p. 218\)](#).

The instance receives a public DNS name that you can use to contact the instance from the internet. The instance also receives a private DNS name that other instances within the same VPC can use to contact the instance. For more information about connecting to your instance, see [Connect to your Windows instance \(p. 626\)](#).

When you are finished with an instance, be sure to terminate it. For more information, see [Terminate your instance \(p. 615\)](#).

Launch an instance using the new launch instance wizard

You can launch an instance using the new launch instance wizard. The launch instance wizard specifies the launch parameters that are required for launching an instance. Where the launch instance wizard provides a default value, you can accept the default or specify your own value. If you accept the default values, then it's possible to launch an instance by selecting only a key pair.

Before you launch your instance, be sure that you are set up. For more information, see [Set up to use Amazon EC2 \(p. 7\)](#).

Important

When you launch an instance that's not within the [AWS Free Tier](#), you are charged for the time that the instance is running, even if it remains idle.

Topics

- [About the new launch instance wizard \(p. 553\)](#)
- [Quickly launch an instance \(p. 554\)](#)
- [Launch an instance using defined parameters \(p. 554\)](#)
- [Launch an instance using the old launch instance wizard \(p. 561\)](#)

About the new launch instance wizard

Welcome to the new and improved launch experience—a quicker and easier way to launch an instance.

We're in the process of rolling out the new launch instance wizard. If it's not available in your currently selected Region, you can select a different Region to check if it's available there.

Current improvements

- **Single page layout with summary side panel**

Quickly get up and running with our new one-page design. See all of your settings in one location. No need to navigate back and forth between steps to ensure your configuration is correct. Use the **Summary** panel for an overview and to easily navigate the page.

- **Improved AMI selector**

New users – Use the **Quick Start** Amazon Machine Image (AMI) selector to select an operating system so that you can quickly launch an instance.

Experienced users – The AMI selector displays your recently used AMIs and the AMIs that you own, making it easier to select the AMIs that you care about. You can still browse the full catalog to find new AMIs.

Work in progress

We're working continuously to improve the experience. Here's what we're currently working on:

- **Defaults and dependency assistance**
 - **Default values** will be provided for all fields.
 - **Additional logic** will be added to help you set up your instance configuration correctly (for example, we'll disable parameters that are not available with your current settings).
- **Further simplified designs**
 - **Simplified views and summaries** and a **more responsive design** will be added to make the one-page experience more scalable.
 - **Simplified networking** features will be added to help you to configure your firewall rules quickly and easily (for example, we'll select common preset rules).

There will be many more improvements to the launch experience in the months ahead.

Please send feedback

We'd appreciate your feedback on the new launch instance wizard. We'll use your feedback to continue improving the experience over the next few months. You can send us feedback directly from the EC2 console, or use the **Provide feedback** link at the bottom of this page.

Quickly launch an instance

To set up an instance quickly for testing purposes, follow these steps. You'll select the operating system and your key pair, and accept the default values. For information about all of the parameters in the launch instance wizard, see [Launch an instance using defined parameters \(p. 554\)](#).

To quickly launch an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). Select a Region in which to launch the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see [Resource locations \(p. 2075\)](#).
3. From the Amazon EC2 console dashboard, choose **Launch instance**.
4. (Optional) Under **Name and tags**, for **Name**, enter a descriptive name for your instance.
5. Under **Application and OS Images (Amazon Machine Image)**, choose **Quick Start**, and then choose the operating system (OS) for your instance.
6. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one.
7. In the **Summary** panel, choose **Launch instance**.

Launch an instance using defined parameters

Except for the key pair, the launch instance wizard provides default values for all of the parameters. You can accept any or all of the defaults, or configure an instance by specifying your own values for each parameter. The parameters are grouped in the launch instance wizard. The following instructions take you through each parameter group.

Parameters for instance configuration

- [Initiate instance launch \(p. 554\)](#)
- [Name and tags \(p. 554\)](#)
- [Application and OS Images \(Amazon Machine Image\) \(p. 555\)](#)
- [Instance type \(p. 556\)](#)
- [Key pair \(login\) \(p. 556\)](#)
- [Network settings \(p. 556\)](#)
- [Configure storage \(p. 558\)](#)
- [Advanced details \(p. 559\)](#)
- [Summary \(p. 561\)](#)

Initiate instance launch

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). Select a Region in which to launch the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see [Resource locations \(p. 2075\)](#).
3. From the Amazon EC2 console dashboard, choose **Launch instance**.

Name and tags

The instance name is a tag, where the key is **Name**, and the value is the name that you specify. You can tag the instance, volumes, elastic graphics, and network interfaces. For Spot Instances, you can tag the Spot Instance request only. For information about tags, see [Tag your Amazon EC2 resources \(p. 2085\)](#).

Specifying an instance name and additional tags is optional.

- For **Name**, enter a descriptive name for the instance. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.
- To add additional tags, choose **Add additional tags**. Choose **Add tag**, and then enter a key and value, and select the resource type to tag. Choose **Add tag** again for each additional tag to add.

Application and OS Images (Amazon Machine Image)

An Amazon Machine Image (AMI) contains the information required to create an instance. For example, an AMI might contain the software that's required to act as a web server, such as Windows, Apache, and your website.

You can find a suitable AMI as follows. With each option for finding an AMI, you can choose **Cancel** (at top right) to return to the launch instance wizard without choosing an AMI.

Search bar

To search through all available AMIs, enter a keyword in the AMI search bar and then press **Enter**. To select an AMI, choose **Select**.

Recents

The AMIs that you've recently used.

Choose **Recently launched** or **Currently in use**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

My AMIs

The private AMIs that you own, or private AMIs that have been shared with you.

Choose **Owned by me** or **Shared with me**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

Quick Start

AMIs are grouped by operating system (OS) to help you get started quickly.

First select the OS that you need, and then, from **Amazon Machine Image (AMI)**, select an AMI. To select an AMI that is eligible for the free tier, make sure that the AMI is marked **Free tier eligible**.

Browse more AMIs

Choose **Browse more AMIs** to browse the full AMI catalog.

- To search through all available AMIs, enter a keyword in the search bar and then press **Enter**.
- To find an AMI by using a Systems Manager parameter, choose the arrow button to the right of the search bar, and then choose **Search by Systems Manager parameter**. For more information, see [Use a Systems Manager parameter to find an AMI \(p. 126\)](#).
- To search by category, choose **Quickstart AMIs**, **My AMIs**, **AWS Marketplace AMIs**, or **Community AMIs**.

The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see [Launch an AWS Marketplace instance \(p. 592\)](#). In **Community AMIs**, you can find AMIs that AWS community members have made available for others to use. AMIs from Amazon or a verified partner are marked **Verified provider**.

- To filter the list of AMIs, select one or more check boxes under **Refine results** on the left of the screen. The filter options are different depending on the selected search category.

- Check the **Virtualization** type listed for each AMI. Notice which AMIs are the type that you need: either **hvm** or **paravirtual**. For example, some instance types require HVM.
- Check the **Boot mode** listed for each AMI. Notice which AMIs use the boot mode that you need: either **legacy-bios**, **uefi**, or **uefi-preferred**. For more information, see [Boot modes \(p. 28\)](#).
- Choose an AMI that meets your needs, and then choose **Select**.

Warning when changing the AMI

If you modify the configuration of any volumes or security groups associated with the selected AMI, and then you choose a different AMI, a window opens to warn you that some of your current settings will be changed or removed. You can review the changes to the security groups and volumes. Furthermore, you can either view which volumes will be added and deleted, or view only the volumes that will be added.

Instance type

The instance type defines the hardware configuration and size of the instance. Larger instance types have more CPU and memory. For more information, see [Instance types](#).

- For **Instance type**, select the instance type for the instance.

Free Tier – If your AWS account is less than 12 months old, you can use Amazon EC2 under the Free Tier by selecting the **t2.micro** instance type (or the **t3.micro** instance type in Regions where **t2.micro** is unavailable). If an instance type is eligible under the Free Tier, it is labeled **Free tier eligible**. For more information about t2.micro and t3.micro, see [Burstable performance instances \(p. 245\)](#).

- **Compare instance types:** You can compare different instance types by the following attributes: number of vCPUs, architecture, amount of memory (GiB), amount of storage (GB), storage type, and network performance.

Key pair (login)

For **Key pair name**, choose an existing key pair, or choose **Create new key pair** to create a new one. For more information, see [Amazon EC2 key pairs and Windows instances \(p. 1662\)](#).

Important

If you choose the **Proceed without key pair (Not recommended)** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

Network settings

Configure the network settings, as necessary.

- **VPC:** Choose an existing VPC for your instance. You can choose the default VPC or a VPC that you created. For more information, see [the section called "Virtual private clouds" \(p. 1373\)](#).
- **Subnet:** You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone, or Outpost.

To launch the instance in an Availability Zone, select the subnet in which to launch your instance. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the launch instance wizard and choose the Refresh icon to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with the Outpost.

- **Auto-assign Public IP:** Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address, and instances in a nondefault subnet don't.

You can select **Enable** or **Disable** to override the subnet's default setting. For more information, see [Public IPv4 addresses \(p. 1236\)](#).

- **Firewall (security groups):** Use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. For more information about security groups, see [Amazon EC2 security groups for Windows instances \(p. 1674\)](#).

If you add a network interface, you must specify the same security group in the network interface.

Select or create a security group as follows:

- To select an existing security group for your VPC, choose **Select existing security group**, and select your security group from **Common security groups**.
- To create a new security group for your VPC, choose **Create security group**. The launch instance wizard automatically defines the **launch-wizard-x** security group and provides the following check boxes for quickly adding security group rules:

Allow SSH traffic from – Creates an inbound rule to allow you to connect to your instance over RDP (port 3389). Specify whether the traffic comes from **Anywhere**, **Custom**, or **My IP**.

Allow HTTPS traffic from the internet – Creates an inbound rule that opens port 443 (HTTPS) to allow internet traffic from anywhere. If your instance will be a web server, you'll need this rule.

Allow HTTP traffic from the internet – Creates an inbound rule that opens port 80 (HTTP) to allow internet traffic from anywhere. If your instance will be a web server, you'll need this rule.

You can edit these rules and add rules to suit your needs.

To edit or add a rule, choose **Edit** (at top right). To add a rule, choose **Add security group rule**. For **Type**, select the network traffic type. The **Protocol** field is automatically filled in with the protocol to open to network traffic. For **Source type**, select the source type. To let the launch instance wizard add your computer's public IP address, choose **My IP**. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

Warning

Rules that enable all IP addresses (`0.0.0.0/0`) to access your instance over SSH or RDP are acceptable if you are briefly launching a test instance and will stop or terminate it soon, but are unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

- **Advanced network configuration** – Available only if you choose a subnet.

Network interface

- **Device index:** The index of the network card. The primary network interface must be assigned to network card index **0**. Some instance types support multiple network cards.
- **Network interface:** Select **New interface** to let Amazon EC2 create a new interface, or select an existing, available network interface.
- **Description:** (Optional) A description for the new network interface.
- **Subnet:** The subnet in which to create the new network interface. For the primary network interface (`eth0`), this is the subnet in which the instance is launched. If you've entered an existing network interface for `eth0`, the instance is launched in the subnet in which the network interface is located.
- **Security groups:** One or more security groups in your VPC with which to associate the network interface.
- **Primary IP:** A private IPv4 address from the range of your subnet. Leave blank to let Amazon EC2 choose a private IPv4 address for you.
- **Secondary IP:** One or more additional private IPv4 addresses from the range of your subnet. Choose **Manually assign** and enter an IP address. Choose **Add IP** to add another IP address. Alternatively,

choose **Automatically assign** to let Amazon EC2 choose one for you, and enter a value to indicate the number of IP addresses to add.

- (**IPv6-only**) **IPv6 IPs**: An IPv6 address from the range of the subnet. Choose **Manually assign** and enter an IP address. Choose **Add IP** to add another IP address. Alternatively, choose **Automatically assign** to let Amazon EC2 choose one for you, and enter a value to indicate the number of IP addresses to add.
- **IPv4 Prefixes**: The IPv4 prefixes for the network interface.
- **IPv6 Prefixes**: The IPv6 prefixes for the network interface.
- (**Dual-stack and IPv6-only**) **Assign Primary IPv6 IP**: (Optional) If you're launching an instance into a dual-stack or IPv6-only subnet, you have the option to **Assign Primary IPv6 IP**. Assigning a primary IPv6 address enables you to avoid disrupting traffic to instances or ENIs. Choose **Enable** if this instance relies on its IPv6 address not changing. When you launch the instance, AWS will automatically assign an IPv6 address associated with the ENI attached to your instance to be the primary IPv6 address. Once you enable an IPv6 GUA address to be a primary IPv6, you cannot disable it. When you enable an IPv6 GUA address to be a primary IPv6, the first IPv6 GUA will be made the primary IPv6 address until the instance is terminated or the network interface is detached. If you have multiple IPv6 addresses associated with an ENI attached to your instance and you enable a primary IPv6 address, the first IPv6 GUA address associated with the ENI becomes the primary IPv6 address.
- **Delete on termination**: Whether the network interface is deleted when the instance is deleted.
- **Elastic Fabric Adapter**: Indicates whether the network interface is an Elastic Fabric Adapter. For more information, see [Elastic Fabric Adapter](#).

Choose **Add network interface** to add a secondary network interface. A secondary network interface can reside in a different subnet of the VPC, provided it's in the same Availability Zone as your instance.

For more information, see [Elastic network interfaces \(p. 1280\)](#). If you specify more than one network interface, your instance cannot receive a public IPv4 address. Additionally, if you specify an existing network interface for eth0, you cannot override the subnet's public IPv4 setting using **Auto-assign Public IP**. For more information, see [Assign a public IPv4 address during instance launch \(p. 1239\)](#).

Configure storage

The AMI you selected includes one or more volumes of storage, including the root volume. You can specify additional volumes to attach to the instance.

You can use the **Simple** or **Advanced** view. With the **Simple** view, you specify the size and type of the volume. To specify all volume parameters, choose the **Advanced** view (at top right of the card).

By using the **Advanced** view, you can configure each volume as follows:

- **Storage type**: Select Amazon EBS or instance store volumes to associate with your instance. The volume types available in the list depend on the instance type that you've chosen. For more information, see [Amazon EC2 instance store \(p. 1996\)](#) and [Amazon EBS volumes \(p. 1704\)](#).
- **Device name**: Select from the list of available device names for the volume.
- **Snapshot**: Select the snapshot from which to restore the volume. You can search for available shared and public snapshots by entering text into the **Snapshot** field.
- **Size (GiB)**: For EBS volumes, you can specify a storage size. If you have selected an AMI and instance that are eligible for the free tier, keep in mind that to stay within the free tier, you must stay under 30 GiB of total storage. For more information, see [Constraints on the size and configuration of an EBS volume \(p. 1724\)](#).
- **Volume type**: For EBS volumes, select a volume type. For more information, see [Amazon EBS volume types \(p. 1707\)](#).
- **IOPS**: If you have selected a Provisioned IOPS SSD volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support.

- **Delete on termination:** For Amazon EBS volumes, choose **Yes** to delete the volume when the instance is terminated, or choose **No** to keep the volume. For more information, see [Preserve Amazon EBS volumes on instance termination \(p. 620\)](#).
- **Encrypted:** If the instance type supports EBS encryption, you can choose **Yes** to enable encryption for the volume. If you have enabled encryption by default in this Region, encryption is enabled for you. For more information, see [Amazon EBS encryption \(p. 1921\)](#).
- **KMS key:** If you selected **Yes** for **Encrypted**, then you must select a customer managed key to use to encrypt the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or specify the ARN of any customer managed key that you created.
- **File systems:** Mount an Amazon EFS or Amazon FSx file system to the instance. For more information about mounting an Amazon EFS file system, see [Use Amazon EFS with Amazon EC2 \(p. 2015\)](#). For more information about mounting an Amazon FSx file system, see [Use Amazon FSx with Amazon EC2 \(p. 2015\)](#)

Advanced details

For **Advanced details**, expand the section to view the fields and specify any additional parameters for the instance.

- **Purchasing option:** Choose **Request Spot Instances** to request Spot Instances at the Spot price, capped at the On-Demand price, and choose **Customize** to change the default Spot Instance settings. You can set your maximum price (not recommended), and change the request type, request duration, and interruption behavior. If you do not request a Spot Instance, Amazon EC2 launches an On-Demand Instance by default. For more information, see [Create a Spot Instance request \(p. 407\)](#).
- **Domain join directory:** Select the AWS Directory Service directory (domain) to which your Windows instance is joined after launch. If you select a domain, you must select an IAM role with the required permissions. For more information, see [Seamlessly join a Windows EC2 instance](#).
- **IAM instance profile:** Select an AWS Identity and Access Management (IAM) instance profile to associate with the instance. For more information, see [IAM roles for Amazon EC2 \(p. 1649\)](#).
- **Hostname type:** Select whether the guest OS hostname of the instance will include the resource name or the IP name. For more information, see [Amazon EC2 instance hostname types \(p. 1250\)](#).
- **DNS Hostname:** Determines if the DNS queries to the resource name or the IP name (depending on what you selected for **Hostname type**) will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information, see [Amazon EC2 instance hostname types \(p. 1250\)](#).
- **Shutdown behavior:** Select whether the instance should stop or terminate when shut down. For more information, see [Change the instance initiated shutdown behavior \(p. 619\)](#).
- **Stop - Hibernate behavior:** To enable hibernation, choose **Enable**. This field is available only if your instance meets the hibernation prerequisites. For more information, see [Hibernate your On-Demand Windows instance \(p. 602\)](#).
- **Termination protection:** To prevent accidental termination, choose **Enable**. For more information, see [Enable termination protection \(p. 618\)](#).
- **Stop protection:** To prevent accidental stopping, choose **Enable**. For more information, see [Enable stop protection \(p. 599\)](#).
- **Detailed CloudWatch monitoring:** Choose **Enable** to turn on detailed monitoring of your instance using Amazon CloudWatch. Additional charges apply. For more information, see [Monitor your instances using CloudWatch \(p. 1183\)](#).
- **Elastic GPU:** Select an Elastic Graphics accelerator to attach to the instance. Not all instance types support Elastic Graphics. For more information, see [Amazon Elastic Graphics \(p. 1135\)](#).
- **Elastic inference:** An elastic inference accelerator to attach to your EC2 CPU instance. For more information, see [Working with Amazon Elastic Inference](#) in the *Amazon Elastic Inference Developer Guide*.

Note

Starting April 15, 2023, AWS will not onboard new customers to Amazon Elastic Inference (EI), and will help current customers migrate their workloads to options that offer better price and performance. After April 15, 2023, new customers will not be able to launch instances with Amazon EI accelerators in Amazon SageMaker, Amazon ECS, or Amazon EC2. However, customers who have used Amazon EI at least once during the past 30-day period are considered current customers and will be able to continue using the service.

- **Credit specification:** Choose **Unlimited** to enable applications to burst beyond the baseline for as long as needed. This field is only valid for **T** instances. Additional charges may apply. For more information, see [Burstable performance instances \(p. 245\)](#).
- **Placement group name:** Specify a placement group in which to launch the instance. You can select an existing placement group, or create a new one. Not all instance types support launching an instance in a placement group. For more information, see [Placement groups \(p. 1352\)](#).
- **EBS-optimized instance:** An instance that's optimized for Amazon EBS uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. If the instance type supports this feature, choose **Enable** to enable it. Additional charges apply. For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).
- **Capacity Reservation:** Specify whether to launch the instance into any open Capacity Reservation (**Open**), a specific Capacity Reservation (**Target by ID**), or a Capacity Reservation group (**Target by group**). To specify that a Capacity Reservation should not be used, choose **None**. For more information, see [Launch instances into an existing Capacity Reservation \(p. 510\)](#).
- **Tenancy:** Choose whether to run your instance on shared hardware (**Shared**), isolated, dedicated hardware (**Dedicated**), or on a Dedicated Host (**Dedicated host**). If you choose to launch the instance onto a Dedicated Host, you can specify whether to launch the instance into a host resource group or you can target a specific Dedicated Host. Additional charges may apply. For more information, see [Dedicated Instances \(p. 499\)](#) and [Dedicated Hosts \(p. 458\)](#).
- **RAM disk ID:** (Only valid for paravirtual (PV) AMIs) Select a RAM disk for the instance. If you have selected a kernel, you might need to select a specific RAM disk with the drivers to support it.
- **Kernel ID:** (Only valid for paravirtual (PV) AMIs) Select a kernel for the instance.
- **Nitro Enclave:** Allows you to create isolated execution environments, called enclaves, from Amazon EC2 instances. Select **Enable** to enable the instance for AWS Nitro Enclaves. For more information, see [What is AWS Nitro Enclaves?](#) in the *AWS Nitro Enclaves User Guide*.
- **License configurations:** You can launch instances against the specified license configuration to track your license usage. For more information, see [Create a license configuration](#) in the *AWS License Manager User Guide*.
- **Metadata accessible:** You can enable or disable access to the instance metadata. For more information, see [Configure instance metadata options for new instances \(p. 869\)](#).
- **Metadata transport:** Enable the instance to reach the link local IMDSv2 IPv6 address (fd00:ec2::254) to retrieve instance metadata. This option is only available if you are launching [Instances built on the Nitro System \(p. 218\)](#) into an [IPv6-only subnet](#). For more information about retrieving instance metadata, see [Retrieve instance metadata \(p. 876\)](#).
- **Metadata version:** If you enable access to the instance metadata, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances \(p. 869\)](#).
- **Metadata response hop limit:** If you enable instance metadata, you can set the allowable number of network hops for the metadata token. For more information, see [Configure instance metadata options for new instances \(p. 869\)](#).
- **Allow tags in metadata:** If you select **Enable**, the instance will allow access to all of its tags from its metadata. If no value is specified, then by default, access to the tags in instance metadata is not allowed. For more information, see [Allow access to tags in instance metadata \(p. 2097\)](#).
- **User data:** You can specify user data to configure an instance during launch, or to run a configuration script. For more information, see [Run commands on your Windows instance at launch \(p. 853\)](#).

Summary

Use the **Summary** panel to specify the number of instances to launch, to review your instance configuration, and to launch your instances.

- **Number of instances:** Enter the number of instances to launch. All of the instances will launch with the same configuration.

Tip

To ensure faster instance launches, break up large requests into smaller batches. For example, create five separate launch requests for 100 instances each instead of one launch request for 500 instances.

- (Optional) If you specify more than one instance, to help ensure that you maintain the correct number of instances to handle demand on your application, you can choose **consider EC2 Auto Scaling** to create a launch template and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).

Note

If Amazon EC2 Auto Scaling marks an instance that is in an Auto Scaling group as unhealthy, the instance is automatically scheduled for replacement where it is terminated and another is launched, and you lose your data on the original instance. An instance is marked as unhealthy if you stop or reboot the instance, or if another event marks the instance as unhealthy. For more information, see [Health checks for Auto Scaling instances](#) in the *Amazon EC2 Auto Scaling User Guide*.

- Review the details of your instance, and make any necessary changes. You can navigate directly to a section by choosing its link in the **Summary** panel.
- When you're ready to launch your instance, choose **Launch instance**.

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 2114\)](#).

(Optional) You can create a billing alert for the instance. On the confirmation screen, under **Next Steps**, choose **Create billing alerts** and follow the directions. Billing alerts can also be created after you launch the instance. For more information, see [Creating a billing alarm to monitor your estimated AWS charges](#) in the *Amazon CloudWatch User Guide*.

Launch an instance using the old launch instance wizard

Important

You can't use the old launch instance wizard in AWS Regions that support the new launch instance wizard. Each Region either supports the new launch experience or the old launch experience, but not both.

You can launch an instance using the old launch instance wizard only if your Region supports the old launch experience. The launch instance wizard specifies all the launch parameters required for launching an instance. Where the launch instance wizard provides a default value, you can accept the default or specify your own value. You must specify an AMI and a key pair to launch an instance.

For the instructions to use the new launch instance wizard, see [Launch an instance using the new launch instance wizard \(p. 552\)](#).

Before you launch your instance, be sure that you are set up. For more information, see [Set up to use Amazon EC2 \(p. 7\)](#).

Important

When you launch an instance that's not within the [AWS Free Tier](#), you are charged for the time that the instance is running, even if it remains idle.

Steps to launch an instance:

- [Initiate instance launch \(p. 562\)](#)
- [Step 1: Choose an Amazon Machine Image \(AMI\) \(p. 562\)](#)
- [Step 2: Choose an Instance Type \(p. 563\)](#)
- [Step 3: Configure Instance Details \(p. 563\)](#)
- [Step 4: Add Storage \(p. 566\)](#)
- [Step 5: Add Tags \(p. 566\)](#)
- [Step 6: Configure Security Group \(p. 566\)](#)
- [Step 7: Review Instance Launch and Select Key Pair \(p. 567\)](#)

[Initiate instance launch](#)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation bar at the top of the screen, the current Region is displayed (for example, US East (Ohio)). Select a Region for the instance that meets your needs. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. For more information, see [Resource locations \(p. 2075\)](#).
3. From the Amazon EC2 console dashboard, choose **Launch instance**.

[Step 1: Choose an Amazon Machine Image \(AMI\)](#)

When you launch an instance, you must select a configuration, known as an Amazon Machine Image (AMI). An AMI contains the information required to create a new instance. For example, an AMI might contain the software required to act as a web server, such as Windows, Apache, and your website.

When you launch an instance, you can either select an AMI from the list, or you can select a Systems Manager parameter that points to an AMI ID. For more information, see [Using a Systems Manager parameter to find an AMI](#).

On the **Choose an Amazon Machine Image (AMI)** page, use one of two options to choose an AMI. Either [search the list of AMIs \(p. 562\)](#), or [search by Systems Manager parameter \(p. 563\)](#).

By searching the list of AMIs

1. Select the type of AMI to use in the left pane:

Quick Start

A selection of popular AMIs to help you get started quickly. To select an AMI that is eligible for the free tier, choose **Free tier only** in the left pane. These AMIs are marked **Free tier eligible**.

My AMIs

The private AMIs that you own, or private AMIs that have been shared with you. To view AMIs that are shared with you, choose **Shared with me** in the left pane.

AWS Marketplace

An online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see [Launch an AWS Marketplace instance \(p. 592\)](#).

Community AMIs

The AMIs that AWS community members have made available for others to use. To filter the list of AMIs by operating system, choose the appropriate check box under **Operating system**. You can also filter by architecture and root device type.

2. Check the **Virtualization type** listed for each AMI. Notice which AMIs are the type that you need, either hvm or paravirtual. For example, some instance types require HVM.
3. Check the **Boot mode** listed for each AMI. Notice which AMIs use the boot mode that you need, either legacy-bios or uefi. For more information, see [Boot modes \(p. 28\)](#).
4. Choose an AMI that meets your needs, and then choose **Select**.

By Systems Manager parameter

1. Choose **Search by Systems Manager parameter** (at top right).
2. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears next to **Currently resolves to**.
3. Choose **Search**. The AMIs that match the AMI ID appear in the list.
4. Select the AMI from the list, and choose **Select**.

Step 2: Choose an Instance Type

On the **Choose an Instance Type** page, select the hardware configuration and size of the instance to launch. Larger instance types have more CPU and memory. For more information, see [Instance types \(p. 210\)](#).

To remain eligible for the free tier, choose the **t2.micro** instance type (or the **t3.micro** instance type in Regions where **t2.micro** is unavailable). If an instance type is eligible under the Free Tier, it is labeled **Free tier eligible**. For more information about t2.micro and t3.micro, see [Burstable performance instances \(p. 245\)](#).

By default, the wizard displays current generation instance types, and selects the first available instance type based on the AMI that you selected. To view previous generation instance types, choose **All generations** from the filter list.

Note

To set up an instance quickly for testing purposes, choose **Review and Launch** to accept the default configuration settings, and launch your instance. Otherwise, to configure your instance further, choose **Next: Configure Instance Details**.

Step 3: Configure Instance Details

On the **Configure Instance Details** page, change the following settings as necessary (expand **Advanced Details** to see all the settings), and then choose **Next: Add Storage**:

- **Number of instances:** Enter the number of instances to launch.

Tip

To ensure faster instance launches, break up large requests into smaller batches. For example, create five separate launch requests for 100 instances each instead of one launch request for 500 instances.

- (Optional) To help ensure that you maintain the correct number of instances to handle demand on your application, you can choose **Launch into Auto Scaling Group** to create a launch configuration and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).

Note

If Amazon EC2 Auto Scaling marks an instance that is in an Auto Scaling group as unhealthy, the instance is automatically scheduled for replacement where it is terminated and another is launched, and you lose your data on the original instance. An instance is marked as unhealthy if you stop or reboot the instance, or if another event marks the instance as unhealthy. For

more information, see [Health checks for Auto Scaling instances](#) in the *Amazon EC2 Auto Scaling User Guide*.

- **Purchasing option:** Choose **Request Spot instances** to launch a Spot Instance. This adds and removes options from this page. You can optionally set your maximum price (not recommended), and optionally change the request type, interruption behavior, and request validity. For more information, see [Create a Spot Instance request \(p. 407\)](#).
- **Network:** Select the VPC or to create a new VPC, choose **Create new VPC** to go the Amazon VPC console. When you have finished, return to the launch instance wizard and choose **Refresh** to load your VPC in the list.
- **Subnet:** You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone or Outpost.

To launch the instance in an Availability Zone, select the subnet into which to launch your instance. You can select **No preference** to let AWS choose a default subnet in any Availability Zone. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the wizard and choose **Refresh** to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with an Outpost.

- **Auto-assign Public IP:** Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address and instances in a nondefault subnet don't. You can select **Enable** or **Disable** to override the subnet's default setting. For more information, see [Public IPv4 addresses \(p. 1236\)](#).
- **Auto-assign IPv6 IP:** Specify whether your instance receives an IPv6 address from the range of the subnet. Select **Enable** or **Disable** to override the subnet's default setting. This option is only available if you've associated an IPv6 CIDR block with your VPC and subnet. For more information, see [Add an IPv6 CIDR block to your VPC](#) in the *Amazon VPC User Guide*.
- **Hostname type:** Select whether the guest OS hostname of the instance will include the resource name or the IP name. For more information, see [Amazon EC2 instance hostname types \(p. 1250\)](#).
- **DNS Hostname:** Determines if the DNS queries to the resource name or the IP name (depending on what you selected for **Hostname type**) will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information, see [Amazon EC2 instance hostname types \(p. 1250\)](#).
- **Domain join directory:** Select the AWS Directory Service directory (domain) to which your Windows instance is joined after launch. If you select a domain, you must select an IAM role with the required permissions. For more information, see [Seamlessly join a Windows EC2 instance](#).
- **Placement group:** A placement group determines the placement strategy of your instances. Select an existing placement group, or create a new one. This option is only available if you've selected an instance type that supports placement groups. For more information, see [Placement groups \(p. 1352\)](#).
- **Capacity Reservation:** Specify whether to launch the instance into shared capacity, any open Capacity Reservation, a specific Capacity Reservation, or a Capacity Reservation group. For more information, see [Launch instances into an existing Capacity Reservation \(p. 510\)](#).
- **IAM role:** Select an AWS Identity and Access Management (IAM) role to associate with the instance. For more information, see [IAM roles for Amazon EC2 \(p. 1649\)](#).
- **CPU options:** Choose **Specify CPU options** to specify a custom number of vCPUs during launch. Set the number of CPU cores and threads per core. For more information, see [Optimize CPU options \(p. 803\)](#).
- **Shutdown behavior:** Select whether the instance should stop or terminate when shut down. For more information, see [Change the instance initiated shutdown behavior \(p. 619\)](#).
- **Stop - Hibernate behavior:** To enable hibernation, select this check box. This option is only available if your instance meets the hibernation prerequisites. For more information, see [Hibernate your On-Demand Windows instance \(p. 602\)](#).
- **Enable termination protection:** To prevent accidental termination, select this check box. For more information, see [Enable termination protection \(p. 618\)](#).

- **Enable stop protection:** To prevent accidental stopping, select this check box. For more information, see [Enable stop protection \(p. 599\)](#).
- **Monitoring:** Select this check box to turn on detailed monitoring of your instance using Amazon CloudWatch. Additional charges apply. For more information, see [Monitor your instances using CloudWatch \(p. 1183\)](#).
- **EBS-optimized instance:** An Amazon EBS-optimized instance uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. If the instance type supports this feature, select this check box to enable it. Additional charges apply. For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).
- **Tenancy:** If you are launching your instance into a VPC, you can choose to run your instance on isolated, dedicated hardware (**Dedicated**) or on a Dedicated Host (**Dedicated host**). Additional charges may apply. For more information, see [Dedicated Instances \(p. 499\)](#) and [Dedicated Hosts \(p. 458\)](#).
- **T2/T3 Unlimited:** Select this check box to enable applications to burst beyond the baseline for as long as needed. Additional charges may apply. For more information, see [Burstable performance instances \(p. 245\)](#).
- **Network interfaces:** If you selected a specific subnet, you can specify up to two network interfaces for your instance:
 - For **Network Interface**, select **New network interface** to let AWS create a new interface, or select an existing, available network interface.
 - For **Primary IP**, enter a private IPv4 address from the range of your subnet, or leave **Auto-assign** to let AWS choose a private IPv4 address for you.
 - For **Secondary IP addresses**, choose **Add IP** to assign more than one private IPv4 address to the selected network interface.
 - (IPv6-only) For **IPv6 IPs**, choose **Add IP**, and enter an IPv6 address from the range of the subnet, or leave **Auto-assign** to let AWS choose one for you.
 - **Network Card Index:** The index of the network card. The primary network interface must be assigned to network card index **0**. Some instance types support multiple network cards.
 - Choose **Add Device** to add a secondary network interface. A secondary network interface can reside in a different subnet of the VPC, provided it's in the same Availability Zone as your instance.

For more information, see [Elastic network interfaces \(p. 1280\)](#). If you specify more than one network interface, your instance cannot receive a public IPv4 address. Additionally, if you specify an existing network interface for eth0, you cannot override the subnet's public IPv4 setting using **Auto-assign Public IP**. For more information, see [Assign a public IPv4 address during instance launch \(p. 1239\)](#).

- **Kernel ID:** (Only valid for paravirtual (PV) AMIs) Select **Use default** unless you want to use a specific kernel.
- **RAM disk ID:** (Only valid for paravirtual (PV) AMIs) Select **Use default** unless you want to use a specific RAM disk. If you have selected a kernel, you may need to select a specific RAM disk with the drivers to support it.
- **Enclave:** Select **Enable** to enable the instance for AWS Nitro Enclaves. For more information, see [What is AWS Nitro Enclaves?](#) in the *AWS Nitro Enclaves User Guide*.
- **Metadata accessible:** You can enable or disable access to the Instance Metadata Service (IMDS). For more information, see [Use IMDSv2 \(p. 863\)](#).
- **Metadata transport:** Enable the instance to reach the link local IMDSv2 IPv6 address (fd00:ec2::254) to retrieve instance metadata. This option is only available if you are launching [Instances built on the Nitro System \(p. 218\)](#) into an [IPv6-only subnet](#). For more information about retrieving instance metadata, see [Retrieve instance metadata \(p. 876\)](#).
- **Metadata version:** If you enable access to the IMDS, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances \(p. 869\)](#).
- **Metadata token response hop limit:** If you enable the IMDS, you can set the allowable number of network hops for the metadata token. For more information, see [Use IMDSv2 \(p. 863\)](#).

- **User data:** You can specify user data to configure an instance during launch, or to run a configuration script. To attach a file, select the **As file** option and browse for the file to attach.

Step 4: Add Storage

The AMI you selected includes one or more volumes of storage, including the root device volume. On the **Add Storage** page, you can specify additional volumes to attach to the instance by choosing **Add New Volume**. Configure each volume as follows, and then choose **Next: Add Tags**.

- **Type:** Select instance store or Amazon EBS volumes to associate with your instance. The types of volume available in the list depend on the instance type you've chosen. For more information, see [Amazon EC2 instance store \(p. 1996\)](#) and [Amazon EBS volumes \(p. 1704\)](#).
- **Device:** Select from the list of available device names for the volume.
- **Snapshot:** Enter the name or ID of the snapshot from which to restore a volume. You can also search for available shared and public snapshots by typing text into the **Snapshot** field. Snapshot descriptions are case-sensitive.
- **Size:** For EBS volumes, you can specify a storage size. Even if you have selected an AMI and instance that are eligible for the free tier, to stay within the free tier, you must stay under 30 GiB of total storage. For more information, see [Constraints on the size and configuration of an EBS volume \(p. 1724\)](#).
- **Volume Type:** For EBS volumes, select a volume type. For more information, see [Amazon EBS volume types \(p. 1707\)](#).
- **IOPS:** If you have selected a Provisioned IOPS SSD volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support.
- **Delete on Termination:** For Amazon EBS volumes, select this check box to delete the volume when the instance is terminated. For more information, see [Preserve Amazon EBS volumes on instance termination \(p. 620\)](#).
- **Encrypted:** If the instance type supports EBS encryption, you can specify the encryption state of the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or disable encryption. For more information, see [Amazon EBS encryption \(p. 1921\)](#).

Step 5: Add Tags

On the **Add Tags** page, specify [tags \(p. 2085\)](#) by providing key and value combinations. You can tag the instance, the volumes, or both. For Spot Instances, you can tag the Spot Instance request only. Choose **Add another tag** to add more than one tag to your resources. Choose **Next: Configure Security Group** when you are done.

Step 6: Configure Security Group

On the **Configure Security Group** page, use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. (For more information about security groups, see [Amazon EC2 security groups for Windows instances \(p. 1674\)](#).) Select or create a security group as follows, and then choose **Review and Launch**.

- To select an existing security group, choose **Select an existing security group**, and select your security group. You can't edit the rules of an existing security group, but you can copy them to a new group by choosing **Copy to new**. Then you can add rules as described in the next step.
- To create a new security group, choose **Create a new security group**. The wizard automatically defines the **launch-wizard-x** security group and creates an inbound rule to allow you to connect to your instance over RDP (port 3389).
- You can add rules to suit your needs. For example, if your instance is a web server, open ports 80 (HTTP) and 443 (HTTPS) to allow internet traffic.

To add a rule, choose **Add Rule**, select the protocol to open to network traffic, and then specify the source. Choose **My IP** from the **Source** list to let the wizard add your computer's public IP address. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

Warning

Rules that enable all IP addresses ($0.0.0.0/0$) to access your instance over SSH or RDP are acceptable for this short exercise, but are unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

Step 7: Review Instance Launch and Select Key Pair

On the **Review Instance Launch** page, check the details of your instance, and make any necessary changes by choosing the appropriate **Edit** link.

When you are ready, choose **Launch**.

In the **Select an existing key pair or create a new key pair** dialog box, you can choose an existing key pair, or create a new one. For example, choose **Choose an existing key pair**, then select the key pair you created when getting set up. For more information, see [Amazon EC2 key pairs and Windows instances \(p. 1662\)](#).

Important

If you choose the **Proceed without key pair** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

To launch your instance, select the acknowledgment check box, then choose **Launch Instances**.

(Optional) You can create a status check alarm for the instance (additional fees may apply). On the confirmation screen, choose **Create status check alarms** and follow the directions. Status check alarms can also be created after you launch the instance. For more information, see [Create and edit status check alarms \(p. 1157\)](#).

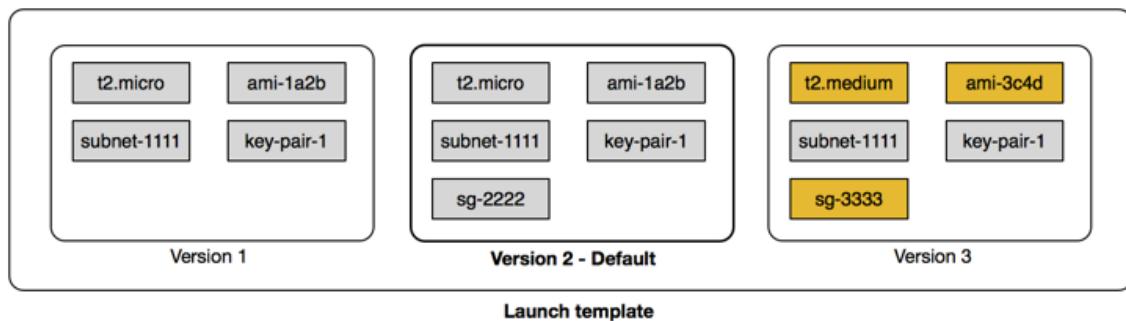

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 2114\)](#).

Launch an instance from a launch template

You can create a *launch template* that contains the configuration information to launch an instance. You can use launch templates to store launch parameters so that you do not have to specify them every time you launch an instance. For example, a launch template can contain the AMI ID, instance type, and network settings that you typically use to launch instances. When you launch an instance using the Amazon EC2 console, an AWS SDK, or a command line tool, you can specify the launch template to use.

For each launch template, you can create one or more numbered *launch template versions*. Each version can have different launch parameters. When you launch an instance from a launch template, you can use any version of the launch template. If you do not specify a version, the default version is used. You can set any version of the launch template as the default version—by default, it's the first version of the launch template.

The following diagram shows a launch template with three versions. The first version specifies the instance type, AMI ID, subnet, and key pair to use to launch the instance. The second version is based on the first version and also specifies a security group for the instance. The third version uses different values for some of the parameters. Version 2 is set as the default version. If you launched an instance from this launch template, the launch parameters from version 2 would be used if no other version were specified.

Contents

- [Launch template restrictions \(p. 568\)](#)
- [Use launch templates to control launching instances \(p. 568\)](#)
- [Create a launch template \(p. 570\)](#)
- [Modify a launch template \(manage launch template versions\) \(p. 583\)](#)
- [Delete a launch template \(p. 586\)](#)
- [Launch instances from a launch template \(p. 586\)](#)

Launch template restrictions

The following rules apply to launch templates and launch template versions:

- **Quotas** – To view the quotas for your launch templates and launch template versions, open the [Service Quotas](#) console or use the [list-service-quotas](#) AWS CLI command. Each AWS account can have up to a maximum of 5,000 launch templates per Region and up to 10,000 versions per launch template. Your accounts might have different quotas based on their age and usage history.
- **Parameters are optional** – Launch template parameters are optional. However, you must ensure that your request to launch an instance includes all the required parameters. For example, if your launch template does not include an AMI ID, you must specify both the launch template and an AMI ID when you launch an instance.
- **Parameters not validated** – Launch template parameters are not fully validated when you create the launch template. If you specify incorrect values for parameters, or if you do not use supported parameter combinations, no instances can launch using this launch template. Ensure that you specify the correct values for the parameters and that you use supported parameter combinations. For example, to launch an instance in a placement group, you must specify a supported instance type.
- **Tags** – You can tag a launch template, but you cannot tag a launch template version.
- **Immutable** – Launch templates are immutable. To modify a launch template, you must create a new version of the launch template.
- **Version numbers** – Launch template versions are numbered in the order in which they are created. When you create a launch template version, you cannot specify the version number yourself.

Use launch templates to control launching instances

You can specify that users can only launch instances if they use a launch template, and that they can only use a specific launch template. You can also control who can create, modify, describe, and delete launch templates and launch template versions.

Use launch templates to control launch parameters

A launch template can contain all or some of the parameters to launch an instance. When you launch an instance using a launch template, you can override parameters that are specified in the launch template. Or, you can specify additional parameters that are not in the launch template.

Note

You cannot remove launch template parameters during launch (for example, you cannot specify a null value for the parameter). To remove a parameter, create a new version of the launch template without the parameter and use that version to launch the instance.

To launch instances, users must have permissions to use the `ec2:RunInstances` action. Users must also have permissions to create or use the resources that are created or associated with the instance. You can use resource-level permissions for the `ec2:RunInstances` action to control the launch parameters that users can specify. Alternatively, you can grant users permissions to launch an instance using a launch template. This enables you to manage launch parameters in a launch template rather than in an IAM policy, and to use a launch template as an authorization vehicle for launching instances. For example, you can specify that users can only launch instances using a launch template, and that they can only use a specific launch template. You can also control the launch parameters that users can override in the launch template. For example policies, see [Launch templates \(p. 1624\)](#).

Control the use of launch templates

By default, users do not have permissions to work with launch templates. You can create a policy that grants users permissions to create, modify, describe, and delete launch templates and launch template versions. You can also apply resource-level permissions to some launch template actions to control a user's ability to use specific resources for those actions. For more information, see the following example policies: [Example: Work with launch templates \(p. 1635\)](#).

Take care when granting users permissions to use the `ec2:CreateLaunchTemplate` and `ec2:CreateLaunchTemplateVersion` actions. You cannot use resource-level permissions to control which resources users can specify in the launch template. To restrict the resources that are used to launch an instance, ensure that you grant permissions to create launch templates and launch template versions only to appropriate administrators.

Important security concerns when using launch templates with EC2 Fleet or Spot Fleet

To use launch templates, you must grant your users permissions to create, modify, describe, and delete launch templates and launch template versions. You can control who can create launch templates and launch template versions by controlling access to the `ec2:CreateLaunchTemplate` and `ec2:CreateLaunchTemplateVersion` actions. You can also control who can modify launch templates by controlling access to the `ec2:ModifyLaunchTemplate` action.

Important

If an EC2 Fleet or Spot Fleet is configured to use the Latest or Default launch template version, the fleet is not aware if Latest or Default are later changed to point to a different launch template version. When a different launch template version is used for Latest or Default, Amazon EC2 does not re-check permissions for actions to be completed when launching new instances to fulfil the fleet's target capacity. This is an important consideration when granting permissions to who can create and manage launch template versions, particularly the `ec2:ModifyLaunchTemplate` action that allows a user to change the Default launch template version.

By granting a user permission to use the EC2 actions for the launch template APIs, the user is effectively also granted the `iam:PassRole` permission if they create or update an EC2 Fleet or Spot Fleet to point to a different launch template version that contains an instance profile (a container for an IAM role). It means that a user can potentially update a launch template to pass an IAM role to an instance even if they don't have the `iam:PassRole` permission. For more information and an example IAM policy, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the *IAM User Guide*.

For more information, see [Control the use of launch templates \(p. 569\)](#) and [Example: Work with launch templates \(p. 1635\)](#).

Create a launch template

Create a new launch template using parameters that you define, or use an existing launch template or an instance as the basis for a new launch template.

Tasks

- [Create a new launch template using parameters you define \(p. 570\)](#)
- [Create a launch template from an existing launch template \(p. 578\)](#)
- [Create a launch template from an instance \(p. 579\)](#)
- [Use a Systems Manager parameter instead of an AMI ID \(p. 580\)](#)

Create a new launch template using parameters you define

You can create a launch template using the console or the AWS CLI:

- [Console \(p. 570\)](#)
- [AWS CLI \(p. 577\)](#)

Console

To create a launch template, you must specify the launch template name and at least one instance configuration parameter.

The launch template parameters are grouped in the launch template. The following instructions take you through each parameter group.

Parameters for launch template configuration

- [Start launch template creation \(p. 570\)](#)
- [Launch template name, description, and tags \(p. 570\)](#)
- [Application and OS Images \(Amazon Machine Image\) \(p. 571\)](#)
- [Instance type \(p. 572\)](#)
- [Key pair \(login\) \(p. 572\)](#)
- [Network settings \(p. 572\)](#)
- [Configure storage \(p. 574\)](#)
- [Resource tags \(p. 575\)](#)
- [Advanced details \(p. 575\)](#)
- [Summary \(p. 577\)](#)

Start launch template creation

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.

Launch template name, description, and tags

1. For **Launch template name**, enter a descriptive name for the launch template.
2. For **Template version description**, provide a brief description of this version of the launch template.

3. To [tag \(p. 2085\)](#) the launch template on creation, expand **Template tags**, choose **Add tag**, and then enter a tag key and value pair. Choose **Add tag** again for each additional tag to add.

Note

To tag the resources that are created when an instance is launched, you must specify the tags under **Resource tags**. For more information, see [Resource tags \(p. 575\)](#).

Application and OS Images (Amazon Machine Image)

An Amazon Machine Image (AMI) contains the information required to create an instance. For example, an AMI might contain the software that's required to act as a web server, such as Windows, Apache, and your website.

You can find a suitable AMI as follows. With each option for finding an AMI, you can choose **Cancel** (at top right) to return to the launch template without choosing an AMI.

Search bar

To search through all available AMIs, enter a keyword in the AMI search bar and then press **Enter**. To select an AMI, choose **Select**.

Recents

The AMIs that you've recently used.

Choose **Recently launched** or **Currently in use**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

My AMIs

The private AMIs that you own, or private AMIs that have been shared with you.

Choose **Owned by me** or **Shared with me**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

Quick Start

AMIs are grouped by operating system (OS) to help you get started quickly.

First select the OS that you need, and then, from **Amazon Machine Image (AMI)**, select an AMI. To select an AMI that is eligible for the free tier, make sure that the AMI is marked **Free tier eligible**.

Browse more AMIs

Choose **Browse more AMIs** to browse the full AMI catalog.

- To search through all available AMIs, enter a keyword in the search bar and then press **Enter**.
- To find an AMI using a Systems Manager parameter, choose the arrow button to the right of the search bar, and then choose **Search by Systems Manager parameter**. For more information, see [Use a Systems Manager parameter to find an AMI \(p. 126\)](#).
- To specify a Systems Manager parameter that will resolve to an AMI at the time an instance is launched from the launch template, choose the arrow button to the right of the search bar, and then choose **Specify custom value/Systems Manager parameter**. For more information, see [Use a Systems Manager parameter instead of an AMI ID \(p. 580\)](#).
- To search by category, choose **Quickstart AMIs**, **My AMIs**, **AWS Marketplace AMIs**, or **Community AMIs**.

The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see [Launch an AWS Marketplace instance \(p. 592\)](#). In **Community AMIs**, you can find AMIs that AWS community members have made available for others to use. AMIs from Amazon or a verified partner are marked **Verified provider**.

- To filter the list of AMIs, select one or more check boxes under **Refine results** on the left of the screen. The filter options are different depending on the selected search category.
- Check the **Virtualization** type listed for each AMI. Notice which AMIs are the type that you need: either **hvm** or **paravirtual**. For example, some instance types require HVM.
- Check the **Boot mode** listed for each AMI. Notice which AMIs use the boot mode that you need: either **legacy-bios**, **uefi**, or **uefi-preferred**. For more information, see [Boot modes \(p. 28\)](#).
- Choose an AMI that meets your needs, and then choose **Select**.

Instance type

The instance type defines the hardware configuration and size of the instance. Larger instance types have more CPU and memory. For more information, see [Instance types](#).

For **Instance type**, you can either select an instance type, or you can specify instance attributes and let Amazon EC2 identify the instance types with those attributes.

Note

Specifying instance attributes is supported only when using Auto Scaling groups, EC2 Fleet, and Spot Fleet to launch instances. For more information, see [Creating an Auto Scaling group using attribute-based instance type selection](#), [Attribute-based instance type selection for EC2 Fleet \(p. 986\)](#), and [Attribute-based instance type selection for Spot Fleet \(p. 1030\)](#).

If you plan to use the launch template in the [launch instance wizard \(p. 552\)](#) or with the [RunInstances API](#), you must select an instance type.

- **Instance type:** Ensure that the instance type is compatible with the AMI that you've specified. For more information, see [Instance types \(p. 210\)](#).
- **Compare instance types:** You can compare different instance types by the following attributes: number of vCPUs, architecture, amount of memory (GiB), amount of storage (GB), storage type, and network performance.
- **Advanced:** To specify instance attributes and let Amazon EC2 identify the instance types with those attributes, choose **Advanced**, and then choose **Specify instance type attributes**.
 - **Number of vCPUs:** Enter the minimum and maximum number of vCPUs for your compute requirements. To indicate no limits, enter a minimum of **0**, and leave the maximum blank.
 - **Amount of memory (MiB):** Enter the minimum and maximum amount of memory, in MiB, for your compute requirements. To indicate no limits, enter a minimum of **0**, and leave the maximum blank.
 - Expand **Optional instance type attributes** and choose **Add attribute** to express your compute requirements in more detail. For information about each attribute, see [InstanceRequirementsRequest](#) in the *Amazon EC2 API Reference*.
 - **Resulting instance types:** You can preview the instance types that match the specified attributes. To exclude instance types, choose **Add attribute**, and from the **Attribute** list, choose **Excluded instance types**. From the **Attribute value** list, select the instance types to exclude.

Key pair (login)

The key pair for the instance.

For **Key pair name**, choose an existing key pair, or choose **Create new key pair** to create a new one. For more information, see [Amazon EC2 key pairs and Windows instances \(p. 1662\)](#).

Network settings

Configure the network settings, as necessary.

- **Subnet:** You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone, or Outpost.

To launch the instance in an Availability Zone, select the subnet in which to launch your instance. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the wizard and choose the Refresh icon to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with the Outpost.

- **Firewall (security groups):** Use one or more security groups to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. For more information about security groups, see [Amazon EC2 security groups for Windows instances \(p. 1674\)](#).

If you add a network interface, you must specify the same security groups in the network interface.

Select or create a security group as follows:

- To select an existing security group, choose **Select existing security group**, and select your security group from **Common security groups**.
- To create a new security group, choose **Create security group**.

You can add rules to suit your needs. For example, if your instance will be a web server, open ports 80 (HTTP) and 443 (HTTPS) to allow internet traffic.

To add a rule, choose **Add security group rule**. For **Type**, select the network traffic type. The **Protocol** field is automatically filled in with the protocol to open to network traffic. For **Source type**, select the source type. To let the launch template add your computer's public IP address, choose **My IP**. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

Warning

Rules that enable all IP addresses (`0.0.0.0/0`) to access your instance over SSH or RDP are acceptable if you are briefly launching a test instance and will stop or terminate it soon, but are unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

- **Advanced network configuration**

Network interface

- **Device index:** The device number for the network interface, for example, `eth0` for the primary network interface. If you leave the field blank, AWS creates the primary network interface.
- **Network interface:** Select **New interface** to let Amazon EC2 create a new interface, or select an existing, available network interface.
- **Description:** (Optional) A description for the new network interface.
- **Subnet:** The subnet in which to create the new network interface. For the primary network interface (`eth0`), this is the subnet in which the instance is launched. If you've entered an existing network interface for `eth0`, the instance is launched in the subnet in which the network interface is located.
- **Security groups:** One or more security groups in your VPC with which to associate the network interface.
- **Auto-assign public IP:** Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address and instances in a nondefault subnet do not. You can select **Enable** or **Disable** to override the subnet's default setting. For more information, see [Public IPv4 addresses \(p. 1236\)](#).
- **Primary IP:** A private IPv4 address from the range of your subnet. Leave blank to let Amazon EC2 choose a private IPv4 address for you.
- **Secondary IP:** One or more additional private IPv4 addresses from the range of your subnet. Choose **Manually assign** and enter an IP address. Choose **Add IP** to add another IP address. Alternatively,

choose **Automatically assign** to let Amazon EC2 choose one for you, and enter a value to indicate the number of IP addresses to add.

- (**IPv6-only**) **IPv6 IPs**: An IPv6 address from the range of the subnet. Choose **Manually assign** and enter an IP address. Choose **Add IP** to add another IP address. Alternatively, choose **Automatically assign** to let Amazon EC2 choose one for you, and enter a value to indicate the number of IP addresses to add.
- **IPv4 Prefixes**: The IPv4 prefixes for the network interface.
- **IPv6 Prefixes**: The IPv6 prefixes for the network interface.
- (**Optional**) **Assign Primary IPv6 IP**: If you're launching an instance into a dual-stack or IPv6-only subnet, you have the option to **Assign Primary IPv6 IP**. Assigning a primary IPv6 address enables you to avoid disrupting traffic to instances or ENIs. Choose **Enable** if this instance relies on its IPv6 address not changing. When you launch the instance, AWS will automatically assign an IPv6 address associated with the ENI attached to your instance to be the primary IPv6 address. Once you enable an IPv6 GUA address to be a primary IPv6, you cannot disable it. When you enable an IPv6 GUA address to be a primary IPv6, the first IPv6 GUA will be made the primary IPv6 address until the instance is terminated or the network interface is detached. If you have multiple IPv6 addresses associated with an ENI attached to your instance and you enable a primary IPv6 address, the first IPv6 GUA address associated with the ENI becomes the primary IPv6 address.
- **Delete on termination**: Whether the network interface is deleted when the instance is deleted.
- **Elastic Fabric Adapter**: Indicates whether the network interface is an Elastic Fabric Adapter. For more information, see [Elastic Fabric Adapter](#).
- **Network card index**: The index of the network card. The primary network interface must be assigned to network card index **0**. Some instance types support multiple network cards.

Choose **Add network interface** to add more network interfaces. The number of network interfaces that you can add depends on the number that is supported by the selected instance type. A secondary network interface can reside in a different subnet of the VPC, provided it's in the same Availability Zone as your instance.

For more information, see [Elastic network interfaces \(p. 1280\)](#). If you specify more than one network interface, your instance cannot receive a public IPv4 address. Additionally, if you specify an existing network interface for eth0, you cannot override the subnet's public IPv4 setting using **Auto-assign Public IP**. For more information, see [Assign a public IPv4 address during instance launch \(p. 1239\)](#).

Configure storage

If you specify an AMI for the launch template, the AMI includes one or more volumes of storage, including the root volume (**Volume 1 (AMI Root)**). You can specify additional volumes to attach to the instance.

You can use the **Simple** or **Advanced** view. With the **Simple** view, you specify the size and type of volume. To specify all volume parameters, choose the **Advanced** view (at top right of the card).

To add a new volume, choose **Add new volume**.

By using the **Advanced** view, you can configure each volume as follows:

- **Storage type**: The type of volume (EBS or ephemeral) to associate with your instance. The instance store (ephemeral) volume type is only available if you select an instance type that supports it. For more information, see [Amazon EC2 instance store \(p. 1996\)](#) and [Amazon EBS volumes \(p. 1704\)](#).
- **Device name**: Select from the list of available device names for the volume.
- **Snapshot**: Select the snapshot from which to create the volume. You can search for available shared and public snapshots by entering text into the **Snapshot** field.
- **Size (GiB)**: For EBS volumes, you can specify a storage size. If you have selected an AMI and instance that are eligible for the free tier, keep in mind that to stay within the free tier, you must stay under 30

GiB of total storage. For more information, see [Constraints on the size and configuration of an EBS volume \(p. 1724\)](#).

- **Volume type:** For EBS volumes, select a volume type. For more information, see [Amazon EBS volume types \(p. 1707\)](#).
- **IOPS:** If you have selected a Provisioned IOPS SSD (io1 and io2) or General Purpose SSD (gp3) volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support. This is required for io1, io2, and gp3 volumes. It is not supported for gp2, st1, sc1, or standard volumes. If you omit this parameter for the launch template, you must specify a value for it when you launch an instance from the launch template.
- **Delete on termination:** For Amazon EBS volumes, choose **Yes** to delete the volume when the instance is terminated, or choose **No** to keep the volume. For more information, see [Preserve Amazon EBS volumes on instance termination \(p. 620\)](#).
- **Encrypted:** If the instance type supports EBS encryption, you can choose **Yes** to enable encryption for the volume. If you have enabled encryption by default in this Region, encryption is enabled for you. For more information, see [Amazon EBS encryption \(p. 1921\)](#).
- **KMS key:** If you selected **Yes** for **Encrypted**, then you must select a customer managed key to use to encrypt the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or specify the ARN of any customer managed key that you created.

Resource tags

To [tag \(p. 2085\)](#) the resources that are created when an instance is launched, under **Resource tags**, choose **Add tag**, and then enter a tag key and value pair. For **Resource types**, specify the resources to tag on creation. You can specify the same tag for all the resources, or specify different tags for different resources. Choose **Add tag** again for each additional tag to add.

You can specify tags for the following resources that are created when a launch template is used:

- Instances
- Volumes
- Elastic graphics
- Spot Instance requests
- Network interfaces

Note

To tag the launch template itself, you must specify the tags under **Template tags**. For more information, see [Launch template name, description, and tags \(p. 570\)](#).

Advanced details

For **Advanced details**, expand the section to view the fields and specify any additional parameters for the instance.

- **Purchasing option:** Choose **Request Spot Instances** to request Spot Instances at the Spot price, capped at the On-Demand price, and choose **Customize** to change the default Spot Instance settings. You can set your maximum price (not recommended), and change the request type, request duration, and interruption behavior. If you do not request a Spot Instance, EC2 launches an On-Demand Instance by default. For more information, see [Spot Instances \(p. 394\)](#).
- **IAM instance profile:** Select an AWS Identity and Access Management (IAM) instance profile to associate with the instance. For more information, see [IAM roles for Amazon EC2 \(p. 1649\)](#).
- **Hostname type:** Select whether the guest OS hostname of the instance will include the resource name or the IP name. For more information, see [Amazon EC2 instance hostname types \(p. 1250\)](#).

- **DNS Hostname:** Determines if the DNS queries to the resource name or the IP name (depending on what you selected for **Hostname type**) will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information, see [Amazon EC2 instance hostname types \(p. 1250\)](#).
- **Shutdown behavior:** Select whether the instance should stop or terminate when shut down. For more information, see [Change the instance initiated shutdown behavior \(p. 619\)](#).
- **Stop - Hibernate behavior:** To enable hibernation, choose **Enable**. This field is only valid for instances that meet the hibernation prerequisites. For more information, see [Hibernate your On-Demand Windows instance \(p. 602\)](#).
- **Termination protection:** To prevent accidental termination, choose **Enable**. For more information, see [Enable termination protection \(p. 618\)](#).
- **Stop protection:** To prevent accidental stopping, choose **Enable**. For more information, see [Enable stop protection \(p. 599\)](#).
- **Detailed CloudWatch monitoring:** Choose **Enable** to enable detailed monitoring of the instance using Amazon CloudWatch. Additional charges apply. For more information, see [Monitor your instances using CloudWatch \(p. 1183\)](#).
- **Elastic GPU:** Select an Elastic Graphics accelerator to attach to the instance. Not all instance types support Elastic Graphics. For more information, see [Amazon Elastic Graphics \(p. 1135\)](#).
- **Elastic inference:** An elastic inference accelerator to attach to your EC2 CPU instance. For more information, see [Working with Amazon Elastic Inference](#) in the *Amazon Elastic Inference Developer Guide*.

Note

Starting April 15, 2023, AWS will not onboard new customers to Amazon Elastic Inference (EI), and will help current customers migrate their workloads to options that offer better price and performance. After April 15, 2023, new customers will not be able to launch instances with Amazon EI accelerators in Amazon SageMaker, Amazon ECS, or Amazon EC2. However, customers who have used Amazon EI at least once during the past 30-day period are considered current customers and will be able to continue using the service.

- **Credit specification:** Choose **Unlimited** to enable applications to burst beyond the baseline for as long as needed. This field is only valid for T instances. Additional charges may apply. For more information, see [Burstable performance instances \(p. 245\)](#).
- **Placement group name:** Specify a placement group in which to launch the instance. You can select an existing placement group, or create a new one. Not all instance types can be launched in a placement group. For more information, see [Placement groups \(p. 1352\)](#).
- **EBS-optimized instance:** Select **Enable** to provide additional, dedicated capacity for Amazon EBS I/O. Not all instance types support this feature. Additional charges apply. For more information, see [Amazon EBS-optimized instances \(p. 1941\)](#).
- **Capacity Reservation:** Specify whether to launch the instance into any open Capacity Reservation (**Open**), a specific Capacity Reservation (**Target by ID**), or a Capacity Reservation group (**Target by group**). To specify that a Capacity Reservation should not be used, choose **None**. For more information, see [Launch instances into an existing Capacity Reservation \(p. 510\)](#).
- **Tenancy:** Choose whether to run your instance on shared hardware (**Shared**), isolated, dedicated hardware (**Dedicated**), or on a Dedicated Host (**Dedicated host**). If you choose to launch the instance onto a Dedicated Host, you can specify whether to launch the instance into a host resource group or you can target a specific Dedicated Host. Additional charges may apply. For more information, see [Dedicated Instances \(p. 499\)](#) and [Dedicated Hosts \(p. 458\)](#).
- **RAM disk ID:** (Only valid for paravirtual (PV) AMIs) Select a RAM disk for the instance. If you have selected a kernel, you might need to select a specific RAM disk with the drivers to support it.
- **Kernel ID:** (Only valid for paravirtual (PV) AMIs) Select a kernel for the instance.
- **Nitro Enclave:** Allows you to create isolated execution environments, called enclaves, from Amazon EC2 instances. Select **Enable** to enable the instance for AWS Nitro Enclaves. For more information, see [What is AWS Nitro Enclaves?](#) in the *AWS Nitro Enclaves User Guide*.

- **License configurations:** You can launch instances against the specified license configuration to track your license usage. For more information, see [Create a license configuration](#) in the *AWS License Manager User Guide*.
- **Specify CPU options:** Choose **Specify CPU options** to specify a custom number of vCPUs during launch. Set the number of CPU cores and threads per core. For more information, see [Optimize CPU options \(p. 803\)](#).
- **Metadata transport:** You can enable or disable the access method to the Instance Metadata Service (IMDS) that's available for this EC2 instance based on the IP address type (IPv4, IPv6, or IPv4 and IPv6) of the instance. For more information, see [Retrieve instance metadata \(p. 876\)](#).
- **Metadata accessible:** You can enable or disable access to the IMDS. For more information, see [Configure instance metadata options for new instances \(p. 869\)](#).
- **Metadata version:** If you enable access to the IMDS, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances \(p. 869\)](#).
- **Metadata response hop limit:** If you enable the IMDS, you can set the allowable number of network hops for the metadata token. For more information, see [Configure instance metadata options for new instances \(p. 869\)](#).
- **Allow tags in metadata:** If you select **Enable**, the instance will allow access to all of its instance's tags from its metadata. If you do not include this setting in the template, by default, access to the tags in instance metadata is not allowed. For more information, see [Allow access to tags in instance metadata \(p. 2097\)](#).
- **User data:** You can specify user data to configure an instance during launch, or to run a configuration script. For more information, see [Run commands on your Windows instance at launch \(p. 853\)](#).

Summary

Use the **Summary** panel to review your launch template configuration and to create your launch template.

- Review the details of your launch template, and make any necessary changes. You can navigate directly to a section by choosing its link in the **Summary** panel.
- When you're ready to create your launch template, choose **Create launch template**.

AWS CLI

To create a launch template, you must specify the launch template name and at least one instance configuration parameter.

To create a launch template using the AWS CLI

- Use the [create-launch-template](#) command. The following example creates a launch template that specifies the following:
 - A name for the launch template (*TemplateForWebServer*)
 - A description for the launch template (*WebVersion1*)
 - A tag for the launch template (*purpose=production*)
 - The data for the instance configuration, specified in a JSON file:
 - The instance type (*r4.4xlarge*) and AMI (*ami-8c1be5f6*) to launch
 - The number of cores (*4*) and threads per core (*2*) for a total of 8 vCPUs (4 cores x 2 threads)
 - The subnet in which to launch the instance (*subnet-7b16de0c*)
 - A public IP address and an IPv6 address to be assigned to the instance
 - A tag for the instance (*Name=webserver*)

```
aws ec2 create-launch-template \
--launch-template-name TemplateForWebServer \
--version-description WebVersion1 \
--tag-specifications 'ResourceType=launch-
template,Tags=[{Key=purpose,Value=production}]' \
--launch-template-data file:///template-data.json
```

The following is an example JSON file that contains the launch template data for the instance configuration.

```
{
    "NetworkInterfaces": [
        {
            "AssociatePublicIpAddress": true,
            "DeviceIndex": 0,
            "Ipv6AddressCount": 1,
            "SubnetId": "subnet-7b16de0c"
        }
    ],
    "ImageId": "ami-8c1be5f6",
    "InstanceType": "r4.4xlarge",
    "TagSpecifications": [
        {
            "ResourceType": "instance",
            "Tags": [
                {
                    "Key": "Name",
                    "Value": "webserver"
                }
            ]
        }
    ],
    "CpuOptions": {
        "CoreCount": 4,
        "ThreadsPerCore": 2
    }
}
```

The following is example output.

```
{
    "LaunchTemplate": {
        "LatestVersionNumber": 1,
        "LaunchTemplateId": "lt-01238c059e3466abc",
        "LaunchTemplateName": "TemplateForWebServer",
        "DefaultVersionNumber": 1,
        "CreatedBy": "arn:aws:iam::123456789012:root",
        "CreateTime": "2017-11-27T09:13:24.000Z"
    }
}
```

Create a launch template from an existing launch template

You can clone an existing launch template and then adjust the parameters to create a new launch template. However, you can only do this when using the Amazon EC2 console; the AWS CLI does not support cloning a template.

Console

To create a launch template from an existing launch template

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.

3. For **Launch template name**, enter a descriptive name for the launch template.
4. For **Template version description**, provide a brief description of this version of the launch template.
5. To tag the launch template on creation, expand **Template tags**, choose **Add tag**, and then enter a tag key and value pair.
6. Expand **Source template**, and for **Launch template name** choose a launch template on which to base the new launch template.
7. For **Source template version**, choose the launch template version on which to base the new launch template.
8. Adjust any launch parameters as required, and then choose **Create launch template**.

Create a launch template from an instance

Console

To create a launch template from an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and choose **Actions**, **Create template from instance**.
4. Provide a name, description, and tags, and adjust the launch parameters as required.

Note

When you create a launch template from an instance, the instance's network interface IDs and IP addresses are not included in the template.

5. Choose **Create launch template**.

AWS CLI

You can use the AWS CLI to create a launch template from an existing instance by first getting the launch template data from an instance, and then creating a launch template using the launch template data.

To get launch template data from an instance

- Use the [get-launch-template-data](#) command and specify the instance ID. You can use the output as a base to create a new launch template or launch template version. By default, the output includes a top-level LaunchTemplateData object, which cannot be specified in your launch template data. Use the `--query` option to exclude this object.

```
aws ec2 get-launch-template-data \
--instance-id i-0123d646e8048babc \
--query "LaunchTemplateData"
```

The following is example output.

```
{
    "Monitoring": [],
    "ImageId": "ami-8c1be5f6",
    "BlockDeviceMappings": [
        {
            "DeviceName": "/dev/xvda",
            "Ebs": {
                "DeleteOnTermination": true
            }
        }
    ]
}
```

```
        }
    ],
    "EbsOptimized": false,
    "Placement": {
        "Tenancy": "default",
        "GroupName": "",
        "AvailabilityZone": "us-east-1a"
    },
    "InstanceType": "t2.micro",
    "NetworkInterfaces": [
        {
            "Description": "",
            "NetworkInterfaceId": "eni-35306abc",
            "PrivateIpAddresses": [
                {
                    "Primary": true,
                    "PrivateIpAddress": "10.0.0.72"
                }
            ],
            "SubnetId": "subnet-7b16de0c",
            "Groups": [
                "sg-7c227019"
            ],
            "Ipv6Addresses": [
                {
                    "Ipv6Address": "2001:db8:1234:1a00::123"
                }
            ],
            "PrivateIpAddress": "10.0.0.72"
        }
    ]
}
```

You can write the output directly to a file, for example:

```
aws ec2 get-launch-template-data \
--instance-id i-0123d646e8048babc \
--query "LaunchTemplateData" >> instance-data.json
```

To create a launch template using launch template data

- Use the [create-launch-template](#) command to create a launch template using the output from the previous procedure. For more information about creating a launch template using the AWS CLI, see [Create a new launch template using parameters you define \(p. 570\)](#).

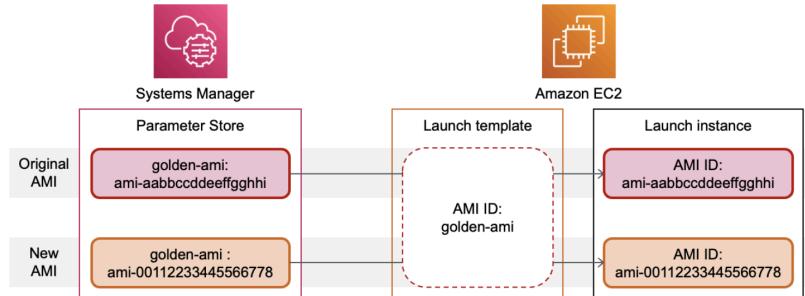

Use a Systems Manager parameter instead of an AMI ID

Instead of specifying an AMI ID in your launch templates, you can specify an AWS Systems Manager parameter. If the AMI ID changes, you can update the AMI ID in one place by updating the Systems Manager parameter in the Systems Manager Parameter Store. By using a Systems Manager parameter, all your launch templates can be updated in a single action.

A Systems Manager parameter is a user-defined key-value pair that you create in the Systems Manager Parameter Store. The Parameter Store provides a central place to store your application configuration values. For more information, see [AWS Systems Manager Parameter Store](#) in the *AWS Systems Manager User Guide*.

In the following diagram, the `golden-ami` parameter is first mapped to the original AMI `aabbccddeeffgghhi` in the Parameter Store. In the launch template, the value for the AMI ID is

golden-ami. When an instance is launched using this launch template, the AMI ID resolves to ami-aabbccddeeffgghhi. Later, the AMI is updated resulting in a new AMI ID. In the Parameter Store, the golden-ami parameter is mapped to the new ami-00112233445566778. *The launch template remains unchanged.* When an instance is launched using this launch template, the AMI ID resolves to the new ami-00112233445566778.

Systems Manager parameter format for AMI IDs

Launch templates require that user-defined Systems Manager parameters adhere to the following format when used in place of an AMI ID:

- Parameter type: `String`
- Parameter data type: `aws:ec2:image` – This ensures that Parameter Store validates that the value you enter is in the proper format for an AMI ID.

For more information about creating a valid parameter for an AMI ID, see [Creating Systems Manager parameters](#) in the *AWS Systems Manager User Guide*.

Systems Manager parameter format in launch templates

To use a Systems Manager parameter in place of an AMI ID in a launch template, you must use one of the following formats when specifying the parameter in the launch template:

- `resolve:ssm:parameter-name`
- `resolve:ssm:parameter-name:version-number` – The version number itself is a default label
- `resolve:ssm:parameter-name:label`

Parameter versions

Systems Manager parameters are versioned resources. When you update a parameter, you create new, successive versions of the parameter. Systems Manager supports [parameter labels](#) that you can map to specific versions of a parameter.

For example, the golden-ami parameter can have three versions: 1, 2, and 3. You can create a parameter label `beta` that maps to version 2, and a parameter label `prod` that maps to version 3.

In a launch template, you can specify version 3 of the golden-ami parameter by using either of the following formats:

- `resolve:ssm:golden-ami:3`
- `resolve:ssm:golden-ami:prod`

Specifying the version or label is optional. If a version or label is not specified, the latest version of the parameter is used.

Specify a Systems Manager parameter in a launch template

You can specify a Systems Manager parameter in a launch template instead of an AMI ID when you create a launch template or a new version of a launch template.

Console

To specify a Systems Manager parameter in a launch template

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.
3. For **Launch template name**, enter a descriptive name for the launch template.
4. Under **Application and OS Images (Amazon Machine Image)**, choose **Browse more AMIs**.
5. Choose the arrow button to the right of the search bar, and then choose **Specify custom value/Systems Manager parameter**.
6. In the **Specify custom value or Systems Manager parameter** dialog box, do the following:
 - a. For **AMI ID or Systems Manager parameter string**, enter the Systems Manager parameter name using one of the following formats:
 - `resolve:ssm:parameter-name`
 - `resolvessm:parameter-name:version-number`
 - `resolvessm:parameter-name:label`
 - b. Choose **Save**.
7. Specify any other launch template parameters as needed, and then choose **Create launch template**.

For more information, see [Create a new launch template using parameters you define \(p. 570\)](#).

AWS CLI

To specify a Systems Manager parameter in a launch template

- Use the [create-launch-template](#) command to create the launch template. To specify the AMI to use, enter the Systems Manager parameter name using one of the following formats:
 - `resolve:ssm:parameter-name`
 - `resolvessm:parameter-name:version-number`
 - `resolvessm:parameter-name:label`

The following example creates a launch template that specifies the following:

- A name for the launch template (`TemplateForWebServer`)
- A tag for the launch template (`purpose=production`)
- The data for the instance configuration, specified in a JSON file:
 - The AMI to use (`resolve:ssm:golden-ami`)
 - The instance type to launch (`m5.4xlarge`)
 - A tag for the instance (`Name=webserver`)

```
aws ec2 create-launch-template \
--launch-template-name TemplateForWebServer \
--tag-specifications 'ResourceType=launch-
template,Tags=[{Key=purpose,Value=production}]' \
```

```
--launch-template-data file://template-data.json
```

The following is an example JSON file that contains the launch template data for the instance configuration. The value for ImageId is the Systems Manager parameter name, entered in the required format `resolve:ssm:golden-ami`.

```
{"LaunchTemplateData": {  
    "ImageId": "resolve:ssm:golden-ami",  
    "InstanceType": "m5.4xlarge",  
    "TagSpecifications": [{  
        "ResourceType": "instance",  
        "Tags": [{  
            "Key": "Name",  
            "Value": "webserver"  
        }]  
    }]  
}
```

Limitations

- Currently, EC2 Fleets and Spot Fleets do not support using a launch template that has a Systems Manager parameter specified in place of an AMI ID. For EC2 Fleets and Spot Fleets, if you specify an AMI in the launch template, you must specify the AMI ID.
- There are also limitations for Auto Scaling groups that use a launch template that specifies a Systems Manager parameter instead of an AMI ID. For more information, see [Limitations](#) in the *Amazon EC2 Auto Scaling User Guide*.

Modify a launch template (manage launch template versions)

Launch templates are immutable; after you create a launch template, you can't modify it. Instead, you can create a new version of the launch template that includes any changes you require.

You can create different versions of a launch template, set the default version, describe a launch template version, and delete versions that you no longer require.

Tasks

- [Create a launch template version \(p. 583\)](#)
- [Set the default launch template version \(p. 584\)](#)
- [Describe a launch template version \(p. 584\)](#)
- [Delete a launch template version \(p. 585\)](#)

Create a launch template version

When you create a launch template version, you can specify new launch parameters or use an existing version as the base for the new version. For more information about the launch parameters, see [Create a launch template \(p. 570\)](#).

Console

To create a launch template version

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.

3. Select a launch template, and then choose **Actions, Modify template (Create new version)**.
4. For **Template version description**, enter a description for this version of the launch template.
5. (Optional) Expand **Source template** and select a version of the launch template to use as a base for the new launch template version. The new launch template version inherits the launch parameters from this launch template version.
6. Modify the launch parameters as required, and choose **Create launch template**.

AWS CLI

To create a launch template version

- Use the [create-launch-template-version](#) command. You can specify a source version on which to base the new version. The new version inherits the launch parameters from this version, and you can override parameters using `--launch-template-data`. The following example creates a new version based on version 1 of the launch template and specifies a different AMI ID.

```
aws ec2 create-launch-template-version \
--launch-template-id lt-0abcd290751193123 \
--version-description WebVersion2 \
--source-version 1 \
--launch-template-data "ImageId=ami-c998b6b2"
```

Set the default launch template version

You can set the default version for the launch template. When you launch an instance from a launch template and do not specify a version, the instance is launched using the parameters of the default version.

Console

To set the default launch template version

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Set default version**.
4. For **Template version**, select the version number to set as the default version and choose **Set as default version**.

AWS CLI

To set the default launch template version

- Use the [modify-launch-template](#) command and specify the version that you want to set as the default.

```
aws ec2 modify-launch-template \
--launch-template-id lt-0abcd290751193123 \
--default-version 2
```

Describe a launch template version

Using the console, you can view all the versions of the selected launch template, or get a list of the launch templates whose latest or default version matches a specific version number. Using the AWS CLI,

you can describe all versions, individual versions, or a range of versions of a specified launch template. You can also describe all the latest versions or all the default versions of all the launch templates in your account.

Console

To describe a launch template version

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. You can view a version of a specific launch template, or get a list of the launch templates whose latest or default version matches a specific version number.
 - To view a version of a launch template: Select the launch template. On the **Versions** tab, from **Version**, select a version to view its details.
 - To get a list of all the launch templates whose latest version matches a specific version number: From the search bar, choose **Latest version**, and then choose a version number.
 - To get a list of all the launch templates whose default version matches a specific version number: From the search bar, choose **Default version**, and then choose a version number.

AWS CLI

To describe a launch template version

- Use the [describe-launch-template-versions](#) command and specify the version numbers. In the following example, versions **1** and **3** are specified.

```
aws ec2 describe-launch-template-versions \
--launch-template-id lt-0abcd290751193123 \
--versions 1 3
```

To describe all the latest and default launch template versions in your account

- Use the [describe-launch-template-versions](#) command and specify **\$Latest**, **\$Default**, or both. You must omit the launch template ID and name in the call. You cannot specify version numbers.

```
aws ec2 describe-launch-template-versions \
--versions "$Latest,$Default"
```

Delete a launch template version

If you no longer require a launch template version, you can delete it.

Considerations

- You can't replace the version number after you delete it.
- You can't delete the default version of the launch template; you must first assign a different version as the default. If the default version is the only version for the launch template, you must [delete the entire launch template \(p. 586\)](#).
- When using the console, you can delete one launch template version at a time. When using the AWS CLI, you can delete up to 200 launch template versions in a single request. To delete more than 200 versions in a single request, you can [delete the launch template \(p. 586\)](#), which also deletes all of its versions.

Console

To delete a launch template version

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Delete template version**.
4. Select the version to delete and choose **Delete**.

AWS CLI

To delete a launch template version

- Use the [delete-launch-template-versions](#) command and specify the version numbers to delete. You can specify up to 200 launch template versions to delete in a single request.

```
aws ec2 delete-launch-template-versions \
--launch-template-id lt-0abcd290751193123 \
--versions 1
```

Delete a launch template

If you no longer require a launch template, you can delete it. Deleting a launch template deletes all of its versions. To delete a specific version of a launch template, see [Delete a launch template version \(p. 585\)](#).

When you delete a launch template, it doesn't affect any instances that you've launched from the launch template.

Console

To delete a launch template

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Delete template**.
4. Enter **Delete** to confirm deletion, and then choose **Delete**.

AWS CLI

To delete a launch template

- Use the [delete-launch-template](#) (AWS CLI) command and specify the launch template.

```
aws ec2 delete-launch-template --launch-template-id lt-01238c059e3466abc
```

Launch instances from a launch template

Launch templates are supported by several instance launch services. This topic describes how to use a launch template when launching an instance using the EC2 launch instance wizard, Amazon EC2 Auto Scaling, EC2 Fleet, and Spot Fleet.

Topics

- [Launch an instance from a launch template \(p. 587\)](#)
- [Use launch templates with Amazon EC2 Auto Scaling \(p. 589\)](#)
- [Use launch templates with EC2 Fleet \(p. 590\)](#)
- [Use launch templates with Spot Fleet \(p. 590\)](#)

Launch an instance from a launch template

You can use the parameters contained in a launch template to launch an instance. You have the option to override or add launch parameters before you launch the instance.

Instances that are launched using a launch template are automatically assigned two tags with the keys `aws:ec2launchtemplate:id` and `aws:ec2launchtemplate:version`. You cannot remove or edit these tags.

Console

To launch an instance from a launch template using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Launch instance from template**.
4. For **Source template version**, select the launch template version to use.
5. For **Number of instances**, specify the number of instances to launch.
6. (Optional) You can override or add launch template parameters by changing and adding parameters in the **Instance details** section.
7. Choose **Launch instance from template**.

AWS CLI

To launch an instance from a launch template using the AWS CLI

- Use the [run-instances](#) command and specify the `--launch-template` parameter. Optionally specify the launch template version to use. If you don't specify the version, the default version is used.

```
aws ec2 run-instances \
    --launch-template LaunchTemplateId=lt-0abcd290751193123,Version=1
```

- To override a launch template parameter, specify the parameter in the [run-instances](#) command. The following example overrides the instance type that's specified in the launch template (if any).

```
aws ec2 run-instances \
    --launch-template LaunchTemplateId=lt-0abcd290751193123 \
    --instance-type t2.small
```

- If you specify a nested parameter that's part of a complex structure, the instance is launched using the complex structure as specified in the launch template plus any additional nested parameters that you specify.

In the following example, the instance is launched with the tag `Owner=TeamA` as well as any other tags that are specified in the launch template. If the launch template has an existing tag with a key of `Owner`, the value is replaced with `TeamA`.

```
aws ec2 run-instances \
--launch-template LaunchTemplateId=lt-0abcd290751193123 \
--tag-specifications "ResourceType=instance,Tags=[{Key=Owner,Value=TeamA}]"
```

In the following example, the instance is launched with a volume with the device name `/dev/xvdb` as well as any other block device mappings that are specified in the launch template. If the launch template has an existing volume defined for `/dev/xvdb`, its values are replaced with the specified values.

```
aws ec2 run-instances \
--launch-template LaunchTemplateId=lt-0abcd290751193123 \
--block-device-mappings "DeviceName=/dev/xvdb,Ebs={VolumeSize=20,VolumeType=gp2}"
```

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 2114\)](#).

PowerShell

To launch an instance from a launch template using the AWS Tools for PowerShell

- Use the [New-EC2Instance](#) command and specify the `-LaunchTemplate` parameter. Optionally specify the launch template version to use. If you don't specify the version, the default version is used.

```
Import-Module AWS.Tools.EC2
New-EC2Instance ` 
    -LaunchTemplate (
        New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -Property
    @{
        LaunchTemplateId = 'lt-0abcd290751193123';
        Version         = '4'
    }
)
```

- To override a launch template parameter, specify the parameter in the [New-EC2Instance](#) command. The following example overrides the instance type that's specified in the launch template (if any).

```
Import-Module AWS.Tools.EC2
New-EC2Instance ` 
    -InstanceType t4g.small ` 
    -LaunchTemplate (
        New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -Property
    @{
        LaunchTemplateId = 'lt-0abcd290751193123';
        Version         = '4'
    }
)
```

- If you specify a nested parameter that's part of a complex structure, the instance is launched using the complex structure as specified in the launch template plus any additional nested parameters that you specify.

In the following example, the instance is launched with the tag `Owner=TeamA` as well as any other tags that are specified in the launch template. If the launch template has an existing tag with a key of `Owner`, the value is replaced with `TeamA`.

```
Import-Module AWS.Tools.EC2
```

```
New-EC2Instance ` 
    -InstanceType t4g.small ` 
    -LaunchTemplate ( 
        New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -Property @{ 
            LaunchTemplateId = 'lt-0abcd290751193123'; 
            Version         = '4' 
        } 
    ) ` 
    -TagSpecification ( 
        New-Object -TypeName Amazon.EC2.Model.TagSpecification -Property @{ 
            ResourceType = 'instance'; 
            Tags          = @(
                @{key = "Owner"; value = "TeamA"}, 
                @{key = "Department"; value = "Operations"} 
            ) 
        } 
    ) 
)
```

In the following example, the instance is launched with a volume with the device name `/dev/xvdb` as well as any other block device mappings that are specified in the launch template. If the launch template has an existing volume defined for `/dev/xvdb`, its values are replaced with the specified values.

```
Import-Module AWS.Tools.EC2
New-EC2Instance ` 
    -InstanceType t4g.small ` 
    -LaunchTemplate ( 
        New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -Property @{ 
            LaunchTemplateId = 'lt-0abcd290751193123'; 
            Version         = '4' 
        } 
    ) ` 
    -BlockDeviceMapping ( 
        New-Object -TypeName Amazon.EC2.Model.BlockDeviceMapping -Property @{ 
            DeviceName = '/dev/xvdb'; 
            EBS        = ( 
                New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice -Property @{ 
                    VolumeSize = 25; 
                    VolumeType = 'gp3' 
                } 
            ) 
        } 
    ) 
)
```

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 2114\)](#).

Use launch templates with Amazon EC2 Auto Scaling

You can create an Auto Scaling group and specify a launch template to use for the group. When Amazon EC2 Auto Scaling launches instances in the Auto Scaling group, it uses the launch parameters defined in the associated launch template. For more information, see [Creating an Auto Scaling Group Using a Launch Template](#) in the *Amazon EC2 Auto Scaling User Guide*.

Before you can create an Auto Scaling group using a launch template, you must create a launch template that includes the parameters required to launch an instance in an Auto Scaling group, such as the ID of the AMI. The console provides guidance to help you create a template that you can use with Auto Scaling.

To create a launch template to use with Auto Scaling using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Launch Templates**, and then choose **Create launch template**.
3. For **Launch template name**, enter a descriptive name for the launch template.
4. For **Template version description**, provide a brief description of this version of the launch template.
5. Under **Auto Scaling guidance**, select the check box to have Amazon EC2 provide guidance to help create a template to use with Auto Scaling.
6. Modify the launch parameters as required. Because you selected Auto Scaling guidance, some fields are required and some fields are not available. For considerations to keep in mind when creating a launch template, and for information about how to configure the launch parameters for Auto Scaling, see [Creating a launch template for an Auto Scaling group](#) in the *Amazon EC2 Auto Scaling User Guide*.
7. Choose **Create launch template**.
8. (Optional) To create an Auto Scaling group using this launch template, on the **Next steps** page, choose **Create Auto Scaling group**.

To create or update an Amazon EC2 Auto Scaling group with a launch template using the AWS CLI

- Use the [create-auto-scaling-group](#) or the [update-auto-scaling-group](#) command and specify the `--launch-template` parameter.

Use launch templates with EC2 Fleet

You can create an EC2 Fleet request and specify a launch template in the instance configuration. When Amazon EC2 fulfills the EC2 Fleet request, it uses the launch parameters defined in the associated launch template. You can override some of the parameters that are specified in the launch template.

For more information, see [Create an EC2 Fleet \(p. 1013\)](#).

To create an EC2 Fleet with a launch template using the AWS CLI

- Use the [create-fleet](#) command. Use the `--launch-template-configs` parameter to specify the launch template and any overrides for the launch template.

Use launch templates with Spot Fleet

You can create a Spot Fleet request and specify a launch template in the instance configuration. When Amazon EC2 fulfills the Spot Fleet request, it uses the launch parameters defined in the associated launch template. You can override some of the parameters that are specified in the launch template.

For more information, see [Create a Spot Fleet request \(p. 1058\)](#).

To create a Spot Fleet request with a launch template using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Spot Requests**.
3. Choose **Request Spot Instances**.
4. Under **Launch parameters**, choose **Use a launch template**.
5. For **Launch template**, choose a launch template, and then, from the field to the right, choose the launch template version.
6. Configure your Spot Fleet by selecting different options on this screen. For more information about the options, see [Create a Spot Fleet request using defined parameters \(console\) \(p. 1059\)](#).

- When you're ready to create your Spot Fleet, choose **Launch**.

To create a Spot Fleet request with a launch template using the AWS CLI

- Use the [request-spot-fleet](#) command. Use the LaunchTemplateConfigs parameter to specify the launch template and any overrides for the launch template.

Launch an instance using parameters from an existing instance

The Amazon EC2 console provides a **Launch more like this** option that enables you to use a current instance as a base for launching other instances. This option automatically populates the Amazon EC2 launch instance wizard with certain configuration details from the selected instance.

Note

The **Launch more like this** option does not clone your selected instance; it only replicates some configuration details. To create a copy of your instance, first create an AMI from it, then launch more instances from the AMI.

Alternatively, create a [launch template \(p. 567\)](#) to store the launch parameters for your instances.

The following configuration details are copied from the selected instance into the launch instance wizard:

- AMI ID
- Instance type
- Availability Zone, or the VPC and subnet in which the selected instance is located
- Public IPv4 address. If the selected instance currently has a public IPv4 address, the new instance receives a public IPv4 address - regardless of the selected instance's default public IPv4 address setting. For more information about public IPv4 addresses, see [Public IPv4 addresses \(p. 1236\)](#).
- Placement group, if applicable
- IAM role associated with the instance, if applicable
- Shutdown behavior setting (stop or terminate)
- Termination protection setting (true or false)
- CloudWatch monitoring (enabled or disabled)
- Amazon EBS-optimization setting (true or false)
- Tenancy setting, if launching into a VPC (shared or dedicated)
- Kernel ID and RAM disk ID, if applicable
- User data, if specified
- Tags associated with the instance, if applicable
- Security groups associated with the instance
- Association information. If the selected instance is associated with a configuration file, the same file is automatically associated with the new instance. If the configuration file includes a joined domain configuration, the new instance is joined to the same domain. For more information about joining a domain, see [Seamlessly Join a Windows EC2 Instance](#) in the *AWS Directory Service Administration Guide*.

The following configuration details are not copied from your selected instance. Instead, the wizard applies their default settings or behavior:

- Number of network interfaces: The default is one network interface, which is the primary network interface (eth0).
- Storage: The default storage configuration is determined by the AMI and the instance type.

To use your current instance as a template

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance you want to use, and then choose **Actions, Images and templates, Launch more like this**.
4. The launch instance wizard opens. You can make any necessary changes to the instance configuration by selecting different options on this screen.

When you are ready to launch your instance, choose **Launch instance**.

5. If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 2114\)](#).

Launch an AWS Marketplace instance

You can subscribe to an AWS Marketplace product and launch an instance from the product's AMI using the Amazon EC2 launch wizard. For more information about paid AMIs, see [Paid AMIs \(p. 147\)](#). To cancel your subscription after launch, you first have to terminate all instances running from it. For more information, see [Manage your AWS Marketplace subscriptions \(p. 150\)](#).

New console

To launch an instance from the AWS Marketplace using the launch wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the Amazon EC2 console dashboard, choose **Launch instance**.
3. (Optional) Under **Name and tags**, for **Name**, enter a descriptive name for your instance.
4. Under **Application and OS Images (Amazon Machine Image)**, choose **Browse more AMIs**, and then choose the **AWS Marketplace AMIs** tab. Find a suitable AMI by browsing the categories or using the search functionality. To choose a product, choose **Select**.
5. A dialog box opens with an overview of the product you've selected. You can view the pricing information, as well as any other information that the vendor has provided. When you're ready, choose **Continue**.

Note

You're not charged for using the product until you have launched an instance with the AMI. Take note of the pricing for each supported instance type when you select an instance type. Additional taxes might also apply to the product.

6. For **Instance type**, select an instance type for your instance. The instance type defines the hardware configuration and size of the instance to launch.
7. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one.
8. Under **Network settings, Firewall (security groups)**, take note of the new security group that was created according to the vendor's specifications for the product. The security group might include rules that allow all IPv4 addresses (0.0.0.0/0) access on SSH (port 22) on Linux or RDP (port 3389) on Windows. We recommend that you adjust these rules to allow only a specific address or range of addresses to access your instance over those ports.
9. You can use the other fields on the screen to configure your instance, add storage, and add tags. For information about the different options that you can configure, see [Launch an instance using defined parameters \(p. 554\)](#).
10. In the **Summary** panel, under **Software Image (AMI)**, check the details of the AMI from which you're about to launch the instance. Also check the other configuration details that you specified. When you're ready to launch your instance, choose **Launch instance**.

11. Depending on the product you've subscribed to, the instance might take a few minutes or more to launch. You are first subscribed to the product before your instance can launch. If there are any problems with your credit card details, you will be asked to update your account details. When the launch confirmation page displays, choose **View all instances** to go to the **Instances** page.

Note

You are charged the subscription price as long as your instance is in the `running` state, even if it is idle. If your instance is stopped, you might still be charged for storage.

12. When your instance is in the `running` state, you can connect to it. To do this, select your instance in the list, choose **Connect**, and choose a connection option. For more information about connecting to your instance, see [Connect to your Windows instance \(p. 626\)](#).

Important

Check the vendor's usage instructions carefully, as you might need to use a specific user name to connect to your instance. For information about accessing your subscription details, see [Manage your AWS Marketplace subscriptions \(p. 150\)](#).

13. If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see [Troubleshoot instance launch issues \(p. 2114\)](#).

Old console

To launch an instance from the AWS Marketplace using the launch wizard

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the Amazon EC2 dashboard, choose **Launch instance**.
3. On the **Choose an Amazon Machine Image (AMI)** page, choose the **AWS Marketplace** category on the left. Find a suitable AMI by browsing the categories, or using the search functionality. Choose **Select** to choose your product.
4. A dialog displays an overview of the product you've selected. You can view the pricing information, as well as any other information that the vendor has provided. When you're ready, choose **Continue**.

Note

You are not charged for using the product until you have launched an instance with the AMI. Take note of the pricing for each supported instance type, as you will be prompted to select an instance type on the next page of the wizard. Additional taxes may also apply to the product.

5. On the **Choose an Instance Type** page, select the hardware configuration and size of the instance to launch. When you're done, choose **Next: Configure Instance Details**.
6. On the next pages of the wizard, you can configure your instance, add storage, and add tags. For more information about the different options you can configure, see [Launch an instance using the old launch instance wizard \(p. 561\)](#). Choose **Next** until you reach the **Configure Security Group** page.

The wizard creates a new security group according to the vendor's specifications for the product. The security group may include rules that allow all IPv4 addresses (`0.0.0.0/0`) access on SSH (port 22) on Linux or RDP (port 3389) on Windows. We recommend that you adjust these rules to allow only a specific address or range of addresses to access your instance over those ports.

When you are ready, choose **Review and Launch**.

7. On the **Review Instance Launch** page, check the details of the AMI from which you're about to launch the instance, as well as the other configuration details you set up in the wizard. When you're ready, choose **Launch** to select or create a key pair, and launch your instance.
8. Depending on the product you've subscribed to, the instance may take a few minutes or more to launch. You are first subscribed to the product before your instance can launch. If there are any

problems with your credit card details, you will be asked to update your account details. When the launch confirmation page displays, choose **View Instances** to go to the Instances page.

Note

You are charged the subscription price as long as your instance is running, even if it is idle. If your instance is stopped, you may still be charged for storage.

9. When your instance is in the `running` state, you can connect to it. To do this, select your instance in the list and choose **Connect**. Follow the instructions in the dialog. For more information about connecting to your instance, see [Connect to your Windows instance \(p. 626\)](#).

Important

Check the vendor's usage instructions carefully, as you may need to use a specific user name to log in to the instance. For more information about accessing your subscription details, see [Manage your AWS Marketplace subscriptions \(p. 150\)](#).

10. If the instance fails to launch or the state immediately goes to `terminated` instead of `running`, see [Troubleshoot instance launch issues \(p. 2114\)](#).

Launch an AWS Marketplace AMI instance using the API and CLI

To launch instances from AWS Marketplace products using the API or command line tools, first ensure that you are subscribed to the product. You can then launch an instance with the product's AMI ID using the following methods:

Method	Documentation
AWS CLI	Use the run-instances command, or see the following topic for more information: Launching an Instance .
AWS Tools for Windows PowerShell	Use the New-EC2Instance command, or see the following topic for more information: Launch an Amazon EC2 Instance Using Windows PowerShell
Query API	Use the RunInstances request.

Stop and start your instance

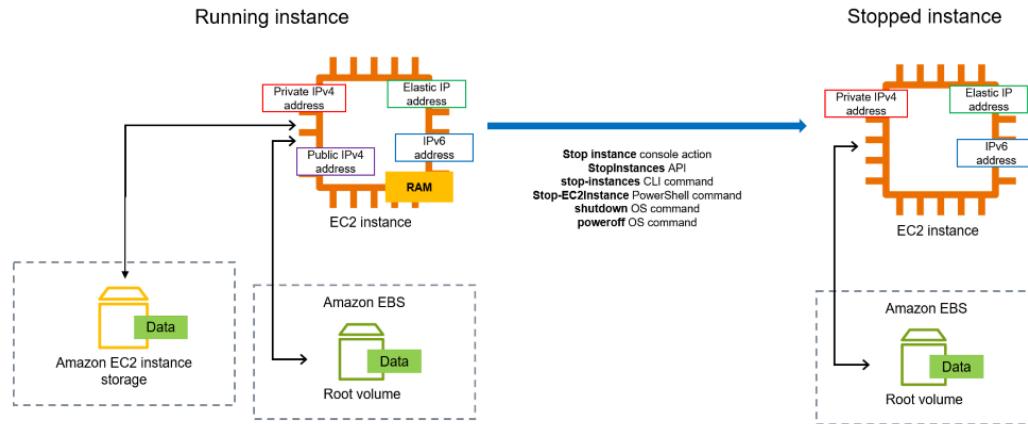

You can stop and start your instance if it has an Amazon EBS volume as its root device. The instance retains its instance ID, but can be modified as described in the [Modify a stopped instance \(p. 598\)](#) section. When you stop an instance, the instance shuts down. When you start an instance, the instance is typically migrated to a new underlying host computer and assigned a new public IPv4 address.

When you stop an instance, it is not deleted. If you decide that you no longer need an instance, you can terminate it. For more information, see [Terminate your instance \(p. 615\)](#). If you want to hibernate an instance to save the contents from the instance memory (RAM), see [Hibernate your On-Demand Windows instance \(p. 602\)](#). For distinctions between instance lifecycle actions, see [Differences between reboot, stop, hibernate, and terminate \(p. 549\)](#).

AWS can schedule events for your instances, such as reboot, stop/start, or retirement. For information about the type of scheduled events that are managed by AWS, and how to view and receive notifications about scheduled events, see [Scheduled events for your instances \(p. 1160\)](#).

The following diagram shows what is lost and what persists when an Amazon EC2 instance is stopped. When an instance stops, it loses any attached instance store volumes and the data stored on those volumes, the data stored on the instance RAM, and the assigned public IPv4 address if an Elastic IP

address is not associated with the instance. An instance retains assigned private IPv4 addresses, Elastic IP addresses associated with the instance, any IPv6 addresses, and any attached Amazon EBS volumes and the data on those volumes.

Costs related to starting and stopping an instance

The following costs are associated with stopping and starting an instance.

Stopping — As soon as the state of an instance changes to shutting-down or terminated, charges are no longer incurred for the instance. You are not charged for usage or data transfer fees for a stopped instance. Charges are incurred to store Amazon EBS storage volumes.

Starting — Each time you start a stopped instance, you are charged for a minimum of one minute of usage. After one minute, you are charged for only the seconds you use. For example, if you run an instance for 20 seconds and then stop it, you are charged for a minute of usage. If you run an instance for 3 minutes and 40 seconds, you are charged for 3 minutes and 40 seconds of usage.

Find all running and stopped instances

You can find all of your running and stopped instances across all AWS Regions on a single page using [Amazon EC2 Global View](#). This capability is especially useful for taking inventory and finding forgotten instances. For information about how to use Global View, see [List and filter resources across Regions using Amazon EC2 Global View \(p. 2083\)](#).

Prerequisites for stopping an instance

You can stop an Amazon EBS-backed instance. Instances backed by an instance store volume do not support the **Stop** action. To better understand the differences between the two volume types, see [Storage \(p. 1701\)](#).

To verify the root device type of an instance, you can use the Amazon EC2 console or the AWS CLI.

Amazon EC2 console

In the Amazon EC2 console, open the **Instances** pane and select an instance. The **Root device type** is listed on the **Storage** tab, under **Root device details**.

AWS CLI

You can verify the root device type of an instance by running the `describe-instances` AWS CLI command and checking the output for `RootDeviceType: ebs` or `instance-store`. For more information, see [describe-instances](#) in the *AWS CLI Command Reference*.

Manually stop and start an instances

You can stop and start your Amazon EBS-backed instance using the console or the command line.

Warning

When you stop an instance, the data on any attached instance store volumes is erased. Before you stop an instance, verify that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3. Instances *backed by an instance store volume* do not support the **Stop** action.

Console

To stop and start an Amazon EBS-backed instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances** and select the instance.
3. Choose **Instance state, Stop instance**. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
4. When prompted for confirmation, choose **Stop**. It can take a few minutes for the instance to stop.
5. (Optional) While your instance is stopped, you can modify certain instance attributes. For more information, see [Modify a stopped instance \(p. 598\)](#).
6. To start a stopped instance, select the instance, and choose **Instance state, Start instance**.
7. It can take a few minutes for the instance to enter the `running` state.

Command line

To stop and start an Amazon EBS-backed instance

Run one of the following commands:

- **AWS CLI**—[stop-instances](#) and [start-instances](#).
- **AWS Tools for PowerShell**—[Stop-EC2Instance](#) and [Start-EC2Instance](#).
- **OS commands**—You can initiate a shutdown using the `shutdown` or `poweroff` commands. When you use an OS command, the instance stops by default. You can change this behavior so that it terminates instead. For more information, see [Change the instance initiated shutdown behavior \(p. 619\)](#).

Automatically stop and start your instances

You can automate stopping and starting instances with the following services:

Instance Scheduler on AWS

You can use Instance Scheduler on AWS to automate the starting and stopping of EC2 instances. For more information, see [How do I use Instance Scheduler with CloudFormation to schedule EC2 instances?](#) Note that [additional charges apply](#).

AWS Lambda and an Amazon EventBridge rule

You can use Lambda and an EventBridge rule to stop and start your instances on a schedule. For more information, see [How do I stop and start Amazon EC2 instances at regular intervals using Lambda?](#)

Amazon EC2 Auto Scaling

To ensure you have the correct number of Amazon EC2 instances available to handle the load for an application, create Auto Scaling groups. Amazon EC2 Auto Scaling ensures that your application always has the right capacity to handle the traffic demand, and saves costs by launching instances only when they are needed. Note that Amazon EC2 Auto Scaling terminates, rather than stops, unneeded instances. To set up Auto Scaling groups, see [Get started with Amazon EC2 Auto Scaling](#).

What happens when you stop an instance

When you stop an instance, changes are registered at the OS level of the instance, some system resources are lost, and some persist.

When you stop an instance, the following is *registered at the OS level*:

- The API request sends a button press event to the guest.
- Various system services are stopped as a result of the button press event. Graceful shutdown is triggered by the ACPI shutdown button press event from the hypervisor.
- ACPI shutdown is initiated.
- The instance shuts down when the graceful shutdown process exits. There is no configurable OS shutdown time.
- If the instance OS does not cleanly shut down within a few minutes, a hard shutdown is performed.
- The instance stops running.
- The instance status changes to stopping and then stopped.
- **[Auto Scaling]** If your instance is in an Auto Scaling group, when the instance is in any Amazon EC2 state other than `running`, or if its status for the status checks becomes `impaired`, Amazon EC2 Auto Scaling considers the instance to be unhealthy and replaces it. For more information, see [Health checks for Auto Scaling instances](#) in the *Amazon EC2 Auto Scaling User Guide*.
- When you stop and start a Windows instance, the launch agent performs tasks on the instance, such as changing the drive letters for any attached Amazon EBS volumes. For more information about these defaults and how you can change them, see [Configure a Windows instance using EC2Launch v2](#).

When you stop an instance, the following is *lost*:

- Data stored on the RAM.
- Data stored on the instance store volumes.
- The public IPv4 address that Amazon EC2 automatically assigned to the instance upon launch or start. To retain a public IPv4 address that never changes, you can associate an [Elastic IP address \(p. 1269\)](#) with your instance.

When you stop an instance, the following persists:

- Any attached Amazon EBS volumes.
- Data stored on the attached Amazon EBS volumes.
- Private IPv4 addresses.
- IPv6 addresses.
- Elastic IP addresses associated with the instance. Note that when the instance is stopped, you are [charged for the associated Elastic IP addresses \(p. 1269\)](#).

For information about what happens when you stop a Mac instance, see [Stop and terminate your Mac instance](#).

What happens when you start an instance

When you start an instance, changes are registered at the instance level.

When you start an EC2 instance, the following occurs:

- In most cases, the instance is migrated to a new underlying host computer (though in some cases, such as when an instance is allocated to a host in a [Dedicated Host](#) configuration, it remains on the current host).
- Amazon EC2 assigns a new public IPv4 address to the instance if the instance is configured to receive a public IPv4 address. To retain a public IPv4 address that never changes, you can associate an [Elastic IP address \(p. 1269\)](#) with your instance.

Modify a stopped instance

When an instance is stopped, you can treat its root volume like any other volume, and modify it (for example, repair file system problems or update software).

You can modify the following attributes of an instance only when it is stopped:

- Instance type
- User data
- Kernel
- RAM disk

If you try to modify these attributes while the instance is running, Amazon EC2 returns the `IncorrectInstanceState` error.

You can change the following attributes of a stopped instance using the Amazon EC2 console or the AWS CLI:

- Instance type
- User data
- EBS-optimization

Modification of the following attributes using the Amazon EC2 console is not supported:

- `DeleteOnTermination`
- Kernel
- RAM disk

Modify an instance attribute

You can modify an instance attribute using the Amazon EC2 console or the command line.

Console

To modify the following in the AWS Management Console	See the following resource
Instance type	Change the instance type (p. 344)
User data	Run commands on your Windows instance at launch
EBS–optimization	Modifying EBS–Optimization (p. 1964)
The DeleteOnTermination attribute of the root volume	Update the block device mapping of a running instance (p. 2033) . You are not required to stop the instance to change this attribute.

Command line

Modify an instance attribute using the command line

You can use the following commands to modify instance attributes. For more information about these command line interfaces see [Access Amazon EC2 \(p. 5\)](#).

- [modify-instance-attribute](#) (AWS CLI)
- [Edit-EC2InstanceAttribute](#) (AWS Tools for PowerShell)

Modify the root volume of an instance

You can modify the root volume of an instance by performing the following steps.

1. Detach the volume from the stopped instance.
2. Attach the volume to a running instance.
3. Modify the volume.
4. Detach the volume from the running instance.
5. Reattach the volume to the stopped instance.

Make sure that you reattach the root volume using the storage device name specified as the root device in the block device mapping for the instance. For detailed steps on how to detach and attach a volume to an instance, see [Detach an Amazon EBS volume from a Windows instance \(p. 1752\)](#) and [Attach an Amazon EBS volume to an instance \(p. 1729\)](#). For more help with specifying block device mappings, see [Block device mappings \(p. 2026\)](#).

Enable stop protection

To prevent an instance from being accidentally stopped, you can enable stop protection for the instance. Stop protection also protects your instance from accidental termination.

The `DisableApiStop` attribute of the Amazon EC2 [ModifyInstanceAttribute](#) API controls whether the instance can be stopped. This attribute can be set using the Amazon EC2 console, the AWS CLI, or the Amazon EC2 API. You can set the value of this attribute when you launch the instance, while the instance is running, or while the instance is stopped.

Important

Setting the `DisableApiStop` attribute of the Amazon EC2 [ModifyInstanceAttribute](#) API action does not prevent you from accidentally stopping an instance when you initiate a shutdown from the instance using the OS **shutdown** or **poweroff** commands.

Stop protection considerations

- Enabling stop protection does not prevent AWS from stopping the instance when there are [scheduled events \(p. 1160\)](#) to stop the instance.
- Enabling stop protection does not prevent Amazon EC2 Auto Scaling from terminating an instance when the instance is unhealthy or during scale-in events. You can control whether an Auto Scaling group can terminate a particular instance when scaling in by using [instance scale-in protection](#).
- Stop protection not only prevents your instance from being accidentally stopped, but also from accidental termination when using the console, AWS CLI, or API. However, it does not automatically set the `DisableApiTermination` attribute. Note that when the `DisableApiStop` attribute is set to `false`, the `DisableApiTermination` attribute setting determines whether the instance can be terminated using the console, AWS CLI, or API. For more information see [Terminate your instance \(p. 615\)](#).
- You cannot enable stop protection for instance store-backed instances.
- You cannot enable stop protection for Spot Instances.
- The Amazon EC2 API follows an eventual consistency model when you enable or disable stop protection. This means that the result of running commands to set the stop protection attribute might not be immediately visible to all subsequent commands you run. For more information, see [Eventual consistency](#) in the *Amazon EC2 API Reference*.

Stop protection actions

- [Enable stop protection for an instance at launch \(p. 600\)](#)
- [Enable stop protection for a running or stopped instance \(p. 601\)](#)
- [Disable stop protection for a running or stopped instance \(p. 601\)](#)

Enable stop protection for an instance at launch

You can enable stop protection for an instance when launching the instance using one of the following methods.

Console

To enable stop protection for an instance at launch

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the dashboard, choose **Launch instance**.
3. Configure your instance in the [new launch instance wizard \(p. 552\)](#).
4. In the wizard, enable stop protection by choosing **Enable** for **Stop protection** under **Advanced details**.

AWS CLI

To enable stop protection for an instance at launch

Use the [run-instances](#) AWS CLI command to launch the instance, and specify the `disable-api-stop` parameter.

```
aws ec2 run-instances \
```

```
--image-id ami-a1b2c3d4e5example \
--instance-type t3.micro \
--key-name MyKeyPair \
--disable-api-stop \
...
```

Enable stop protection for a running or stopped instance

You can enable stop protection for an instance while the instance is running or stopped using one of the following methods.

Console

To enable stop protection for a running or stopped instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**.
3. Select the instance, and then choose **Actions>Instance settings>Change stop protection**.
4. Select the **Enable** check box, and then choose **Save**.

AWS CLI

To enable stop protection for a running or stopped instance

Use the [modify-instance-attribute](#) AWS CLI command and specify the `disable-api-stop` parameter.

```
aws ec2 modify-instance-attribute \
--instance-id i-1234567890abcdef0 \
--disable-api-stop
```

Disable stop protection for a running or stopped instance

You can disable stop protection for a running or stopped instance using one of the following methods.

Console

To disable stop protection for a running or stopped instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances**.
3. Select the instance, and then choose **Actions, Instance settings, Change stop protection**.
4. Clear the **Enable** check box, and then choose **Save**.

AWS CLI

To disable stop protection for a running or stopped instance

Use the [modify-instance-attribute](#) AWS CLI command and specify the `no-disable-api-stop` parameter.

```
aws ec2 modify-instance-attribute \
--instance-id i-1234567890abcdef0 \
--no-disable-api-stop
```

Test application response to stop and start

You can use AWS Fault Injection Simulator to test how your application responds when your instance is stopped and started. For more information, see the [AWS Fault Injection Simulator User Guide](#).

Troubleshoot stopping your instance

If you stopped an Amazon EBS-backed instance and it appears "stuck" in the stopping state, you can forcibly stop it. For more information, see [Troubleshoot stopping your instance \(p. 2145\)](#).

Hibernate your On-Demand Windows instance

When you hibernate an instance, Amazon EC2 signals the operating system to perform hibernation (suspend-to-disk). Hibernation saves the contents from the instance memory (RAM) to your Amazon Elastic Block Store (Amazon EBS) root volume. Amazon EC2 persists the instance's EBS root volume and any attached EBS data volumes. When you start your instance:

- The EBS root volume is restored to its previous state
- The RAM contents are reloaded
- The processes that were previously running on the instance are resumed
- Previously attached data volumes are reattached and the instance retains its instance ID

You can hibernate an instance only if it's [enabled for hibernation \(p. 606\)](#) and it meets the [hibernation prerequisites \(p. 603\)](#).

If an instance or application takes a long time to bootstrap and build a memory footprint in order to become fully productive, you can use hibernation to pre-warm the instance. To pre-warm the instance, you:

1. Launch it with hibernation enabled.
2. Bring it to a desired state.
3. Hibernate it so that it's ready to be resumed to the desired state whenever needed.

You're not charged for instance usage for a hibernated instance when it is in the stopped state or for data transfer when the contents of the RAM are transferred to the EBS root volume. You are charged for storage of any EBS volumes, including storage for the RAM contents.

If you no longer need an instance, you can terminate it at any time, including when it is in a stopped (hibernated) state. For more information, see [Terminate your instance \(p. 615\)](#).

Note

For information about using hibernation on Linux instances, see [Hibernate your Linux instance in the Amazon EC2 User Guide for Linux Instances](#).

This topic describes how to hibernate On-Demand Instances (including those that may be covered by a Reserved Instance or a Capacity Reservation). For information about hibernating Spot Instances, see [Hibernate interrupted Spot Instances \(p. 435\)](#).

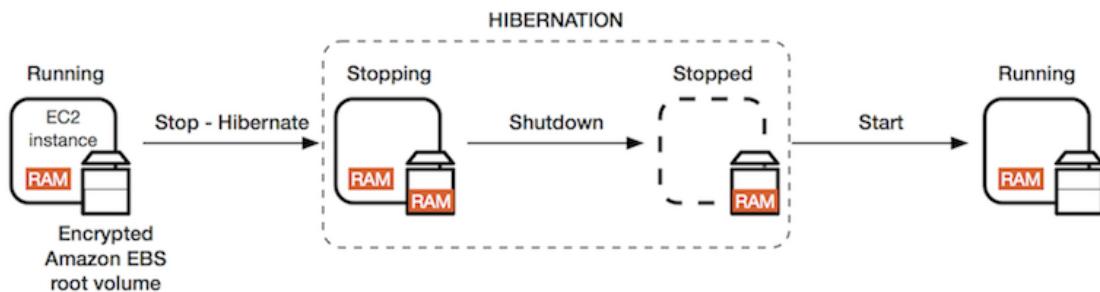

Contents

- [Overview of hibernation \(p. 603\)](#)
- [Hibernation prerequisites \(p. 603\)](#)
- [Limitations \(p. 605\)](#)
- [Enable hibernation for an instance \(p. 606\)](#)
- [Hibernate an instance \(p. 609\)](#)
- [Start a hibernated instance \(p. 611\)](#)

- [Troubleshoot hibernation \(p. 611\)](#)

Overview of hibernation

The following diagram shows a basic overview of the hibernation process.

When you hibernate a running instance, the following happens:

- When you initiate hibernation, the instance moves to the stopping state. Amazon EC2 signals the operating system to perform hibernation (suspend-to-disk). The hibernation freezes all of the processes, saves the contents of the RAM to the EBS root volume, and then performs a regular shutdown.
- After the shutdown is complete, the instance moves to the stopped state.
- Any EBS volumes remain attached to the instance, and their data persists, including the saved contents of the RAM.
- Any Amazon EC2 instance store volumes remain attached to the instance, but the data on the instance store volumes is lost.
- In most cases, the instance is migrated to a new underlying host computer when it's started. This is also what happens when you stop and start an instance.
- When you start the instance, the instance boots up and the operating system reads in the contents of the RAM from the EBS root volume, before unfreezing processes to resume its state.
- The instance retains its private IPv4 addresses and any IPv6 addresses. When you start the instance, the instance continues to retain its private IPv4 addresses and any IPv6 addresses.
- Amazon EC2 releases the public IPv4 address. When you start the instance, Amazon EC2 assigns a new public IPv4 address to the instance.
- The instance retains its associated Elastic IP addresses. You're charged for any Elastic IP addresses that are associated with a hibernated instance.

For information about how hibernation differs from reboot, stop, and terminate, see [Differences between reboot, stop, hibernate, and terminate \(p. 549\)](#).

Hibernation prerequisites

To hibernate an On-Demand Instance, the following prerequisites must be in place:

- [Supported Windows AMIs \(p. 604\)](#)
- [Supported instance families \(p. 604\)](#)
- [Instance size \(p. 604\)](#)
- [Instance RAM size \(p. 604\)](#)
- [Root volume type \(p. 605\)](#)
- [EBS root volume size \(p. 605\)](#)

- [Supported EBS volume types \(p. 605\)](#)
- [EBS root volume encryption \(p. 605\)](#)
- [Enable hibernation at launch \(p. 605\)](#)
- [Purchasing options \(p. 605\)](#)

Supported Windows AMIs

Must be an HVM AMI that supports hibernation:

- Windows Server 2012 AMI released 2019.09.11 or later
- Windows Server 2012 R2 AMI released 2019.09.11 or later
- Windows Server 2016 AMI released 2019.09.11 or later
- Windows Server 2019 AMI released 2019.09.11 or later

For information about the supported Linux AMIs, see [Supported Linux AMIs](#) in the *Amazon EC2 User Guide for Linux Instances*.

Supported instance families

- General purpose: M3, M4, M5, M5a, M5ad, M5d, M6i, M6id, M7i, M7i-flex, T2, T3, and T3a
- Compute optimized: C3, C4, C5, C5d, C6i, and C6id
- Memory optimized: R3, R4, R5, R5a, R5ad, and R5d
- Storage optimized: I3, and I3en

Note that for hibernating a T3 or T3a instance, we recommend at least 1 GB of RAM.

To see the available instance types that support hibernation in a specific Region

The available instance types vary by Region. To see the available instance types that support hibernation in a Region, use the [describe-instance-types](#) command with the --region parameter. Include the --filters parameter to scope the results to the instance types that support hibernation and the --query parameter to scope the output to the value of InstanceType.

```
aws ec2 describe-instance-types --filters Name=hibernation-supported,Values=true --query "InstanceTypes[*].[InstanceType]" --output text | sort
```

Example output

```
c3.2xlarge
c3.4xlarge
c3.8xlarge
c3.large
c3.xlarge
c4.2xlarge
c4.4xlarge
c4.8xlarge
...
```

Instance size

Not supported for bare metal instances.

Instance RAM size

Can be up to 16 GB.

Note that for hibernating a T3 or T3a instance, we recommend at least 1 GB of RAM.

Root volume type

Must be an EBS volume, not an instance store volume.

EBS root volume size

Must be large enough to store the RAM contents and accommodate your expected usage, for example, OS or applications. If you enable hibernation, space is allocated on the root volume at launch to store the RAM.

Supported EBS volume types

- General Purpose SSD (gp2 and gp3)
- Provisioned IOPS SSD (io1 and io2)

If you choose a Provisioned IOPS SSD volume type, you must provision the EBS volume with the appropriate IOPS to achieve optimum performance for hibernation. For more information, see [Amazon EBS volume types \(p. 1707\)](#).

EBS root volume encryption

To use hibernation, the root volume must be encrypted to ensure the protection of sensitive content that is in memory at the time of hibernation. When RAM data is moved to the EBS root volume, it is always encrypted. Encryption of the root volume is enforced at instance launch.

Use one of the following three options to ensure that the root volume is an encrypted EBS volume:

- **EBS encryption by default** – You can enable EBS encryption by default to ensure that all new EBS volumes created in your AWS account are encrypted. This way, you can enable hibernation for your instances without specifying encryption intent at instance launch. For more information, see [Encryption by default \(p. 1925\)](#).
- **EBS "single-step" encryption** – You can launch encrypted EBS-backed EC2 instances from an unencrypted AMI and also enable hibernation at the same time. For more information, see [Use encryption with EBS-backed AMIs \(p. 193\)](#).
- **Encrypted AMI** – You can enable EBS encryption by using an encrypted AMI to launch your instance. If your AMI does not have an encrypted root snapshot, you can copy it to a new AMI and request encryption. For more information, see [Encrypt an unencrypted image during copy \(p. 196\)](#) and [Copy an AMI \(p. 168\)](#).

Enable hibernation at launch

You cannot enable hibernation on an existing instance (running or stopped). For more information, see [Enable hibernation for an instance \(p. 606\)](#).

Purchasing options

This feature is available for On-Demand Instances, including those that have a Reserved Instance billing discount applied to them. It is not available for Spot Instances. For information about hibernating a Spot Instance, see [Hibernate interrupted Spot Instances \(p. 435\)](#).

Limitations

- When you hibernate an instance, the data on any instance store volumes is lost.

- You can't hibernate an instance that has more than 16 GB of RAM.
- If you create a snapshot or AMI from an instance that is hibernated or has hibernation enabled, you might not be able to connect to a new instance that is launched from the AMI or from an AMI that was created from the snapshot.
- You can't change the instance type or size of an instance when hibernation is enabled.
- You can't hibernate an instance that is in an Auto Scaling group or used by Amazon ECS. If your instance is in an Auto Scaling group and you try to hibernate it, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and might terminate it and launch a replacement instance. For more information, see [Health Checks for Auto Scaling Instances](#) in the *Amazon EC2 Auto Scaling User Guide*.
- You can't hibernate an instance that is configured to boot in UEFI mode.
- If you hibernate an instance that was launched into a Capacity Reservation, the Capacity Reservation does not ensure that the hibernated instance can resume after you try to start it.
- You can't hibernate an instance that uses a kernel below 5.10 if Federal Information Processing Standard (FIPS) mode is enabled.
- We do not support keeping an instance hibernated for more than 60 days. To keep the instance for longer than 60 days, you must start the hibernated instance, stop the instance, and start it.
- We constantly update our platform with upgrades and security patches, which can conflict with existing hibernated instances. We notify you about critical updates that require a start for hibernated instances so that we can perform a shutdown or a reboot to apply the necessary upgrades and security patches.

Enable hibernation for an instance

To hibernate an instance, you must first enable it for hibernation while launching the instance.

Important

You can't enable or disable hibernation for an instance after you launch it.

New console

To enable hibernation using the console

1. Follow the procedure to [launch an instance \(p. 554\)](#), but don't launch the instance until you've completed the following steps to enable hibernation.
2. To enable hibernation, configure the following fields in the launch instance wizard:
 - a. Under **Application and OS Images (Amazon Machine Image)**, select an AMI that supports hibernation. For more information, see [Supported Windows AMIs \(p. 604\)](#).
 - b. Under **Instance type**, select a supported instance type. For more information, see [Supported instance families \(p. 604\)](#).
 - c. Under **Configure storage**, choose **Advanced** (at the right), and specify the following information for the root volume:
 - For **Size (GiB)**, enter the EBS root volume size. The volume must be large enough to store the RAM contents and accommodate your expected usage.
 - For **Volume type**, select a supported EBS volume type: General Purpose SSD (gp2 and gp3) or Provisioned IOPS SSD (io1 and io2).
 - For **Encrypted**, choose **Yes**. If you enabled encryption by default in this AWS Region, **Yes** is selected.
 - For **KMS key**, select the encryption key for the volume. If you enabled encryption by default in this AWS Region, the default encryption key is selected.

For more information about the prerequisites for the root volume, see [Hibernation prerequisites \(p. 603\)](#).

- d. Expand **Advanced details**, and for **Stop - Hibernate behavior**, choose **Enable**.
3. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**.
For more information, see [Launch an instance using the new launch instance wizard \(p. 552\)](#).

Old console

To enable hibernation using the console

1. Follow the [Launch an instance using the old launch instance wizard \(p. 561\)](#) procedure.
2. On the **Choose an Amazon Machine Image (AMI)** page, select an AMI that supports hibernation. For more information about supported AMIs, see [Hibernation prerequisites \(p. 603\)](#).
3. On the **Choose an Instance Type** page, select a supported instance type, and choose **Next: Configure Instance Details**. For information about supported instance types, see [Hibernation prerequisites \(p. 603\)](#).
4. On the **Configure Instance Details** page, for **Stop - Hibernate Behavior**, select the **Enable hibernation as an additional stop behavior** check box.
5. On the **Add Storage** page, for the root volume, specify the following information:
 - For **Size (GiB)**, enter the EBS root volume size. The volume must be large enough to store the RAM contents and accommodate your expected usage.
 - For **Volume Type**, select a supported EBS volume type, General Purpose SSD (gp2 and gp3) or Provisioned IOPS SSD (io1 and io2).
 - For **Encryption**, select the encryption key for the volume. If you enabled encryption by default in this AWS Region, the default encryption key is selected.

For more information about the prerequisites for the root volume, see [Hibernation prerequisites \(p. 603\)](#).

6. Continue as prompted by the wizard. When you've finished reviewing your options on the **Review Instance Launch** page, choose **Launch**. For more information, see [Launch an instance using the old launch instance wizard \(p. 561\)](#).

AWS CLI

To enable hibernation using the AWS CLI

Use the [run-instances](#) command to launch an instance. Specify the EBS root volume parameters using the `--block-device-mappings file://mapping.json` parameter, and enable hibernation using the `--hibernation-options Configured=true` parameter.

```
aws ec2 run-instances \
--image-id ami-0abcdef1234567890 \
--instance-type m5.large \
--block-device-mappings file://mapping.json \
--hibernation-options Configured=true \
--count 1 \
--key-name MyKeyPair
```

Specify the following in `mapping.json`.

```
[
```

```
{  
    "DeviceName": "/dev/xvda",  
    "Ebs": {  
        "VolumeSize": 30,  
        "VolumeType": "gp2",  
        "Encrypted": true  
    }  
}
```

Note

The value for DeviceName must match the root device name that's associated with the AMI. To find the root device name, use the [describe-images](#) command.

```
aws ec2 describe-images --image-id ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit "Encrypted": true.

PowerShell

To enable hibernation using the AWS Tools for Windows PowerShell

Use the [New-EC2Instance](#) command to launch an instance. Specify the EBS root volume by first defining the block device mapping, and then adding it to the command using the -BlockDeviceMappings parameter. Enable hibernation using the -HibernationOptions_Configured \$true parameter.

```
PS C:\> $ebs_encrypt = New-Object Amazon.EC2.Model.BlockDeviceMapping  
PS C:\> $ebs_encrypt.DeviceName = "/dev/xvda"  
PS C:\> $ebs_encrypt.Ebs = New-Object Amazon.EC2.Model.EbsBlockDevice  
PS C:\> $ebs_encrypt.Ebs.VolumeSize = 30  
PS C:\> $ebs_encrypt.Ebs.VolumeType = "gp2"  
PS C:\> $ebs_encrypt.Ebs.Encrypted = $true  
  
PS C:\> New-EC2Instance `  
      -ImageId ami-0abcdef1234567890 `  
      -InstanceType m5.large `  
      -BlockDeviceMappings $ebs_encrypt `  
      -HibernationOptions_Configured $true `  
      -MinCount 1 `  
      -MaxCount 1 `  
      -KeyName MyKeyPair
```

Note

The value for DeviceName must match the root device name associated with the AMI. To find the root device name, use the [Get-EC2Image](#) command.

```
Get-EC2Image -ImageId ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit Encrypted = \$true from the block device mapping.

Console

To view if an instance is enabled for hibernation

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Instances**.
3. Select the instance and, on the **Details** tab, in the **Instance details** section, inspect **Stop-hibernate behavior**. **Enabled** indicates that the instance is enabled for hibernation.

AWS CLI

To view if an instance is enabled for hibernation

Use the [describe-instances](#) command and specify the `--filters "Name=hibernation-options.configured,Values=true"` parameter to filter instances that are enabled for hibernation.

```
aws ec2 describe-instances \
    --filters "Name=hibernation-options.configured,Values=true"
```

The following field in the output indicates that the instance is enabled for hibernation.

```
"HibernationOptions": {
    "Configured": true
}
```

PowerShell

To view if an instance is enabled for hibernation using the AWS Tools for Windows PowerShell

Use the [Get-EC2Instance](#) command and specify the `-Filter @{ Name="hibernation-options.configured"; Value="true"}` parameter to filter instances that are enabled for hibernation.

```
Get-EC2Instance ` 
    -Filter @{ Name="hibernation-options.configured"; Value="true"}
```

The output lists the EC2 instances that are enabled for hibernation.

Hibernate an instance

You can hibernate an instance if the instance is [enabled for hibernation \(p. 606\)](#) and meets the [hibernation prerequisites \(p. 603\)](#). If an instance cannot hibernate successfully, a normal shutdown occurs.

Console

To hibernate an Amazon EBS-backed instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and choose **Instance state, Hibernate instance**. If **Hibernate instance** is disabled, the instance is already hibernated or stopped, or it can't be hibernated. For more information, see [Hibernate prerequisites \(p. 603\)](#).
4. When prompted for confirmation, choose **Hibernate**. It can take a few minutes for the instance to hibernate. The instance state first changes to **Stopping**, and then changes to **Stopped** when the instance has hibernated.

AWS CLI

To hibernate an Amazon EBS-backed instance

Use the [stop-instances](#) command and specify the --hibernate parameter.

```
aws ec2 stop-instances \
--instance-ids i-1234567890abcdef0 \
--hibernate
```

PowerShell

To hibernate an Amazon EBS-backed instance using the AWS Tools for Windows PowerShell

Use the [Stop-EC2Instance](#) command and specify the -Hibernate \$true parameter.

```
Stop-EC2Instance ` 
-InstanceId i-1234567890abcdef0 ` 
-Hibernate $true
```

Console

To view if hibernation was initiated on an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and, on the **Details** tab, in the **Instance details** section, inspect **State transition message**. The message **Client.UserInitiatedHibernate: User initiated hibernate** indicates that hibernation was initiated on the instance.

AWS CLI

To view if hibernation was initiated on an instance

Use the [describe-instances](#) command and specify the state-reason-code filter to see the instances on which hibernation was initiated.

```
aws ec2 describe-instances \
--filters "Name=state-reason-code,Values=Client.UserInitiatedHibernate"
```

The following field in the output indicates that hibernation was initiated on the instance.

```
"StateReason": { 
    "Code": "Client.UserInitiatedHibernate"
}
```

PowerShell

To view if hibernation was initiated on an instance using the AWS Tools for Windows PowerShell

Use the [Get-EC2Instance](#) command and specify the state-reason-code filter to see the instances on which hibernation was initiated.

```
Get-EC2Instance `
```

```
-Filter @{Name="state-reason-code";Value="Client.UserInitiatedHibernate"}
```

The output lists the EC2 instances on which hibernation was initiated.

Start a hibernated instance

Start a hibernated instance by starting it in the same way that you would start a stopped instance.

Console

To start a hibernated instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select a hibernated instance, and choose **Instance state, Start instance**. It can take a few minutes for the instance to enter the `running` state. During this time, the instance [status checks \(p. 1154\)](#) show the instance in a failed state until the instance has started.

AWS CLI

To start a hibernated instance

Use the [start-instances](#) command.

```
aws ec2 start-instances \
--instance-ids i-1234567890abcdef0
```

PowerShell

To start a hibernated instance using the AWS Tools for Windows PowerShell

Use the [Start-EC2Instance](#) command.

```
Start-EC2Instance ` 
-InstanceId i-1234567890abcdef0
```

Troubleshoot hibernation

Use this information to help diagnose and fix issues that you might encounter when hibernating an instance.

Can't hibernate immediately after launch

If you try to hibernate an instance too quickly after you've launched it, you get an error.

You must wait for about five minutes after launch before hibernating.

Takes too long to transition from stopping to stopped, and memory state not restored after start

If it takes a long time for your hibernating instance to transition from the stopping state to stopped, and if the memory state is not restored after you start, this could indicate that hibernation was not properly configured.

Windows Server 2016 and later

Check the EC2 launch log and look for messages that are related to hibernation. To access the EC2 launch log, [connect \(p. 626\)](#) to the instance and open the C:\ProgramData\Amazon\EC2-Windows\Launch\Log\Ec2Launch.log file in a text editor.

Note

By default, Windows hides files and folders under C:\ProgramData. To view EC2 Launch directories and files, enter the path in Windows Explorer or change the folder properties to show hidden files and folders.

Find the log lines for hibernation. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.

For example, the following message indicates that hibernation failed to configure: Message: Failed to enable hibernation.

If the log line contains HibernationEnabled: true, hibernation was successfully configured.

Windows Server 2012 R2 and earlier

Check the EC2 config log and look for messages that are related to hibernation. To access the EC2 config log, [connect \(p. 626\)](#) to the instance and open the C:\Program Files\Amazon\Ec2ConfigService\Logs\Ec2ConfigLog.txt file in a text editor. Find the log lines for SetHibernateOnSleep. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.

For example, the following message indicates that the instance root volume is not large enough: SetHibernateOnSleep: Failed to enable hibernation: Hibernation failed with the following error: There is not enough space on the disk.

If the log line is SetHibernateOnSleep: HibernationEnabled: true, hibernation was successfully configured.

If you do not see any logs from these processes, your AMI might not support hibernation. For information about supported AMIs, see [Hibernation prerequisites \(p. 603\)](#).

Instance size

If you're using a T3 or T3a instance with less than 1 GB of RAM, try increasing the size of the instance to one that has at least 1 GB of RAM.

Instance "stuck" in the stopping state

If you hibernated your instance and it appears "stuck" in the stopping state, you can forcibly stop it. For more information, see [Troubleshoot stopping your instance \(p. 2145\)](#).

Reboot your instance

An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance.

When you reboot an instance, it keeps the following:

- Public DNS name (IPv4)
- Private IPv4 address
- Public IPv4 address
- IPv6 address (if applicable)
- Any data on its instance store volumes

Rebooting an instance doesn't start a new instance billing period (with a minimum one-minute charge), unlike [stopping and starting \(p. 594\)](#) your instance.

We might schedule your instance for a reboot for necessary maintenance, such as to apply updates that require a reboot. No action is required on your part; we recommend that you wait for the reboot to occur within its scheduled window. For more information, see [Scheduled events for your instances \(p. 1160\)](#).

We recommend that you use the Amazon EC2 console, a command line tool, or the Amazon EC2 API to reboot your instance instead of running the operating system reboot command from your instance. If you use the Amazon EC2 console, a command line tool, or the Amazon EC2 API to reboot your instance, we perform a hard reboot if the instance does not cleanly shut down within a few minutes. If you use AWS CloudTrail, then using Amazon EC2 to reboot your instance also creates an API record of when your instance was rebooted.

If Windows is installing updates on your instance, we recommend that you do not reboot or shut down your instance using the Amazon EC2 console or the command line until all the updates are installed. When you use the Amazon EC2 console or the command line to reboot or shut down your instance, there is a risk that your instance will be hard rebooted. A hard reboot while updates are being installed could throw your instance into an unstable state.

Console

To reboot an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Instance state, Reboot instance**.

Alternatively, select the instance and choose **Actions, Manage instance state**. In the screen that opens, choose **Reboot**, and then **Change state**.

4. Choose **Reboot** when prompted for confirmation.

The instance remains in the `running` state.

Command line

To reboot an instance

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [reboot-instances](#) (AWS CLI)
- [Restart-EC2Instance](#) (AWS Tools for Windows PowerShell)

To run a controlled fault injection experiment

You can use AWS Fault Injection Simulator to test how your application responds when your instance is rebooted. For more information, see the [AWS Fault Injection Simulator User Guide](#).

Instance retirement

An instance is scheduled to be retired when AWS detects irreparable failure of the underlying hardware that hosts the instance. When an instance reaches its scheduled retirement date, it is stopped by AWS. If your instance root device is an Amazon EBS volume, the instance is stopped, and you can start it again at any time. Starting the stopped instance migrates it to new hardware.

For more information about the types of instance events, see [Scheduled events for your instances \(p. 1160\)](#).

Contents

- [Identify instances scheduled for retirement \(p. 614\)](#)
- [Actions to take for instances scheduled for retirement \(p. 615\)](#)

Identify instances scheduled for retirement

If your instance is scheduled for retirement, you receive an email prior to the event with the instance ID and retirement date. You can also check for instances that are scheduled for retirement using the Amazon EC2 console or the command line.

Important

If an instance is scheduled for retirement, we recommend that you take action as soon as possible because the instance might be unreachable. (The email notification you receive states the following: "Due to this degradation your instance could already be unreachable.") For more information about the recommended action you should take, see [Check if your instance is reachable](#).

Ways to identify instances scheduled for retirement

- [Email notification \(p. 614\)](#)
- [Console identification \(p. 614\)](#)

Email notification

If your instance is scheduled for retirement, you receive an email prior to the event with the instance ID and retirement date.

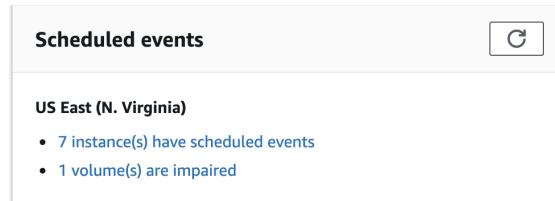

The email is sent to the primary account holder and the operations contact. For more information, see [Adding, changing, or removing alternate contacts](#) in the *AWS Billing User Guide*.

Console identification

If you use an email account that you do not check regularly for instance retirement notifications, you can use the Amazon EC2 console or the command line to determine if any of your instances are scheduled for retirement.

To identify instances scheduled for retirement using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **EC2 Dashboard**. Under **Scheduled events**, you can see the events that are associated with your Amazon EC2 instances and volumes, organized by Region.

3. If you have an instance with a scheduled event listed, select its link below the Region name to go to the **Events** page.
4. The **Events** page lists all resources that have events associated with them. To view instances that are scheduled for retirement, select **Instance resources** from the first filter list, and then **Instance stop or retirement** from the second filter list.

5. If the filter results show that an instance is scheduled for retirement, select it, and note the date and time in the **Start time** field in the details pane. This is your instance retirement date.

To identify instances scheduled for retirement using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [describe-instance-status](#) (AWS CLI)
- [Get-EC2InstanceState](#) (AWS Tools for Windows PowerShell)

Actions to take for instances scheduled for retirement

To preserve the data on your retiring instance, you can perform one of the following actions. It's important that you take this action before the instance retirement date to prevent unforeseen downtime and data loss.

Check if your instance is reachable

When you are notified that your instance is scheduled for retirement, we recommend that you take the following action as soon as possible:

- Check if your instance is reachable by either [connecting \(p. 626\)](#) to or pinging your instance.
- If your instance is reachable, you should plan to stop/start your instance at an appropriate time before the scheduled retirement date, when the impact is minimal. For more information about stopping and starting your instance, and what to expect when your instance is stopped, such as the effect on public, private, and Elastic IP addresses that are associated with your instance, see [Stop and start your instance \(p. 594\)](#). Note that data on instance store volumes is lost when you stop and start your instance.
- If your instance is unreachable, you should take immediate action and perform a [stop/start \(p. 594\)](#) to recover your instance.
- Alternatively, if you want to [terminate \(p. 615\)](#) your instance, plan to do so as soon as possible so that you stop incurring charges for the instance.

Create a backup of your instance

Create an EBS-backed AMI from your instance so that you have a backup. To ensure data integrity, stop the instance before you create the AMI. You can wait for the scheduled retirement date when the instance is stopped, or stop the instance yourself before the retirement date. You can start the instance again at any time. For more information, see [Create a custom Windows AMI \(p. 151\)](#).

Launch a replacement instance

After you create an AMI from your instance, you can use the AMI to launch a replacement instance. From the Amazon EC2 console, select your new AMI and then choose **Actions, Launch**. Follow the wizard to launch your instance. For more information about each step in the wizard, see [Launch an instance using the new launch instance wizard \(p. 552\)](#).

Terminate your instance

You can delete your instance when you no longer need it. This is referred to as *terminating* your instance. As soon as the state of an instance changes to **shutting-down** or **terminated**, you stop incurring charges for that instance.

You can't connect to or start an instance after you've terminated it. However, you can launch additional instances using the same AMI. If you'd rather stop and start your instance, or hibernate it, see [Stop and](#)

[start your instance \(p. 594\)](#) or [Hibernate your On-Demand Windows instance \(p. 602\)](#). For more information, see [Differences between reboot, stop, hibernate, and terminate \(p. 549\)](#).

Contents

- [Instance termination \(p. 616\)](#)
- [Terminating multiple instances with termination protection across Availability Zones \(p. 616\)](#)
- [What happens when you terminate an instance \(p. 617\)](#)
- [Terminate an instance \(p. 617\)](#)
- [Enable termination protection \(p. 618\)](#)
- [Change the instance initiated shutdown behavior \(p. 619\)](#)
- [Preserve Amazon EBS volumes on instance termination \(p. 620\)](#)

Instance termination

After you terminate an instance, it remains visible in the console for a short while, and then the entry is automatically deleted. You cannot delete the terminated instance entry yourself. After an instance is terminated, resources such as tags and volumes are gradually disassociated from the instance and may no longer be visible on the terminated instance after a short while.

When an instance terminates, the data on any instance store volumes associated with that instance is deleted.

By default, Amazon EBS root device volumes are automatically deleted when the instance terminates. However, by default, any additional EBS volumes that you attach at launch, or any EBS volumes that you attach to an existing instance persist even after the instance terminates. This behavior is controlled by the volume's `DeleteOnTermination` attribute, which you can modify. For more information, see [Preserve Amazon EBS volumes on instance termination \(p. 620\)](#).

You can prevent an instance from being terminated accidentally by someone using the AWS Management Console, the CLI, and the API. This feature is available for both Amazon EC2 instance store-backed and Amazon EBS-backed instances. Each instance has a `DisableApiTermination` attribute with the default value of `false` (the instance can be terminated through Amazon EC2). You can modify this instance attribute while the instance is running or stopped (in the case of Amazon EBS-backed instances). For more information, see [Enable termination protection \(p. 618\)](#).

You can control whether an instance should stop or terminate when shutdown is initiated from the instance using an operating system command for system shutdown. For more information, see [Change the instance initiated shutdown behavior \(p. 619\)](#).

If you run a script on instance termination, your instance might have an abnormal termination, because we have no way to ensure that shutdown scripts run. Amazon EC2 attempts to shut an instance down cleanly and run any system shutdown scripts; however, certain events (such as hardware failure) may prevent these system shutdown scripts from running.

Terminating multiple instances with termination protection across Availability Zones

If you terminate multiple instances across multiple Availability Zones, and one or more of the specified instances are enabled for termination protection, the request fails with the following results:

- The specified instances that are in the same Availability Zone as the protected instance are not terminated.
- The specified instances that are in different Availability Zones, where no other specified instances are protected, are successfully terminated.

For example, say you have the following instances:

Instance	Availability Zone	Terminate protection
Instance A	us-east-1a	Disabled
Instance B		Disabled
Instance C	us-east-1b	Enabled
Instance D		Disabled

If you attempt to terminate all of these instances in the same request, the request reports failure with the following results:

- **Instance A** and **Instance B** are successfully terminated because none of the specified instances in us-east-1a are enabled for termination protection.
- **Instance C** and **Instance D** fail to terminate because at least one of the specified instances in us-east-1b (**Instance C**) is enabled for termination protection.

What happens when you terminate an instance

When an EC2 instance is terminated using the `terminate-instances` command, the following is registered at the OS level:

- The API request will send a button press event to the guest.
- Various system services will be stopped as a result of the button press event. `systemd` handles a graceful shutdown of the system. Graceful shutdown is triggered by the ACPI shutdown button press event from the hypervisor.
- ACPI shutdown will be initiated.
- The instance will shut down when the graceful shutdown process exits. There is no configurable OS shutdown time.

Terminate an instance

You can terminate an instance using the AWS Management Console or the command line.

By default, when you initiate a shutdown from an Amazon EBS-backed instance (using the `shutdown` or `poweroff` commands), the instance stops. The `halt` command does not initiate a shutdown. If used, the instance does not terminate; instead, it places the CPU into HLT and the instance remains running.

Console

To terminate an instance

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
3. In the navigation pane, choose **Instances**.
4. Select the instance, and choose **Instance state, Terminate instance**.
5. Choose **Terminate** when prompted for confirmation.

Command line

To terminate an instance

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [terminate-instances](#) (AWS CLI)
- [Remove-EC2Instance](#) (AWS Tools for Windows PowerShell)

To run a controlled fault injection experiment

You can use AWS Fault Injection Simulator to test how your application responds when your instance is terminated. For more information, see the [AWS Fault Injection Simulator User Guide](#).

Enable termination protection

By default, you can terminate your instance using the Amazon EC2 console, command line interface, or API. To prevent your instance from being accidentally terminated using Amazon EC2, you can enable *termination protection* for the instance. The `DisableApiTermination` attribute controls whether the instance can be terminated using the console, CLI, or API. By default, termination protection is disabled for your instance. You can set the value of this attribute when you launch the instance, while the instance is running, or while the instance is stopped (for Amazon EBS-backed instances).

The `DisableApiTermination` attribute does not prevent you from terminating an instance by initiating shutdown from the instance (using an operating system command for system shutdown) when the `InstanceInitiatedShutdownBehavior` attribute is set. For more information, see [Change the instance initiated shutdown behavior \(p. 619\)](#).

Limitations

You can't enable termination protection for Spot Instances—a Spot Instance is terminated when the Spot price exceeds the amount you're willing to pay for Spot Instances. However, you can prepare your application to handle Spot Instance interruptions. For more information, see [Spot Instance interruptions \(p. 433\)](#).

The `DisableApiTermination` attribute does not prevent Amazon EC2 Auto Scaling from terminating an instance. For instances in an Auto Scaling group, use the following Amazon EC2 Auto Scaling features instead of Amazon EC2 termination protection:

- To prevent instances that are part of an Auto Scaling group from terminating on scale in, use instance scale-in protection. For more information, see [Using instance scale-in protection](#) in the *Amazon EC2 Auto Scaling User Guide*.
- To prevent Amazon EC2 Auto Scaling from terminating unhealthy instances, suspend the `ReplaceUnhealthy` process. For more information, see [Suspending and Resuming Scaling Processes](#) in the *Amazon EC2 Auto Scaling User Guide*.
- To specify which instances Amazon EC2 Auto Scaling should terminate first, choose a termination policy. For more information, see [Customizing the Termination Policy](#) in the *Amazon EC2 Auto Scaling User Guide*.

To enable termination protection for an instance at launch time

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the dashboard, choose **Launch Instance** and follow the directions in the wizard.
3. On the **Configure Instance Details** page, select the **Enable termination protection** check box.

To enable termination protection for a running or stopped instance

1. Select the instance, and choose **Actions, Instance Settings, Change Termination Protection**.
2. Choose **Yes, Enable**.

To disable termination protection for a running or stopped instance

1. Select the instance, and choose **Actions, Instance Settings, Change Termination Protection**.
2. Choose **Yes, Disable**.

To enable or disable termination protection using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [modify-instance-attribute](#) (AWS CLI)
- [Edit-EC2InstanceAttribute](#) (AWS Tools for Windows PowerShell)

Change the instance initiated shutdown behavior

By default, when you initiate a shutdown from an Amazon EBS-backed instance (using a command such as **shutdown** or **poweroff**), the instance stops (Note that **halt** does not issue a **poweroff** command and, if used, the instance will not terminate; instead, it will place the CPU into HLT and the instance will remain running). You can change this behavior using the **InstanceInitiatedShutdownBehavior** attribute for the instance so that it terminates instead. You can update this attribute while the instance is running or stopped.

You can update the **InstanceInitiatedShutdownBehavior** attribute using the Amazon EC2 console or the command line. The **InstanceInitiatedShutdownBehavior** attribute only applies when you perform a shutdown from the operating system of the instance itself; it does not apply when you stop an instance using the **StopInstances** API or the Amazon EC2 console.

Console

To change the shutdown behavior of an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions, Instance settings, Change shutdown behavior**. The current behavior is selected.
5. To change the behavior, select **Stop** or **Terminate** from **Shutdown behavior** and then choose **Apply**.

Command line

To change the shutdown behavior of an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [modify-instance-attribute](#) (AWS CLI)
- [Edit-EC2InstanceAttribute](#) (AWS Tools for Windows PowerShell)

Preserve Amazon EBS volumes on instance termination

When an instance terminates, Amazon EC2 uses the value of the `DeleteOnTermination` attribute for each attached Amazon EBS volume to determine whether to preserve or delete the volume.

The default value for the `DeleteOnTermination` attribute differs depending on whether the volume is the root volume of the instance or a non-root volume attached to the instance.

Root volume

By default, the `DeleteOnTermination` attribute for the root volume of an instance is set to `true`. Therefore, the default is to delete the root volume of the instance when the instance terminates. The `DeleteOnTermination` attribute can be set by the creator of an AMI as well as by the person who launches an instance. When the attribute is changed by the creator of an AMI or by the person who launches an instance, the new setting overrides the original AMI default setting. We recommend that you verify the default setting for the `DeleteOnTermination` attribute after you launch an instance with an AMI.

Non-root volume

By default, when you [attach a non-root EBS volume to an instance \(p. 1729\)](#), its `DeleteOnTermination` attribute is set to `false`. Therefore, the default is to preserve these volumes. After the instance terminates, you can take a snapshot of the preserved volume or attach it to another instance. You must delete a volume to avoid incurring further charges. For more information, see [Delete an Amazon EBS volume \(p. 1755\)](#).

To verify the value of the `DeleteOnTermination` attribute for an EBS volume that is in use, look at the instance's block device mapping. For more information, see [View the EBS volumes in an instance block device mapping \(p. 2033\)](#).

You can change the value of the `DeleteOnTermination` attribute for a volume when you launch the instance or while the instance is running.

Examples

- [Change the root volume to persist at launch using the console \(p. 620\)](#)
- [Change the root volume to persist at launch using the command line \(p. 621\)](#)
- [Change the root volume of a running instance to persist using the command line \(p. 621\)](#)

Change the root volume to persist at launch using the console

Using the console, you can change the `DeleteOnTermination` attribute when you launch an instance. To change this attribute for a running instance, you must use the command line.

To change the root volume of an instance to persist at launch using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the console dashboard, select **Launch Instance**.
3. On the **Choose an Amazon Machine Image (AMI)** page, choose an AMI and choose **Select**.
4. Follow the wizard to complete the **Choose an Instance Type** and **Configure Instance Details** pages.
5. On the **Add Storage** page, deselect the **Delete On Termination** check box for the root volume.
6. Complete the remaining wizard pages, and then choose **Launch**.

In the new console experience, you can verify the setting by viewing details for the root device volume on the instance's details pane. On the **Storage** tab, under **Block devices**, scroll right to view the **Delete**

on termination setting for the volume. By default, **Delete on termination** is Yes. If you change the default behavior, **Delete on termination** is No.

In the old console experience, you can verify the setting by viewing details for the root device volume on the instance's details pane. Next to **Block devices**, choose the entry for the root device volume. By default, **Delete on termination** is True. If you change the default behavior, **Delete on termination** is False.

Change the root volume to persist at launch using the command line

When you launch an EBS-backed instance, you can use one of the following commands to change the root device volume to persist. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [run-instances](#) (AWS CLI)
- [New-EC2Instance](#) (AWS Tools for Windows PowerShell)

In the block device mappings for the volumes that you want to persist, include --DeleteOnTermination, and specify false.

For example, to persist a volume add the following option to your `run-instances` command:

```
--block-device-mappings file://mapping.json
```

In `mapping.json`, specify the device name, for example `/dev/sda1` or `/dev/xvda`, and for --DeleteOnTermination, specify false.

```
[  
  {  
    "DeviceName": "device_name",  
    "Ebs": {  
      "DeleteOnTermination": false  
    }  
  }  
]
```

Change the root volume of a running instance to persist using the command line

You can use one of the following commands to change the root device volume of a running EBS-backed instance to persist. For more information about these command line interfaces, see [Access Amazon EC2 \(p. 5\)](#).

- [modify-instance-attribute](#) (AWS CLI)
- [Edit-EC2InstanceAttribute](#) (AWS Tools for Windows PowerShell)

For example, use the following command:

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --block-device-mappings file://mapping.json
```

In `mapping.json`, specify the device name, for example `/dev/sda1` or `/dev/xvda`, and for --DeleteOnTermination, specify false.

```
[  
  {  
    "DeviceName": "device_name",  
  }  
]
```

```
    "Ebs": {  
        "DeleteOnTermination": false  
    }  
}
```

Recover your instance

To automatically recover an instance when a system status check failure occurs, you can use the default configuration of the instance or create an Amazon CloudWatch alarm. If an instance becomes unreachable because of an underlying hardware failure or a problem that requires AWS involvement to repair, the instance is automatically recovered.

A recovered instance is identical to the original instance, including the instance ID, private IP addresses, Elastic IP addresses, and all instance metadata. If the impaired instance has a public IPv4 address, the instance retains the public IPv4 address after recovery. If the impaired instance is in a placement group, the recovered instance runs in the placement group. During instance recovery, the instance is migrated as part of an instance reboot, and any data that is in-memory is lost.

Examples of problems that require instance recovery:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

Topics

- [Simplified automatic recovery based on instance configuration \(p. 622\)](#)
- [Amazon CloudWatch action based recovery \(p. 624\)](#)
- [Troubleshoot instance recovery failures \(p. 625\)](#)

Simplified automatic recovery based on instance configuration

Instances that support simplified automatic recovery are configured by default to recover a failed instance. The default configuration applies to new instances that you launch and existing instances that you previously launched. Simplified automatic recovery is initiated in response to system status check failures. Simplified automatic recovery doesn't take place during Service Health Dashboard events, or any other events that impact the underlying hardware. For more information, see [the section called "Troubleshoot instance recovery failures" \(p. 625\)](#).

When a simplified automatic recovery event succeeds, you are notified by an AWS Health Dashboard event. When a simplified automatic recovery event fails, you are notified by an AWS Health Dashboard event and by email. You can also use Amazon EventBridge rules to monitor for simplified automatic recovery events using the following event codes:

- AWS_EC2_SIMPLIFIED_AUTO_RECOVERY_SUCCESS — successful events
- AWS_EC2_SIMPLIFIED_AUTO_RECOVERY_FAILURE — failed events

For more information, see [Amazon EventBridge rules](#).

Topics

- [Requirements \(p. 623\)](#)
- [Limitations \(p. 623\)](#)

- [Set the recovery behavior \(p. 623\)](#)

Requirements

Simplified automatic recovery is supported by an instance if the instance has the following characteristics:

- It uses default or dedicated instance tenancy.
- It does not use an Elastic Fabric Adapter.
- It uses one of the following instance types:
 - **General purpose:** M3 | M4 | M5 | M5a | M5n | M5zn | M6a | M6i | M6in | M7a | M7i | M7i-flex | T1 | T2 | T3 | T3a
 - **Compute optimized:** C3 | C4 | C5 | C5a | C5n | C6a | C6i | C6in | Hpc7a
 - **Memory optimized:** R3 | R4 | R5 | R5a | R5b | R5n | R6a | R6g | R6in | u-3tb1 | u-6tb1 | u-9tb1 | u-12tb1 | u-18tb1 | u-24tb1 | X1 | X1e | X2iezn
 - **Accelerated computing:** G3 | G3s | P2 | P3
- It does not have instance store volumes. If a Nitro instance type has instance store volumes or if a Xen-based instance has mapped instance store volumes, the instance will not be automatically recovered. You should regularly backup your instance store volume data to more persistent storage, such as Amazon EBS, Amazon S3, or Amazon EFS. In the event of a system status check failure, you can stop and start instances with instance store volumes and then restore your instance store volume using the backed-up data.

Limitations

- Instances with instance store volumes and metal instance types are not supported by simplified automatic recovery.
- Simplified automatic recovery is not initiated for instances in an Auto Scaling group. If your instance is part of an Auto Scaling group with health checks enabled, then the instance is replaced when it becomes impaired.
- Simplified automatic recovery applies to unplanned events only. It does not apply to scheduled events.
- Terminated or stopped instances cannot be recovered.

Set the recovery behavior

You can set the automatic recovery behavior to disabled or default during or after launching the instance. The default configuration does not enable simplified automatic recovery for an unsupported instance type.

Console

To disable simplified automatic recovery during instance launch

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**, and then choose **Launch instance**.
3. In the **Advanced details** section, for **Instance auto-recovery**, select **Disabled**.
4. Configure the remaining instance launch settings as needed and then launch the instance.

To disable simplified automatic recovery for a running or stopped instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. In the navigation pane, choose **Instances**.
3. Select the instance, and then choose **Actions**, **Instance settings**, **Change auto-recovery behavior**.
4. Choose **Off**, and then choose **Save**.

To set the automatic recovery behavior to default for a running or stopped instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and then choose **Actions**, **Instance settings**, **Change auto-recovery behavior**.
4. Choose **Default (On)**, and then choose **Save**.

AWS CLI

To disable simplified automatic recovery at launch

Use the [run-instances](#) command.

```
aws ec2 run-instances \
--image-id ami-1a2b3c4d \
--instance-type t2.micro \
--key-name MyKeyPair \
--maintenance-options AutoRecovery=Disabled \
[...]
```

To disable simplified automatic recovery for a running or stopped instance

Use the [modify-instance-maintenance-options](#) command.

```
aws ec2 modify-instance-maintenance-options \
--instance-id i-0abcdef1234567890 \
--auto-recovery disabled
```

To set the automatic recovery behavior to default for a running or stopped instance

Use the [modify-instance-maintenance-options](#) command.

```
aws ec2 modify-instance-maintenance-options \
--instance-id i-0abcdef1234567890 \
--auto-recovery default
```

Amazon CloudWatch action based recovery

Use Amazon CloudWatch action based recovery if you want to customize when to recover your instance.

When the StatusCheckFailed_System alarm is triggered, and the recovery action is initiated, you're notified by the Amazon SNS topic that you selected when you created the alarm and associated the recovery action. When the recovery action is complete, information is published to the Amazon SNS topic you configured for the alarm. Anyone who is subscribed to this Amazon SNS topic receives an email notification that includes the status of the recovery attempt and any further instructions. As a last step in the recovery action, the recovered instance reboots.

You can use Amazon CloudWatch alarms to recover an instance even if simplified automatic recovery is not disabled. For information about creating an Amazon CloudWatch alarm to recover an instance, see [Add recover actions to Amazon CloudWatch alarms \(p. 1210\)](#).

Supported instance types

All of the instance types [supported by simplified automatic recovery \(p. 623\)](#) are also supported by CloudWatch action based recovery. Additionally, Amazon CloudWatch action based recovery supports the following instance types with instance store volumes.

- **General purpose:** M3
- **Compute optimized:** C3
- **Memory optimized:** R3 | X1 | X1e | X2idn | X2iedn

Important

If the instance has instance store volumes attached, the data is lost during recovery.

Amazon CloudWatch action based recovery does not support recovery for instances with Amazon EC2 Dedicated Hosts tenancy and metal instances.

You can use the AWS Management Console or the AWS CLI to view the instance types that support Amazon CloudWatch action based recovery.

Console

To view the instance types that support Amazon CloudWatch action based recovery

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instance Types**.
3. In the filter bar, enter **Auto Recovery support: true**. Alternatively, as you enter the characters and the filter name appears, you can select it.

The **Instance types** table displays all the instance types that support Amazon CloudWatch action based recovery.

AWS CLI

To view the instance types that support Amazon CloudWatch action based recovery

Use the [describe-instance-types](#) command.

```
aws ec2 describe-instance-types --filters Name=auto-recovery-supported,Values=true  
--query "InstanceTypes[*].[InstanceType]" --output text | sort
```

Troubleshoot instance recovery failures

The following issues can cause the recovery of your instance to fail:

- During Service Health Dashboard events, simplified automatic recovery might not recover your instance. You might not receive recovery failure notifications for such events. Any ongoing Service Health Dashboard events might also prevent CloudWatch action based recovery from successfully recovering an instance. For the latest service availability information, see <http://status.aws.amazon.com/>.
- Temporary, insufficient capacity of replacement hardware.

- The instance has reached the maximum daily allowance of three recovery attempts.

The automatic recovery process attempts to recover your instance for up to three separate failures per day. If the instance system status check failure persists, we recommend that you manually stop and start the instance. Data on instance store volumes is lost when the instance is stopped. For more information, see [Stop and start your instance \(p. 594\)](#).

Your instance might subsequently be retired if automatic recovery fails and a hardware degradation is determined to be the root cause for the original system status check failure.

Connect

This section of the *Amazon EC2 User Guide for Windows Instances* provides information to help you connect to your Windows instance after you launch it. It also provides information to help you connect your Windows instance to another AWS resource.

Topics

- [Connect to your Windows instance \(p. 626\)](#)
- [Connect to your instances without requiring a public IPv4 address using EC2 Instance Connect Endpoint \(p. 641\)](#)
- [Connect your EC2 instance to an AWS resource \(p. 664\)](#)

Connect to your Windows instance

You can connect to Amazon EC2 instances created from most Windows Amazon Machine Images (AMIs) using Remote Desktop. Remote Desktop uses the [Remote Desktop Protocol \(RDP\)](#) to connect to and use your instance in the same way you use a computer sitting in front of you (local computer). It is available on most editions of Windows and is also available for Mac OS.

The license for the Windows Server operating system allows two simultaneous remote connections for administrative purposes. The license for Windows Server is included in the price of your Windows instance. If you require more than two simultaneous remote connections, you must purchase a Remote Desktop Services (RDS) license. If you attempt a third connection, an error occurs.

If you need to connect to your instance in order to troubleshoot boot, network configuration, and other issues for instances built on the [AWS Nitro System](#), you can use the [EC2 Serial Console for Windows instances \(p. 2172\)](#).

For information about connecting to a Linux instance, see [Connect to your Linux instance](#) in the *Amazon EC2 User Guide for Linux Instances*.

Tip

You can create an [EC2 Instance Connect Endpoint](#) to connect to your instance using SSH or RDP without a public IPv4 address.

Contents

- [Prerequisites \(p. 627\)](#)
- [Connect to your Windows instance using RDP \(p. 627\)](#)
- [Connect to your Windows instance using Fleet Manager \(p. 633\)](#)
- [Connect to a Windows instance using its IPv6 address \(p. 634\)](#)
- [Connect to a Windows instance using Session Manager \(p. 635\)](#)
- [Configure your accounts \(p. 636\)](#)
- [Transfer files to Windows instances \(p. 637\)](#)

Prerequisites

To connect using RDP

- **Install an RDP client**

- [Windows] Windows includes an RDP client by default. To verify, type **mstsc** at a Command Prompt window. If your computer doesn't recognize this command, see the [Windows home page](#) and search for the download for the Microsoft Remote Desktop app.

- [Mac OS X] Download the [Microsoft Remote Desktop app](#) from the Mac App Store.

- [Linux] Use [Remmina](#).

- **Locate the private key**

Get the fully-qualified path to the location on your computer of the . pem file for the key pair that you specified when you launched the instance. For more information, see [Identify the public key specified at launch](#). If you can't find your private key file, see [I've lost my private key. How can I connect to my Windows instance?](#)

- **Enable inbound RDP traffic from your IP address to your instance**

Ensure that the security group associated with your instance allows incoming RDP traffic (port 3389) from your IP address. The default security group does not allow incoming RDP traffic by default. For more information, see [Authorize inbound traffic for your Windows instances \(p. 1659\)](#).

Note

You do not need to specifically allow incoming RDP traffic from your IP address if you use Fleet Manager to connect. Fleet Manager handles that for you.

- **To connect using Fleet Manager**

For prerequisites, see [Connect using Remote Desktop](#) in the *AWS Systems Manager User Guide*.

Connect to your Windows instance using RDP

To connect to a Windows instance, you must retrieve the initial administrator password and then enter this password when you connect to your instance using Remote Desktop. It takes a few minutes after instance launch before this password is available.

The name of the administrator account depends on the language of the operating system. For example, for English, it's **Administrator**, for French it's **Administrateur**, and for Portuguese it's **Administrador**. For more information, see [Localized Names for Administrator Account in Windows](#) in the Microsoft TechNet Wiki.

If you've joined your instance to a domain, you can connect to your instance using domain credentials you've defined in AWS Directory Service. On the Remote Desktop login screen, instead of using the local computer name and the generated password, use the fully-qualified user name for the administrator (for example, **corp.example.com\Admin**), and the password for this account.

If you receive an error while attempting to connect to your instance, see [Remote Desktop can't connect to the remote computer \(p. 2119\)](#).

New console

To connect to your Windows instance using an RDP client

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, select **Instances**. Select the instance and then choose **Connect**.
3. On the **Connect to instance** page, choose the **RDP client** tab, and then choose **Get password**.

Connect to instance [Info](#)

Connect to your instance i- [REDACTED] (Source-NET-Webserver) using any of these options

Session Manager | **RDP client** | EC2 serial console

Instance ID
i- [REDACTED] (Source-NET-Webserver)

Connection Type

Connect using RDP client
Download a file to use with your RDP client and retrieve your password.

Connect using Fleet Manager
Connect to your instance using Fleet Manager Remote Desktop.

You can connect to your Windows instance using a remote desktop client of your choice, and by downloading and running the RDP shortcut file below:

[Download remote desktop file](#)

When prompted, connect to your instance using the following details:

Public DNS ec2- [REDACTED].us-west-2.compute.amazonaws.com	User name Administrator
-------------------------------------------------------------------------------	--------------------------------------------

[Password](#) [Get password](#)

If you've joined your instance to a directory, you can use your directory credentials to connect to your instance.

[Cancel](#)

4. Choose **Browse** and navigate to the private key (. pem) file you created when you launched the instance. Select the file and choose **Open** to copy the entire contents of the file to this window.
5. Choose **Decrypt Password**. The console displays the default administrator password for the instance under **Password**, replacing the **Get password** link shown previously. Save the password in a safe place. This password is required to connect to the instance.

Connect to instance [Info](#)

Connect to your instance [REDACTED] using any of these options

Session Manager | **RDP client** | EC2 Serial Console

⚠ You may not be able to connect to this instance as ports 3389 may need to be open in order to be accessible. The current associated security groups don't have ports 3389 open. **X**

You can connect to your Windows instance using a remote desktop client of your choice, and by downloading and running the RDP shortcut file below:

[Download remote desktop file](#)

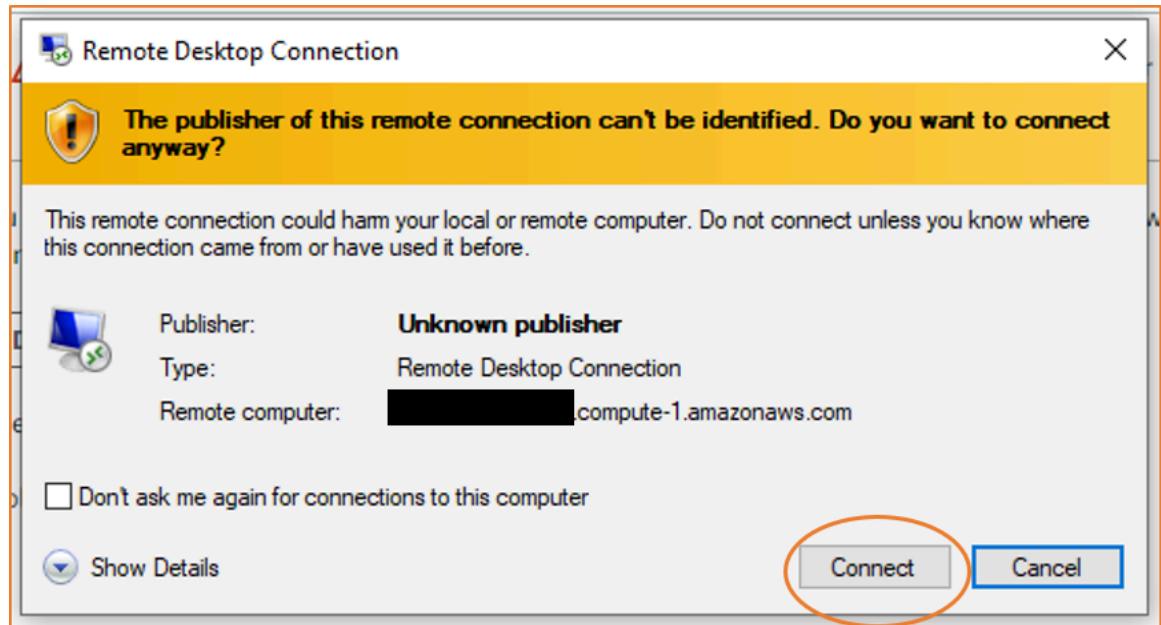

When prompted, connect to your instance using the following details:

Public DNS	User name
<input type="text"/> [REDACTED].compute-1.amazonaws.com	<input type="text"/> Administrator
Password	
<input type="password"/> [REDACTED]	

If you've joined your instance to a directory, you can use your directory credentials to connect to your instance.

Cancel

6. Choose **Download remote desktop file**. Your browser prompts you to either open or save the RDP shortcut file. When you have finished downloading the file, choose **Cancel** to return to the **Instances** page.
 - If you opened the RDP file, you'll see the **Remote Desktop Connection** dialog box.
 - If you saved the RDP file, navigate to your downloads directory, and open the RDP file to display the dialog box.
7. You may get a warning that the publisher of the remote connection is unknown. Choose **Connect** to continue to connect to your instance.

8. The administrator account is chosen by default. Copy and paste the password that you saved previously.

Tip

If you receive a "Password Failed" error, try entering the password manually. Copying and pasting content can corrupt it.

9. Due to the nature of self-signed certificates, you may get a warning that the security certificate could not be authenticated. Use the following steps to verify the identity of the remote computer, or simply choose **Yes** (Windows) or **Continue** (Mac OS X) if you trust the certificate.

- a. If you are using **Remote Desktop Connection** on a Windows computer, choose **View certificate**. If you are using **Microsoft Remote Desktop** on a Mac, choose **Show Certificate**.
- b. Choose the **Details** tab, and scroll down to **Thumbprint** (Windows) or **SHA1 Fingerprints** (Mac OS X). This is the unique identifier for the remote computer's security certificate.
- c. In the Amazon EC2 console, select the instance, choose **Actions, Monitor and troubleshoot, Get system log**.
- d. In the system log output, look for **RDPMESSAGE - THUMBPRINT**. If this value matches the thumbprint or fingerprint of the certificate, you have verified the identity of the remote computer.
- e. If you are using **Remote Desktop Connection** on a Windows computer, return to the **Certificate** dialog box and choose **OK**. If you are using **Microsoft Remote Desktop** on a Mac, return to the **Verify Certificate** and choose **Continue**.
- f. [Windows] Choose **Yes** in the **Remote Desktop Connection** window to connect to your instance.

[Mac OS X] Log in as prompted, using the default administrator account and the default administrator password that you recorded or copied previously. Note that you might need to switch spaces to see the login screen. For more information, see [Add spaces and switch between them](#).

Old console

To connect to your Windows instance using an RDP client

1. In the Amazon EC2 console, select the instance, and then choose **Connect**.
2. In the **Connect To Your Instance** dialog box, choose **Get Password** (it will take a few minutes after the instance is launched before the password is available).
3. Choose **Browse** and navigate to the private key (.pem) file you created when you launched the instance. Select the file and choose **Open** to copy the entire contents of the file into the **Contents** field.
4. Choose **Decrypt Password**. The console displays the default administrator password for the instance in the **Connect To Your Instance** dialog box, replacing the link to **Get Password** shown previously with the actual password.
5. Record the default administrator password, or copy it to the clipboard. You need this password to connect to the instance.
6. Choose **Download Remote Desktop File**. Your browser prompts you to either open or save the .rdp file. Either option is fine. When you have finished, you can choose **Close** to dismiss the **Connect To Your Instance** dialog box.
 - If you opened the .rdp file, you'll see the **Remote Desktop Connection** dialog box.
 - If you saved the .rdp file, navigate to your downloads directory, and open the .rdp file to display the dialog box.
7. You may get a warning that the publisher of the remote connection is unknown. You can continue to connect to your instance.
8. When prompted, log in to the instance, using the administrator account for the operating system and the password that you recorded or copied previously. If your **Remote Desktop Connection** already has an administrator account set up, you might have to choose the **Use another account** option and type the user name and password manually.

Note

Sometimes copying and pasting content can corrupt data. If you encounter a "Password Failed" error when you log in, try typing in the password manually.

9. Due to the nature of self-signed certificates, you may get a warning that the security certificate could not be authenticated. Use the following steps to verify the identity of the remote computer, or simply choose **Yes** or **Continue** to continue if you trust the certificate.
 - a. If you are using **Remote Desktop Connection** from a Windows PC, choose **View certificate**. If you are using **Microsoft Remote Desktop** on a Mac, choose **Show Certificate**.
 - b. Choose the **Details** tab, and scroll down to the **Thumbprint** entry on a Windows PC, or the **SHA1 Fingerprints** entry on a Mac. This is the unique identifier for the remote computer's security certificate.
 - c. In the Amazon EC2 console, select the instance, choose **Actions**, and then choose **Get System Log**.
 - d. In the system log output, look for an entry labeled RDPCERTIFICATE-THUMBPRINT. If this value matches the thumbprint or fingerprint of the certificate, you have verified the identity of the remote computer.
 - e. If you are using **Remote Desktop Connection** from a Windows PC, return to the **Certificate** dialog box and choose **OK**. If you are using **Microsoft Remote Desktop** on a Mac, return to the **Verify Certificate** and choose **Continue**.
 - f. [Windows] Choose **Yes** in the **Remote Desktop Connection** window to connect to your instance.

[Mac OS] Log in as prompted, using the default administrator account and the default administrator password that you recorded or copied previously. Note that you might

need to switch spaces to see the login screen. For more information about spaces, see support.apple.com/en-us/HT204100.

- g. If you receive an error while attempting to connect to your instance, see [Remote Desktop can't connect to the remote computer \(p. 2119\)](#).

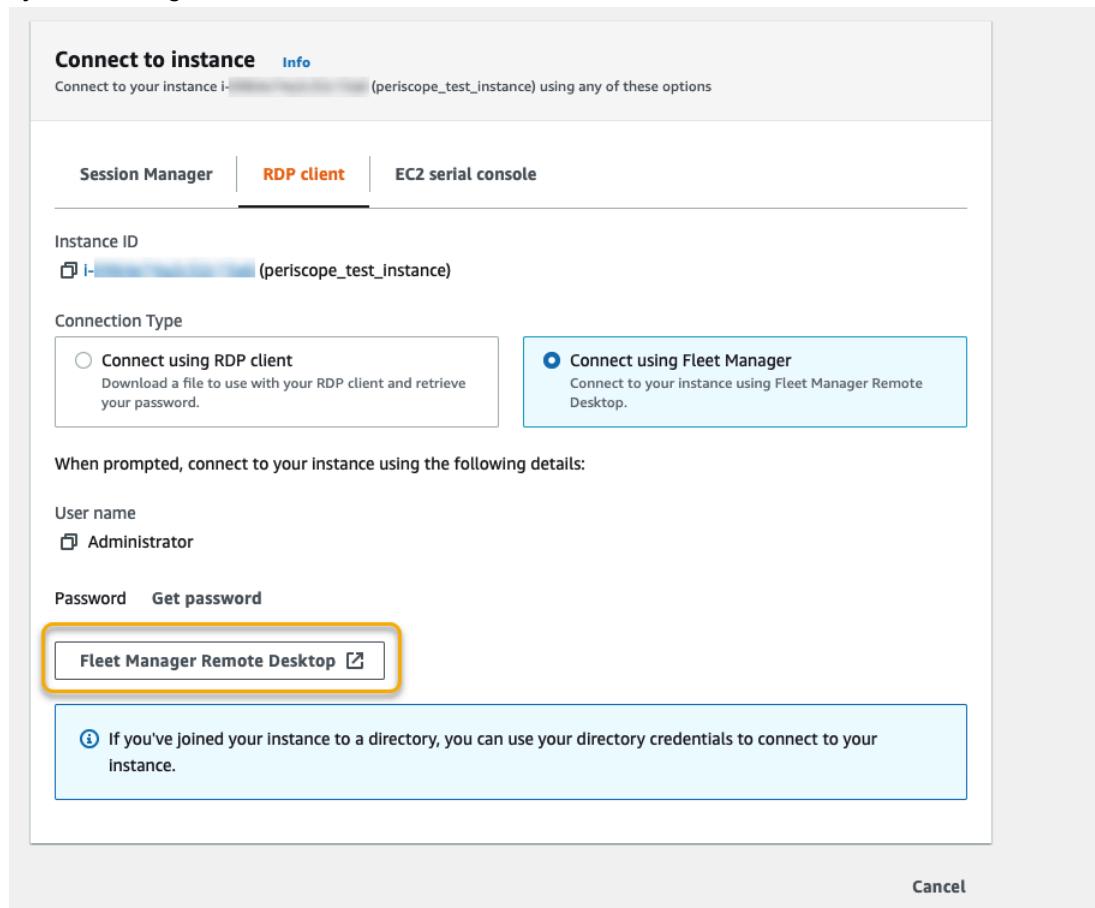

Connect to your Windows instance using Fleet Manager

You can use Fleet Manager, a capability of AWS Systems Manager, to connect to Windows instances using the Remote Desktop Protocol (RDP) and display up to four Windows instances on the same page in the AWS Management Console. You can connect to the first instance in the Fleet Manager Remote Desktop directly from the **Instances** page in the Amazon EC2 console. For more information about Fleet Manager, see [Connect to a managed node using Remote Desktop](#) in the *AWS Systems Manager User Guide*.

Before attempting to connect to an instance using Fleet Manager, ensure that the necessary setup steps have been completed. For more information, see [Setting up Fleet Manager](#).

To connect to instances using RDP with Fleet Manager (console)

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the navigation pane, choose **Instances**.
3. Select the instance and then choose **Connect**.
4. On the **Connect to instance** page, choose the option to **Connect using Fleet Manager**, then choose **Fleet Manager Remote Desktop**. This opens the **Fleet Manager Remote Desktop** page in the AWS Systems Manager console.

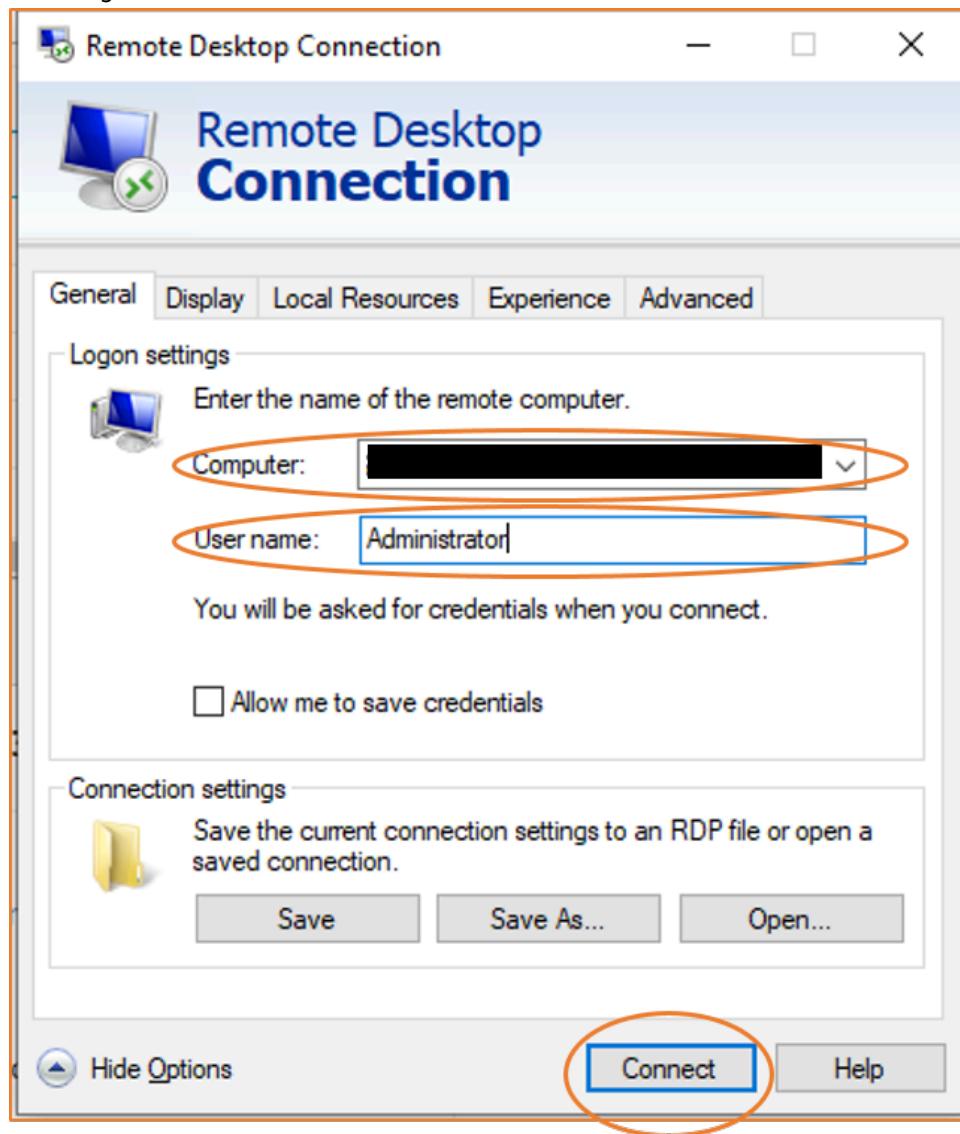

For more information about connecting to Windows instances from the **Fleet Manager Remote Desktop** page, see [Connect using Remote Desktop](#) in the *AWS Systems Manager User Guide*.

Connect to a Windows instance using its IPv6 address

If you've [enabled your VPC for IPv6](#) and [assigned an IPv6 address to your Windows instance \(p. 1241\)](#), you can use an RDP client to connect to your instance using its IPv6 address (for example, 2001:db8:1234:1a00:9691:9503:25ad:1761) instead of using its public IPv4 address or public DNS hostname.

To connect to your Windows instance using its IPv6 address

1. Get the initial administrator password for your instance, as described in [Connect to your Windows instance using RDP \(p. 627\)](#). This password is required to connect to your instance.
2. [Windows] Open the RDP client on your Windows computer, choose **Show Options**, and do the following:

- For **Computer**, enter the IPv6 address of your Windows instance.

- For **User name**, enter **Administrator**.
- Choose **Connect**.
- When prompted, enter the password that you saved previously.

[Mac OS X] Open the RDP client on your computer and do the following:

- Choose **New**.
 - For **PC Name**, enter the IPv6 address of your Windows instance.
 - For **User name**, enter **Administrator**.
 - Close the dialog box. Under **My Desktops**, select the connection, and choose **Start**.
 - When prompted, enter the password that you saved previously.
3. Due to the nature of self-signed certificates, you may get a warning that the security certificate could not be authenticated. If you trust the certificate, you can choose **Yes** or **Continue**. Otherwise, you can verify the identity of the remote computer, as described in [Connect to your Windows instance using RDP \(p. 627\)](#).

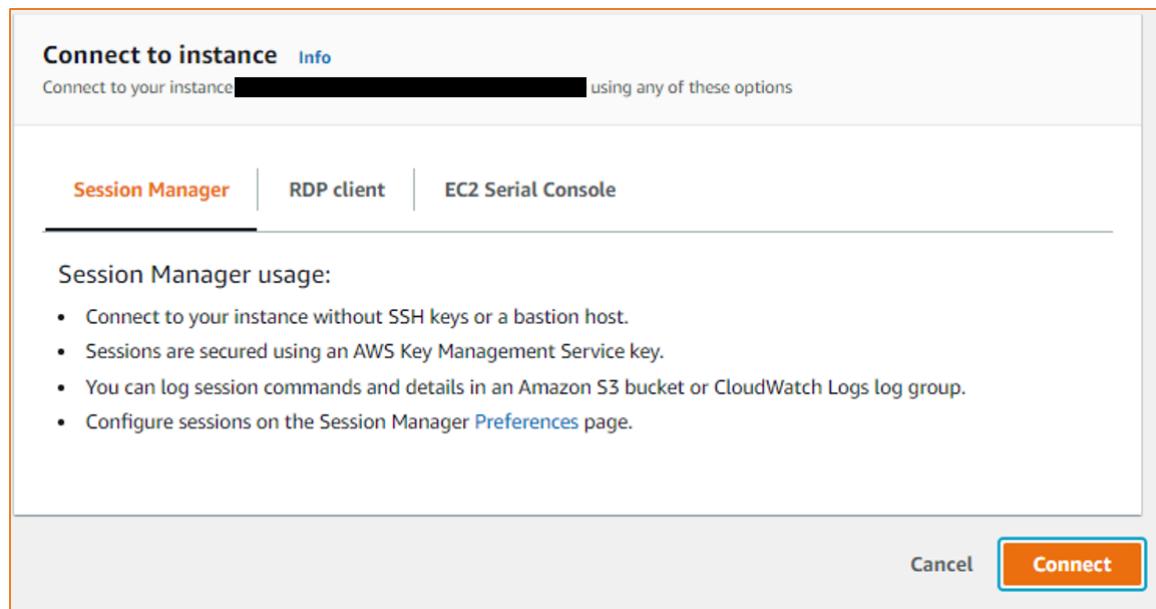

Connect to a Windows instance using Session Manager

Session Manager is a fully-managed AWS Systems Manager capability for managing your Amazon EC2 instances through an interactive, one-click, browser-based shell, or through the AWS CLI. You can use Session Manager to start a session with an instance in your account. After the session is started, you can run PowerShell commands as you would for any other connection type. For more information about Session Manager, see [AWS Systems Manager Session Manager](#) in the *AWS Systems Manager User Guide*.

Before attempting to connect to an instance using Session Manager, ensure that the necessary setup steps have been completed. For more information, see [Setting up Session Manager](#).

To connect to a Windows instance using Session Manager on the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Connect**.
4. For **Connection method**, choose **Session Manager**.
5. Choose **Connect**.

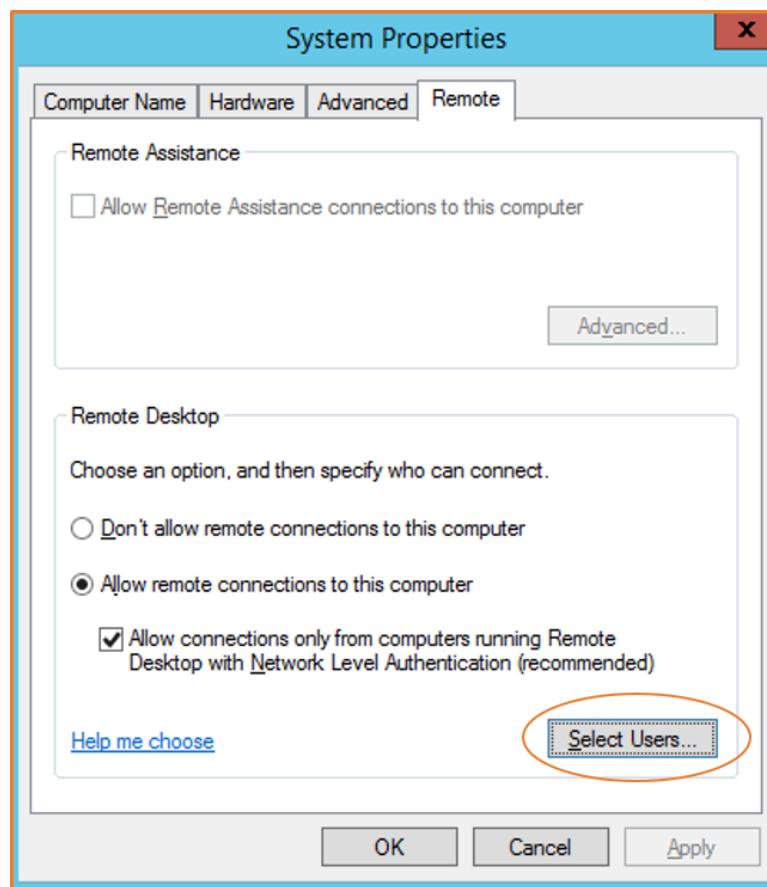

Tip

If you receive an error that you're not authorized to perform one or more Systems Manager actions (`ssm:command-name`), then you must update your policies to allow you to start sessions from the Amazon EC2 console. For more information and instructions, see [Quickstart default IAM policies for Session Manager](#) in the *AWS Systems Manager User Guide*.

Configure your accounts

After you connect, we recommend that you perform the following:

- Change the administrator password from the default value. You [can change the password while you are logged on to the instance itself](#), just as you would on any computer running Windows Server.
- Create another user with administrator privileges on the instance. This is a safeguard in case you forget the administrator password or have a problem with the administrator account. The new user must have permission to access the instance remotely. Open **System Properties** by right-clicking on the **This PC** icon on your Windows desktop or File Explorer and selecting **Properties**. Choose **Remote settings**, and choose **Select Users** to add the user to the **Remote Desktop Users** group.

Transfer files to Windows instances

You can work with your Windows instance in the same way that you would work with any Windows server. For example, you can transfer files between a Windows instance and your local computer using the local file sharing feature of the Microsoft Remote Desktop Connection software. You can access local files on hard disk drives, DVD drives, portable media drives, and mapped network drives.

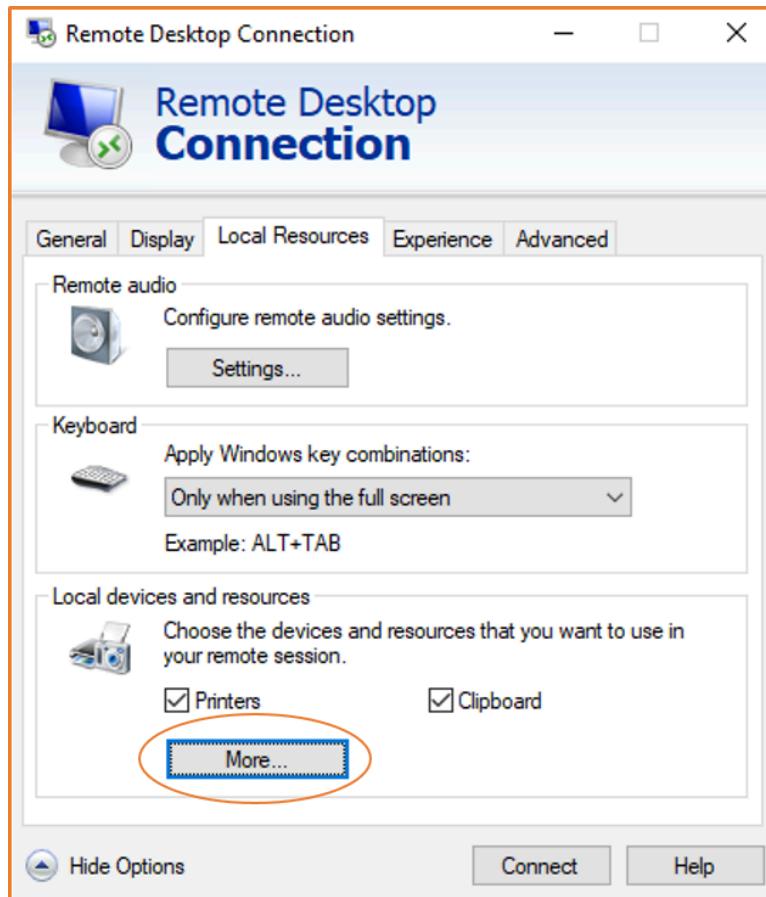

To access your local files from your Windows instances, you must enable the local file sharing feature by mapping the remote session drive to your local drive. The steps are slightly different depending on whether your local computer operating system is Windows or macOS X.

Windows

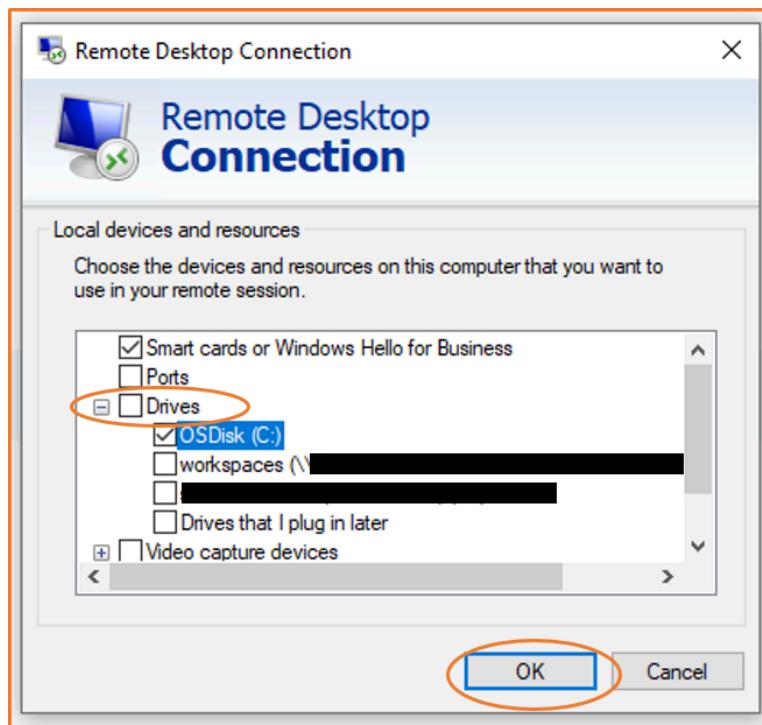

To map the remote session drive to your local drive on your local Windows computer

1. Open the Remote Desktop Connection client.
2. Choose **Show Options**.
3. Add the instance host name to the **Computer** field and user name to the **User name** field, as follows:
 - a. Under **Connection settings**, choose **Open...**, and browse to the RDP shortcut file that you downloaded from the Amazon EC2 console. The file contains the Public IPv4 DNS host name, which identifies the instance, and the Administrator user name.
 - b. Select the file and choose **Open**. The **Computer** and **User name** fields are populated with the values from the RDP shortcut file.

- c. Choose **Save**.
4. Choose the **Local Resources** tab.
5. Under **Local devices and resources**, choose **More...**

6. Open **Drives** and select the local drive to map to your Windows instance.
7. Choose **OK**.

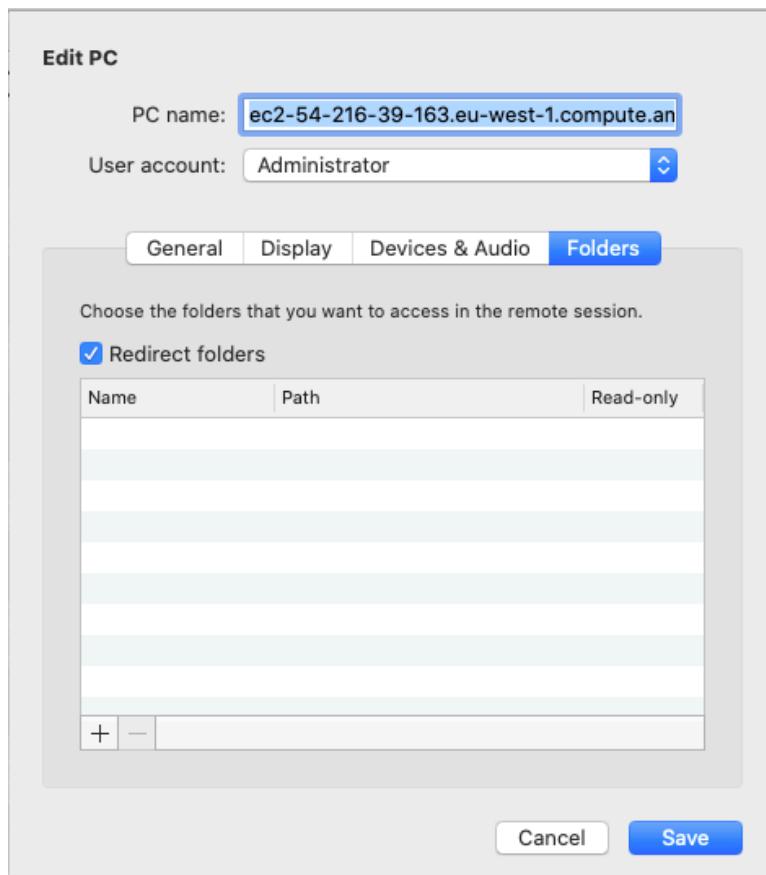

8. Choose **Connect** to connect to your Windows instance.

macOS X

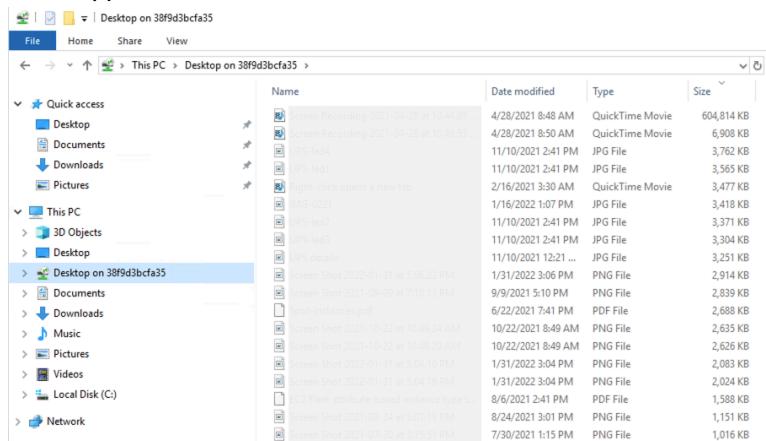

To map the remote session drive to your local folder on your local macOS X computer

1. Open the Remote Desktop Connection client.
2. Browse to the RDP file that you downloaded from the Amazon EC2 console (when you initially connected to the instance), and drag it onto the Remote Desktop Connection client.
3. Right-click the RDP file, and choose **Edit**.
4. Choose the **Folders** tab, and select the **Redirect folders** check box.

Amazon Elastic Compute Cloud
User Guide for Windows Instances
Connect to your instance

5. Choose the + icon at bottom left, browse to the folder to map, and choose **Open**. Repeat this step for every folder to map.
6. Choose **Save**.
7. Choose **Connect** to connect to your Windows instance. You'll be prompted for the password.
8. On the instance, in File Explorer, expand **This PC**, and find the shared folder from which you can access your local files. In the following screenshot, the **Desktop** folder on the local computer was mapped to the remote session drive on the instance.

For more information on making local devices available to a remote session on a Mac computer, see [Get started with the macOS client](#).

Connect to your instances without requiring a public IPv4 address using EC2 Instance Connect Endpoint

EC2 Instance Connect Endpoint allows you to connect to an instance via SSH or RDP without requiring the instance to have a public IPv4 address.

How it works

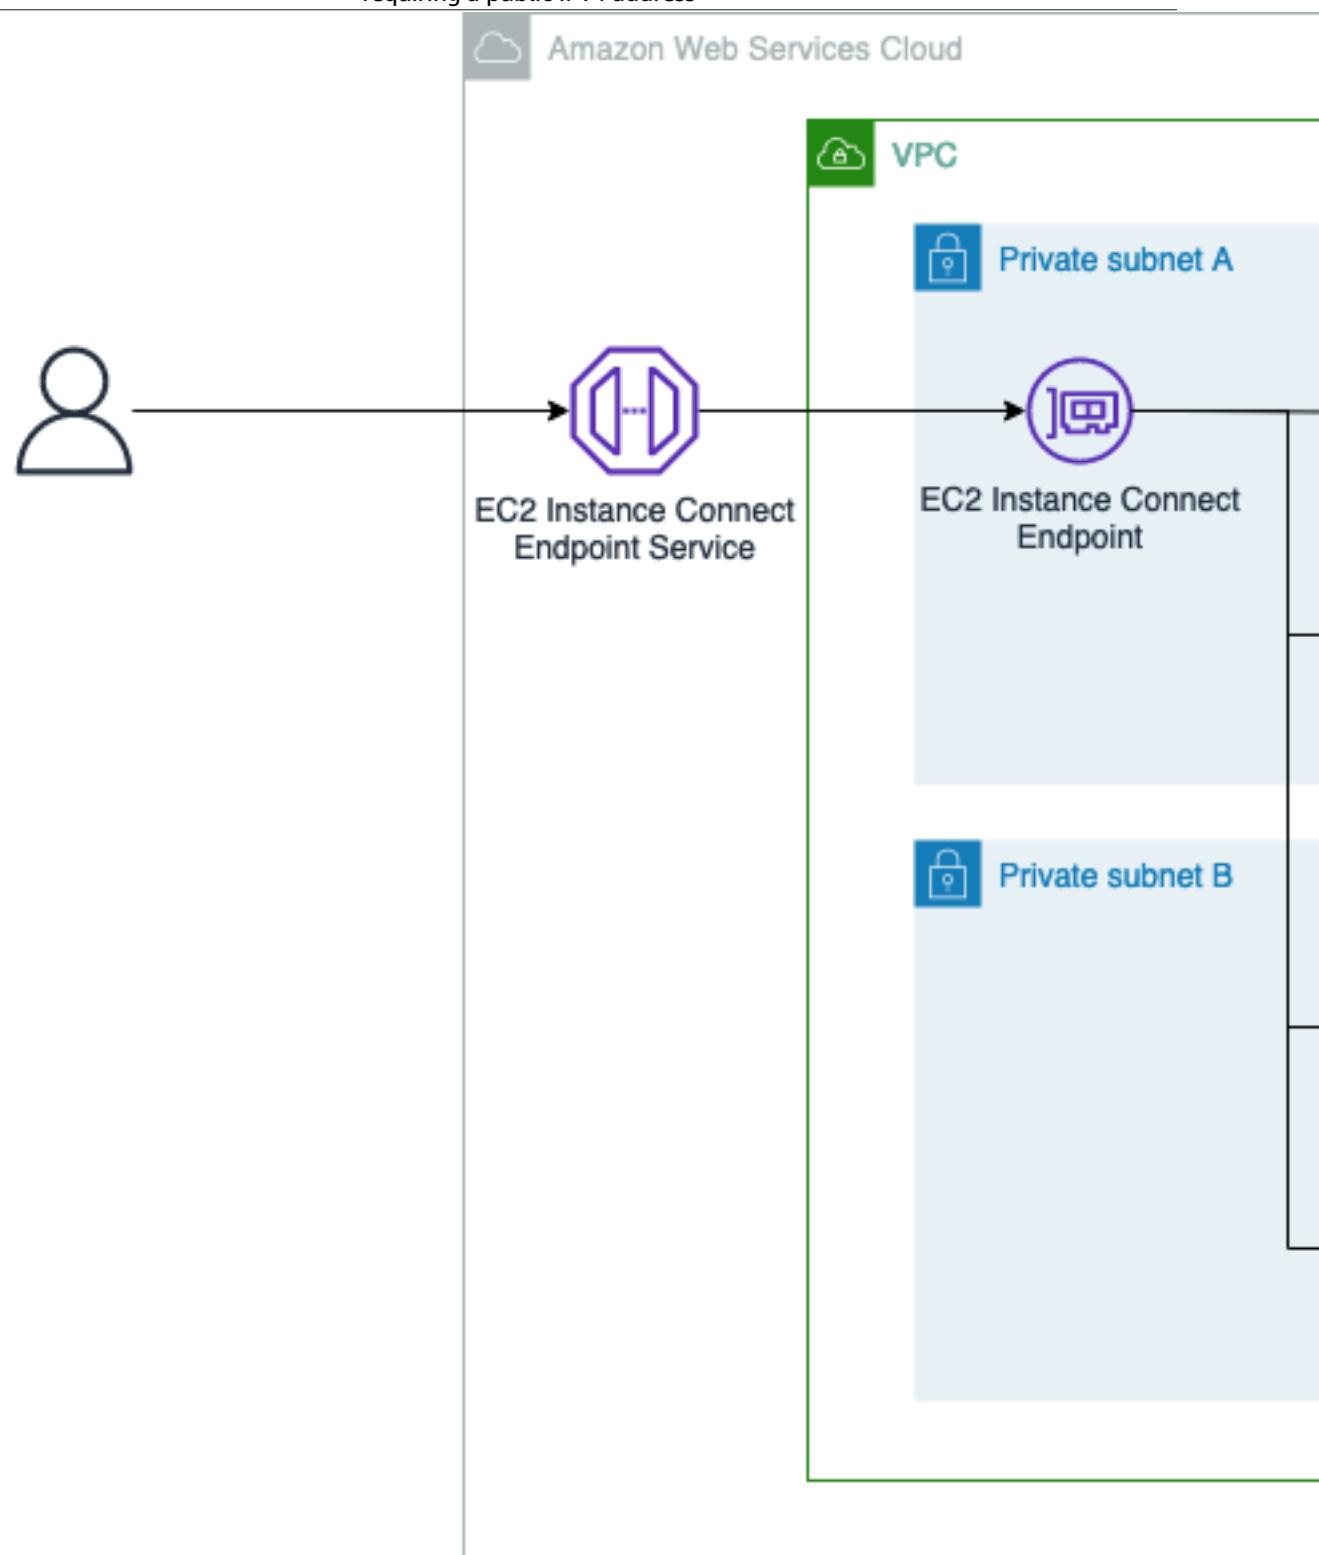

First, you create an EC2 Instance Connect Endpoint in a [subnet](#) in your virtual private cloud (VPC). Then, when you want to connect to an instance, you specify the ID of the instance. You can optionally provide the EC2 Instance Connect Endpoint. The endpoint acts as a private tunnel to the instance.

Once you create an EC2 Instance Connect Endpoint in a subnet, you can use the endpoint to connect to any instance in any subnet in your VPC provided your VPC is configured to allow subnets to communicate.

Note

If you use an EC2 Instance Connect Endpoint in one subnet to connect to an instance in another subnet that is in a different Availability Zone, there is an [additional charge for data transfer](#) across Availability Zones.

The following image shows a single VPC with two private subnets. Private subnet A has an EC2 Instance Connect Endpoint, but Private subnet B does not. A user from the internet uses the EC2 Instance Connect Endpoint in Private subnet A to connect to their instances that are located in both the private subnets. The VPC is configured to allow the subnets to communicate.

Access to create and connect to EC2 Instance Connect Endpoints is controlled by [IAM permissions \(p. 643\)](#). You can [configure additional security group rules \(p. 646\)](#) on your instances to

restrict inbound traffic. For example, you can use inbound rules on your instances to only allow traffic on management ports from the EC2 Instance Connect Endpoint.

All attempts to connect to instances, both successful and unsuccessful, are logged to [CloudTrail \(p. 657\)](#).

Contents

- [Grant IAM permissions to use EC2 Instance Connect Endpoint \(p. 643\)](#)
- [Security groups for EC2 Instance Connect Endpoint \(p. 646\)](#)
- [Create an EC2 Instance Connect Endpoint \(p. 647\)](#)
- [Connect using EC2 Instance Connect Endpoint to an instance \(p. 652\)](#)
- [Log connections established over EC2 Instance Connect Endpoint \(p. 657\)](#)
- [Remove EC2 Instance Connect Endpoint \(p. 659\)](#)
- [Service-linked role for EC2 Instance Connect Endpoint \(p. 660\)](#)
- [Quotas \(p. 663\)](#)

Grant IAM permissions to use EC2 Instance Connect Endpoint

To create or use an EC2 Instance Connect Endpoint, you must create an IAM policy that grants your users permissions for the following:

- Create, describe, and delete EC2 Instance Connect Endpoints
- Use the `ec2-instance-connect:OpenTunnel` action to use EC2 Instance Connect Endpoint to connect to instances

For information about creating IAM policies, see [Creating IAM policies](#) in the *IAM User Guide*.

Example IAM policies for EC2 Instance Connect Endpoint

- [Allow users to create, describe, and delete EC2 Instance Connect Endpoints \(p. 643\)](#)
- [Allow users to use EC2 Instance Connect Endpoint to connect to instances \(p. 644\)](#)
- [Allow users to connect only from a specified source IP address range \(p. 646\)](#)

Allow users to create, describe, and delete EC2 Instance Connect Endpoints

To create an EC2 Instance Connect Endpoint, users require permissions for the following actions:

- `ec2:CreateInstanceConnectEndpoint`
- `ec2:CreateNetworkInterface`
- `ec2:CreateTags`
- `iam:CreateServiceLinkedRole`

To describe and delete EC2 Instance Connect Endpoints, users require permissions for the following actions:

- `ec2:DescribeInstanceConnectEndpoints`
- `ec2:DeleteInstanceConnectEndpoint`

You can create a policy that grants permission to create, describe, and delete EC2 Instance Connect Endpoints in all subnets. Alternatively, you can restrict actions for specified subnets only by specifying

the subnet ARNs as the allowed Resource or by using the ec2:SubnetID condition key. You can also use the aws:ResourceTag condition key to explicitly allow or deny endpoint creation with certain tags. For more information, see [Policies and permissions in IAM](#) in the *IAM User Guide*.

Example IAM policy

In the following example IAM policy, the Resource section grants permission to create and delete endpoints in all subnets, specified by the asterisk (*). The ec2:Describe* API actions do not support resource-level permissions. Therefore, the * wildcard is necessary in the Resource element.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "GrantAllActionsInAllSubnets",  
            "Action": [  
                "ec2:CreateInstanceConnectEndpoint",  
                "ec2>DeleteInstanceConnectEndpoint",  
                "ec2>CreateNetworkInterface",  
                "ec2>CreateTags",  
                "iam>CreateServiceLinkedRole"  
            ],  
            "Effect": "Allow",  
            "Resource": "arn:aws:ec2:<region>:<account-id>:subnet/*"  
        },  
        {  
            "Action": [  
                "ec2>CreateNetworkInterface"  
            ],  
            "Effect": "Allow",  
            "Resource": "arn:aws:ec2:::security-group/*"  
        },  
        {  
            "Sid": "DescribeInstanceConnectEndpoints",  
            "Action": [  
                "ec2:DescribeInstanceConnectEndpoints"  
            ],  
            "Effect": "Allow",  
            "Resource": "*"  
        }  
    ]  
}
```

Allow users to use EC2 Instance Connect Endpoint to connect to instances

The ec2-instance-connect:OpenTunnel action grants permission to establish a TCP connection to an instance to connect over the EC2 Instance Connect Endpoint. You can specify the EC2 Instance Connect Endpoint to use. Alternatively, a Resource with an asterisk (*) allows users to use any available EC2 Instance Connect Endpoint. You can also restrict access to instances based on the presence or absence of resource tags as condition keys.

Conditions

- **ec2-instance-connect:remotePort** – Specifies the port on the instance that can be used to establish a TCP connection. When this condition key is used, attempting to connect to an instance on any other port other than the port specified in the policy results in a failure.
- **ec2-instance-connect:privateIpAddress** – Specifies the destination private IP address associated with the instance that you want to establish a TCP connection with. You can specify a single IP address, such as 10.0.0.1/32, or a range of IPs through CIDRs, such as 10.0.1.0/28. When this condition key is used, attempting to connect to an instance with a different private IP address or outside the CIDR range results in a failure.

-
- **ec2-instance-connect:maxTunnelDuration** – Specifies the maximum duration for an established TCP connection. The unit is seconds and the duration ranges from a minimum of 1 second to a maximum of 3,600 seconds (1 hour). If the condition is not specified, the default duration is set to 3,600 seconds (1 hour). Attempting to connect to an instance for longer than the specified duration in the IAM policy or for longer than the default maximum results in a failure. The connection is disconnected after the specified duration.

If `maxTunnelDuration` is specified in the IAM policy and the value specified is less than 3,600 seconds (the default), then you must specify `--max-tunnel-duration` in the command when connecting to an instance. For information about how to connect to an instance, see [Connect using EC2 Instance Connect Endpoint to an instance \(p. 652\)](#).

A user can also be granted access to establish connections to instances based on the presence of resource tags on the EC2 Instance Connect Endpoint. For more information, see [Policies and permissions in IAM](#) in the *IAM User Guide*.

Example IAM policy

The following example IAM policy allows an IAM principal to connect to an instance using only the specified EC2 Instance Connect Endpoint, identified by the specified endpoint ID `eice-123456789abcdef`. The connection is successfully established only if all the conditions are satisfied, for example, if the SSH connection is established on port 22 of the instance, if the private IP address of the instance lies within the range of `10.0.1.0/31` (between `10.0.1.0` and `10.0.1.1`), and the `maxTunnelDuration` is less than or equal to 3600 seconds. The connection is disconnected after 3600 seconds (1 hour).

The `ec2:Describe*` API actions do not support resource-level permissions. Therefore, the `*` wildcard is necessary in the `Resource` element.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "EC2InstanceConnect",  
            "Action": "ec2-instance-connect:OpenTunnel",  
            "Effect": "Allow",  
            "Resource": "arn:aws:ec2:region:account-id:instance-connect-  
            endpoint/eice-123456789abcdef",  
            "Condition": {  
                "NumericEquals": {  
                    "ec2-instance-connect:remotePort": "22"  
                },  
                "IpAddress": {  
                    "ec2-instance-connect:privateIpAddress": "10.0.1.0/31"  
                },  
                "NumericLessThanEquals": {  
                    "ec2-instance-connect:maxTunnelDuration": "3600"  
                }  
            }  
        },  
        {  
            "Sid": "Describe",

            "Resource": "*"  
        }  
    ]  
}
```

Allow users to connect only from a specified source IP address range

The following example IAM policy allows an IAM principal to connect to an instance on condition they are connecting from an IP address within the IP address range specified in the policy. If the IAM principal calls OpenTunnel from an IP address not within 192.0.2.0/24 (the example IP address range in this policy), the response will be Access Denied. For more information, see [aws:SourceIp](#) in the *IAM User Guide*.

}
```

Security groups for EC2 Instance Connect Endpoint

The EC2 Instance Connect Endpoint and the instance that you want to connect to are each assigned security groups. We recommend that you configure the [security group rules \(p. 1676\)](#) in the way described in this topic.

Topics

- [EC2 Instance Connect Endpoint security group rule \(p. 646\)](#)
- [Instance security group rule \(p. 647\)](#)
- [Example \(p. 647\)](#)

EC2 Instance Connect Endpoint security group rule

When you create the EC2 Instance Connect Endpoint, if you don't specify a security group, the default security group for the VPC is assigned. The default outbound rule allows all outbound traffic to all destinations. To limit connectivity to only the instances in the VPC, we recommend that the outbound rule only allows traffic to the specified destination.

Recommended outbound rule

- Allow outbound traffic to the specified destination (a security group or the VPC CIDR, depending on your security needs).

Instance security group rule

The instance needs at least one inbound rule to allow traffic from the EC2 Instance Connect Endpoint.

Recommended inbound rules

Specify one or more of the following rules, depending on your security needs and whether client IP preservation is enabled:

- Allow inbound traffic from the EC2 Instance Connect Endpoint security group.
- Allow inbound traffic from the client IP address.
- Allow inbound traffic from the VPC CIDR so that any instances in the VPC can send traffic to the destination instance.

The inbound rule that you specify is dependent on whether the EC2 Instance Connect Endpoint is configured to enable client IP preservation. Not all instance types support client IP preservation. For more information, see [Limitations \(p. 652\)](#).

The following table lists the security group rules for the instance that can be configured depending on the value set for `preserveClientIp`.

Client IP preservation	Supported security group rules for the instance
<code>preserveClientIp=false</code>	<ul style="list-style-type: none">• Allow inbound traffic from the EC2 Instance Connect Endpoint security group.• Allow inbound traffic from the VPC CIDR.
<code>preserveClientIp=true</code>	<ul style="list-style-type: none">• Allow inbound traffic from the EC2 Instance Connect Endpoint security group.• Allow inbound traffic from the client IP address.

Example

In the following image, the EC2 Instance Connect Endpoint is assigned the security group **EIC Endpoint Security Group**. The **EIC Endpoint Security Group** has one outbound rule that allows TCP traffic to the **Development Security Group**. This configuration means that the EC2 Instance Connect Endpoint can only send traffic to instances that are assigned the **Development Security Group**. In the image, the instance is assigned the **Development Security Group**, which means that, in this example, the EC2 Instance Connect Endpoint can send TCP traffic to the instance.

Create an EC2 Instance Connect Endpoint

You can create an EC2 Instance Connect Endpoint in a subnet in your VPC. You can then use the EC2 Instance Connect Endpoint to connect to instances in your VPC without requiring the instances to have a public IPv4 address.

EC2 Instance Connect Endpoint supports client IP preservation. You can configure the EC2 Instance Connect Endpoint to use your client's IP address as the source (`preserveClientIp` parameter is `true`) when connecting to an instance.

When you create an EC2 Instance Connect Endpoint, a service-linked role is automatically created for the Amazon EC2 service in AWS Identity and Access Management (IAM). Amazon EC2 uses the service-

linked role to provision network interfaces in your account, which are required when creating EC2 Instance Connect Endpoints. For more information, see [Service-linked role for EC2 Instance Connect Endpoint \(p. 660\)](#).

Prerequisites

You must have the required IAM permissions to create an EC2 Instance Connect Endpoint. For more information, see [Allow users to create, describe, and delete EC2 Instance Connect Endpoints \(p. 643\)](#).

Create an EC2 Instance Connect Endpoint

Use one of the following methods to create an EC2 Instance Connect Endpoint.

Console

To create an EC2 Instance Connect Endpoint

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the left navigation pane, choose **Endpoints**.
3. Choose **Create endpoint**, and then complete the settings in the dialog box, as follows:

Amazon Elastic Compute Cloud
User Guide for Windows Instances
Connect to instances without
requiring a public IPv4 address

Endpoint settings

Name tag - optional

Creates a tag with a key of 'Name' and a value that you specify.

my-endpoint

Service category

Select the service category

AWS services

Services provided by Amazon

PrivateLink Ready partner services

Services with an AWS Service Ready designation

AWS Marketplace services

Services that you've purchased through AWS Marketplace

EC2 Instance Connect Endpoint

An elastic network interface that

allow you to connect to resources
in a private subnet

Other endpoint services

Find services shared with you by
service name

VPC

Select the VPC in which to create the endpoint

VPC

The VPC in which to create your endpoint.

vpc-92304aeb

Additional settings

Preserve Client IP

EC2 Instance Connect Endpoint supports client IP preservation. You can configure the EC2 Instance Connect Endpoint to use your client's IP address as the source (preserveClientIp parameter is true) when connecting to a resource.

Security groups (2)

Tags

Key

Value - optional

Name

my-endpoint

Remove

Add new tag

You can add 49 more tags.

-
- a. (Optional) For **Name tag**, enter a name for the endpoint.
 - b. For **Service category**, choose **EC2 Instance Connect Endpoint**.
 - c. For **VPC**, select the VPC in which to create the endpoint.
 - d. Expand **Additional settings**, and for **Preserve Client IP** do one of the following:
 - If you want your client's IP address to be used as the source when you connect to an instance, select the check box.

Note: When **Preserve Client IP** is turned on, your instance's security group must allow traffic from your client IP address. For more information, see [Instance security group rule \(p. 647\)](#).

- e. (Optional) For **Security groups**, select the security group to associate with the endpoint. If you don't select a security group, the default security group for your VPC will be associated with the endpoint. For more information, see [Security groups for EC2 Instance Connect Endpoint \(p. 646\)](#).
- f. For **Subnet**, select the subnet in which to create the endpoint.
- g. (Optional) To add a tag, choose **Add new tag** and enter the tag key and the tag value.
- h. Choose **Create endpoint**.

The initial status is **Pending**. Before you can connect to an instance using this endpoint, wait until the status is **Available**. This can take a few minutes. To monitor the endpoint status, see [Describe an EC2 Instance Connect Endpoint \(p. 651\)](#).

AWS CLI

To create an EC2 Instance Connect Endpoint

Use the [create-instance-connect-endpoint](#) AWS CLI command and specify the subnet in which to create your EC2 Instance Connect Endpoint. Make sure you're using the latest version of the AWS CLI.

```
aws ec2 create-instance-connect-endpoint --region us-east-1 --subnet-id subnet-0123456789example
```

Example output

```
{  
    "VpcId": "vpc-0123abcd",  
    "InstanceConnectEndpointArn": "arn:aws:ec2:us-east-1:111111111111:instance-connect-endpoint/eice-0123456789example",  
    "AvailabilityZone": "us-east-1a",  
    "NetworkInterfaceIds": [  
        "eni-0123abcd"  
    ],  
    "PreserveClientIp": true,  
    "Tags": [],  
    "FipsDnsName": "eice-0123456789example.0123abcd.fips.ec2-instance-connect-endpoint.us-east-1.amazonaws.com",  
    "StateMessage": "",  
    "State": "create-complete",  
    "DnsName": "eice-0123456789example.0123abcd.ec2-instance-connect-endpoint.us-east-1.amazonaws.com",  
    "SubnetId": "subnet-0123abcd",  
    "OwnerId": "111111111111",  
    "SecurityGroupIds": [  
        "sg-0123abcd"  
    ]  
}
```

```
"sg-0123abcd"  
],  
"InstanceConnectEndpointId": "eice-0123456789example",  
"CreatedAt": "2023-04-07T15:43:53.000Z"  
}
```

The initial value for the State field is `create-in-progress`. Before you can connect to an instance using this endpoint, wait until the state is `create-complete`. This can take a few minutes. To monitor the endpoint state, see [Describe an EC2 Instance Connect Endpoint \(p. 651\)](#).

Describe an EC2 Instance Connect Endpoint

Use one of the following methods to describe an EC2 Instance Connect Endpoint.

Console

To view an EC2 Instance Connect Endpoint

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the left navigation pane, choose **Endpoints**.
3. Find the endpoint in the table and select it to view its details. To use the endpoint to connect to an instance, the **Status** field must display **Available**.

AWS CLI

To describe an EC2 Instance Connect Endpoint

Use the [describe-instance-connect-endpoints](#) AWS CLI command and specify the EC2 Instance Connect Endpoint ID.

```
aws ec2 describe-instance-connect-endpoints --region us-east-1 --instance-connect-  
endpoint-ids eice-0123456789example
```

Example output - To use the endpoint for connecting to an instance, the State field must show `create-complete`.

```
{  
    "InstanceConnectEndpoints": [  
        {  
            "OwnerId": "111111111111",  
            "InstanceConnectEndpointId": "eice-0123456789example",  
            "InstanceConnectEndpointArn": "arn:aws:ec2:us-east-1:111111111111:instance-  
connect-endpoint/eice-0123456789example",  
            "State": "create-complete",  
            "StateMessage": "",  
            "DnsName": "eice-0123456789example.b67b86ba.ec2-instance-connect-  
endpoint.us-east-1.amazonaws.com",  
            "NetworkInterfaceIds": [  
                "eni-0123456789example"  
            ],  
            "VpcId": "vpc-0123abcd",  
            "AvailabilityZone": "us-east-1d",  
            "CreatedAt": "2023-02-07T12:05:37+00:00",  
            "SubnetId": "subnet-0123abcd",  
            "Tags": []  
        }  
    ]  
}
```

Connect using EC2 Instance Connect Endpoint to an instance

EC2 Instance Connect Endpoint allows you to connect to an instance without requiring the instance to have a public IPv4 address. You can connect to any instances that support TCP.

To connect to an instance, specify the instance ID. You can optionally provide the EC2 Instance Connect Endpoint.

Limitations

- Only ports 22 and 3389 are supported.
- EC2 Instance Connect Endpoint doesn't support connections to an instance using IPv6 addresses.
- When client IP preservation is enabled, the instance to connect to must be in the same VPC as the EC2 Instance Connect Endpoint.
- Client IP preservation is not supported when traffic is routed through an AWS Transit Gateway.
- The following instance types do not support client IP preservation: C1, CG1, CG2, G1, G2, HI1, M1, M2, M3, and T1. If you are using these instance types, set the `preserveClientIp` parameter to `false`, otherwise attempting to connect to these instance types using EC2 Instance Connect Endpoint will fail. For more information about the `preserveClientIp` parameter, see step 3.d in the [Create an EC2 Instance Connect Endpoint \(p. 648\)](#) console procedure.

Prerequisites

- You must have the required IAM permission to connect to an EC2 Instance Connect Endpoint. For more information, see [Allow users to use EC2 Instance Connect Endpoint to connect to instances \(p. 644\)](#).
- The EC2 Instance Connect Endpoint must be in the **Available** (console) or `create-complete` (AWS CLI) state. To monitor the endpoint state, see [Describe an EC2 Instance Connect Endpoint \(p. 651\)](#).
- Ensure that the security group of the instance that you want to connect to is configured correctly for inbound traffic. For more information, see [Instance security group rule \(p. 647\)](#).
- If you're using the AWS CLI, make sure that you have configured the AWS CLI, including the credentials that it uses, and that you're using the latest version of the AWS CLI. For more information, see [Installing or updating the latest version of the AWS CLI](#) and [Configuring the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

Connection options

- [Connect to your Linux instance using the Amazon EC2 console \(p. 652\)](#)
- [Connect to your Linux instance using SSH \(p. 655\)](#)
- [Connect to your Windows instance using RDP \(p. 656\)](#)
- [Troubleshoot \(p. 657\)](#)

Connect to your Linux instance using the Amazon EC2 console

You can connect to an instance using the Amazon EC2 console by selecting the instance from the console and choosing to connect using EC2 Instance Connect, which handles the permissions and provides a successful connection.

To connect to your instance using the browser-based client from the Amazon EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.

3. Select the instance, choose **Connect**, and then do the following:

Connect to instance Info

Connect to your instance i-00ce5b4dc72ef77ca (test-eic) using any of the methods listed below.

EC2 Instance Connect

Session Manager

SSH client

Instance ID

[i-00ce5b4dc72ef77ca \(test-eic\)](#)

Connection Type

Connect using EC2 Instance Connect

Connect using the EC2 Instance Connect browser-based client, with a public IPv4 address.

Private IP address

172.31.0.63

User name

Enter the user name defined in the AMI used to launch the instance. If you didn't change it, enter ec2-user.

ec2-user

Max tunnel duration (seconds)

The maximum allowed duration of the SSH connection. Must comply with the maximum allowed duration of the EC2 Instance Connect endpoint.

3600

Min 1 second. Max 3600 seconds (1 hour).

EC2 Instance Connect Endpoint

Only endpoints that have completed the creation process can be selected.

eice-073b6240d11a242c9

654

-
- a. Choose the **EC2 Instance Connect** tab.
 - b. For **Connection type**, choose **Connect using EC2 Instance Connect Endpoint**.
 - c. For **User name**, verify the user name.
 - d. For **Max tunnel duration (seconds)**, enter the maximum allowed duration for the SSH connection.

The duration must comply with the maxTunnelDuration condition specified in the IAM policy. If you don't have access to the IAM policy, ask your administrator to verify it. If maxTunnelDuration is not specified in the IAM policy, enter the default, which is **3600** seconds (1 hour).

- e. For **EC2 Instance Connect Endpoint**, choose the EC2 Instance Connect Endpoint in the instance's VPC.
- f. Choose **Connect** to open a terminal window.

Connect to your Linux instance using SSH

You can use SSH to connect to your Linux instance, and use the `open-tunnel` command to establish a private tunnel. You can use `open-tunnel` in single connection or multi-connection mode.

The following examples use [OpenSSH](#). You can use any other SSH client that supports a proxy mode.

Single connection

To allow only a single connection to an instance using SSH and the `open-tunnel` command

Use `ssh` and the [open-tunnel](#) AWS CLI command as follows. The `-o` proxy command encloses the `open-tunnel` command that creates the private tunnel to the instance.

```
ssh -i my-key-pair.pem ec2-user@i-0123456789example \
    -o ProxyCommand='aws ec2-instance-connect open-tunnel --instance-
id i-0123456789example'
```

For:

- `-i` – Specify the key pair that was used to launch the instance.
- `ec2-user@i-0123456789example` – Specify the username of the AMI that was used to launch the instance, and the instance ID.
- `--instance-id` – Specify the ID of the instance to connect to. Alternatively, specify `%h`, which extracts the instance ID from the user.

Multi-connection

To allow multiple connections to an instance, first run the [open-tunnel](#) AWS CLI command to start listening for new TCP connections, and then use `ssh` to create a new TCP connection and a private tunnel to your instance.

To allow multiple connections to your instance using SSH and the `open-tunnel` command

1. Run the following command to start listening for new TCP connections on the specified port on your local machine.

```
aws ec2-instance-connect open-tunnel \
```

Amazon Elastic Compute Cloud
User Guide for Windows Instances
Connect to instances without
requiring a public IPv4 address

```
--instance-id i-0123456789example \  
--local-port 8888
```

Expected output

```
Listening for connections on port 8888.
```

2. In a *new terminal window*, run the following ssh command to create a new TCP connection and a private tunnel to your instance.

```
ssh -i my-key-pair.pem ec2-user@localhost -p 8888
```

Expected output – In the *first* terminal window, you'll see the following:

```
[1] Accepted new tcp connection, opening websocket tunnel.
```

You might also see the following:

```
[1] Closing tcp connection.
```

Connect to your Windows instance using RDP

You can use Remote Desktop Protocol (RDP) over EC2 Instance Connect Endpoint to connect to a Windows instance without a public IPv4 address or public DNS name.

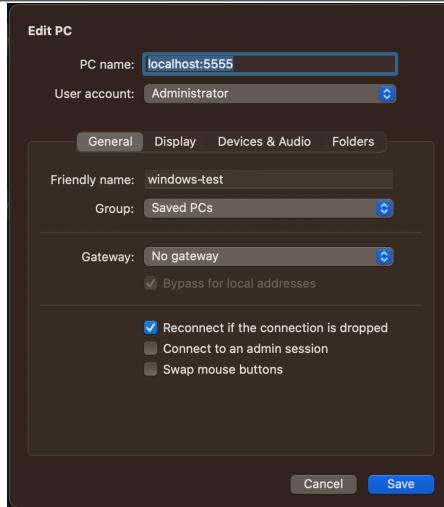

To connect to your Windows instance using an RDP client

1. Complete Steps 1 – 6 in [Connect to your Windows instance using RDP](#) in the *Amazon EC2 User Guide for Windows Instances*. After downloading the RDP desktop file at Step 6, you'll get an **Unable to connect** message, which is to be expected because your instance does not have a public IP address.
2. Run the following command to establish a private tunnel to the VPC in which the instance is located. **--remote-port** must be 3389 because RDP uses port 3389 by default.

```
aws ec2-instance-connect open-tunnel \  
--instance-id i-0123456789example \  
--remote-port 3389 \  
--local-port any-port
```

3. In your **Downloads** folder, find the RDP desktop file that you downloaded, and drag it onto the RDP client window.
4. Right-click the RDP desktop file and choose **Edit**.
5. In the **Edit PC** window, for **PC name** (the instance to connect to), enter `localhost:local-port`, where **local-port** uses the same value as in the previous step, and then choose **Save**.

Note that the following screenshot of the **Edit PC** window is from Microsoft Remote Desktop on a Mac. If you are using a Windows client, the window might be different.

6. In the RDP client, right-click the PC (that you just configured) and choose **Connect** to connect to your instance.
7. At the prompt, enter the decrypted password for the administrator account.

Troubleshoot

Use the following information to help diagnose and fix issues that you might encounter when using EC2 Instance Connect Endpoint to connect an instance.

Can't connect to your instance

The following are common reasons why you might not be able to connect to your instance.

- Security groups – Check the security groups assigned to the EC2 Instance Connect Endpoint and your instance. For more information about the required security group rules, see [Security groups for EC2 Instance Connect Endpoint \(p. 646\)](#).
- Instance state – Verify that your instance is in the running state.
- Key pair – If the command you're using to connect requires a private key, verify that your instance has a public key and that you have the corresponding private key.
- IAM permissions – Verify that you have the required IAM permissions. For more information, see [Grant IAM permissions to use EC2 Instance Connect Endpoint \(p. 643\)](#).

For more troubleshooting tips, see [Troubleshoot connecting to your Windows instance \(p. 2119\)](#).

ErrorCode: AccessDeniedException

If you receive an `AccessDeniedException` error, and the `maxTunnelDuration` condition is specified in the IAM policy, be sure to specify the `--max-tunnel-duration` parameter when connecting to an instance. For more information about this parameter, see [open-tunnel](#) in the *AWS CLI Command Reference*.

Log connections established over EC2 Instance Connect Endpoint

You can log resource operations and audit connections established over the EC2 Instance Connect Endpoint with AWS CloudTrail logs.

For more information about using AWS CloudTrail with Amazon EC2, see [Log Amazon EC2 and Amazon EBS API calls with AWS CloudTrail \(p. 1216\)](#).

Log EC2 Instance Connect Endpoint API calls with AWS CloudTrail

EC2 Instance Connect Endpoint resource operations are logged to CloudTrail as management events. When the following API calls are made, the activity is recorded as a CloudTrail event in **Event history**:

- `CreateInstanceConnectEndpoint`
- `DescribeInstanceConnectEndpoints`
- `DeleteInstanceConnectEndpoint`

You can view, search, and download recent events in your AWS account. For more information, see [Viewing events with CloudTrail Event history](#) in the *AWS CloudTrail User Guide*.

Use AWS CloudTrail to audit users who connect to an instance using EC2 Instance Connect Endpoint

Connection attempts to instances via EC2 Instance Connect Endpoint are logged in CloudTrail in **Event history**. When a connection to an instance is initiated through an EC2 Instance Connect Endpoint, the connection is logged as a CloudTrail management event with the `eventName` of `OpenTunnel`.

You can create Amazon EventBridge rules that route the CloudTrail event to a target. For more information, see the [Amazon EventBridge User Guide](#).

The following is an example of an `OpenTunnel` management event that was logged in CloudTrail.

```
{  
    "eventVersion": "1.08",  
    "userIdentity": {  
        "type": "IAMUser",

```

Remove EC2 Instance Connect Endpoint

To remove EC2 Instance Connect Endpoint from your VPC, delete the endpoint that was created in a subnet.

When you delete an EC2 Instance Connect Endpoint, it first enters the **Deleting** (console) or **delete-in-progress** (AWS CLI) state, and then the **delete-complete** (AWS CLI) state. In the console, a deleted endpoint no longer appears. If the delete action fails, the state is **delete-failed**, and the **Status message** (console) or **StateMessage** (AWS CLI) provides the failure reason.

Use one of the following methods to delete an EC2 Instance Connect Endpoint.

Console

To delete an EC2 Instance Connect Endpoint

1. Open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. In the left navigation pane, choose **Endpoints**.
3. Select the endpoint.
4. Choose **Actions, Delete VPC endpoints**.
5. When prompted for confirmation, enter **delete**.
6. Choose **Delete**.

AWS CLI

To delete an EC2 Instance Connect Endpoint

Use the [delete-instance-connect-endpoints](#) AWS CLI command and specify the ID of the EC2 Instance Connect Endpoint to delete.

```
aws ec2 delete-instance-connect-endpoint --instance-connect-endpoint-
id eice-03f5e49b83924bbc7
```

Example output

```
{
    "InstanceConnectEndpoint": {
        "OwnerId": "111111111111",
        "InstanceConnectEndpointId": "eice-0123456789example",
        "InstanceConnectEndpointArn": "arn:aws:ec2:us-east-1:111111111111:instance-
connect-endpoint/eice-0123456789example",
        "State": "delete-in-progress",
        "StateMessage": "",
        "NetworkInterfaceIds": [],
        "VpcId": "vpc-0123abcd",
        "AvailabilityZone": "us-east-1d",
        "CreatedAt": "2023-02-07T12:05:37+00:00",
        "SubnetId": "subnet-0123abcd"
    }
}
```

Service-linked role for EC2 Instance Connect Endpoint

Amazon EC2 uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to Amazon EC2. Service-linked roles are predefined by Amazon EC2 and include all the permissions that Amazon EC2 requires to call other AWS services on your behalf. For more information, see [Using service-linked roles](#) in the *IAM User Guide*.

When you create an EC2 Instance Connect Endpoint, the service-linked role named **AWSServiceRoleForEC2InstanceConnect** and the managed policy named **EC2InstanceConnectEndpoint** are automatically created in your AWS account, and the managed policy is automatically attached to the service-linked role.

Amazon EC2 uses **AWSServiceRoleForEC2InstanceConnect** to manage network interfaces in your account that are required when creating EC2 Instance Connect Endpoints.

Permissions granted by AWSServiceRoleForEC2InstanceConnect

Amazon EC2 uses **AWSServiceRoleForEC2InstanceConnect** to complete the following actions:

- **ec2:CreateNetworkInterface** – Create network interfaces
- **ec2:DeleteNetworkInterface** – Delete network interfaces
- **ec2:DescribeNetworkInterfaces** – Describe network interfaces
- **ec2:DescribeAvailabilityZones** – Describe Availability Zones
- **ec2:ModifyNetworkInterfaceAttribute** – Disable source and destination checks

Use service-linked roles

EC2 Instance Connect Endpoint uses the service-linked role named **AWSServiceRoleForEC2InstanceConnect** to provision network interfaces in your account that are required to use the service.

If you create an EC2 Instance Connect Endpoint, the **EC2InstanceConnectEndpoint** managed policy is automatically created in your AWS account and attached to the **AWSServiceRoleForEC2InstanceConnect** service-linked role.

Service Linked Roles for EC2 Instance Connect Endpoint

The **AWSServiceRoleForEC2InstanceConnect** service-linked role trusts the following services to assume the role:

- **ec2-instance-connect.amazonaws.com**

The role permissions policy, named **EC2InstanceConnectEndpoint**, allows EC2 Instance Connect Endpoint to complete the following actions on the specified resources:

- Action: **ec2:CreateNetworkInterface** – On all subnets and all network interfaces with the non-null tag key **InstanceConnectEndpointId** to create network interfaces for EC2 Instance Connect Endpoint

-
- Action: `ec2:CreateTags` – On all network interfaces created for an EC2 Instance Connect Endpoint at creation time with the tag key **InstanceConnectEndpointId**
 - Action: `ec2:DeleteNetworkInterface` – On network interfaces created for an EC2 Instance Connect Endpoint with tag key **InstanceConnectEndpointId**
 - Action: `ec2:DescribeNetworkInterfaces` – On network interfaces for an Instance Connect Endpoint
 - Action: `ec2:DescribeAvailabilityZones` – For internal mapping of customer's Availability Zone
 - Action: `ec2:ModifyNetworkInterfaceAttribute` – On all network interfaces to disable source and destination checks

Trust policy

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "ec2-instance-connect.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]

]
```

Creating a service-linked role for EC2 Instance Connect Endpoint

When you create an EC2 Instance Connect Endpoint, the service-linked role **AWSServiceRoleForEC2InstanceConnect** is automatically created for you.

Important

Ensure that the AWS account used to create the EC2 Instance Connect Endpoint has an IAM policy attached to it that permits the **iam:CreateServiceLinkedRole** action.

Editing a service-linked role for EC2 Instance Connect Endpoint

EC2 Instance Connect Endpoint doesn't allow you to edit the **AWSServiceRoleForEC2InstanceConnect** service-linked role.

Deleting a service-linked role for EC2 Instance Connect Endpoint

If you no longer need to use EC2 Instance Connect Endpoint, we recommend that you delete the **AWSServiceRoleForEC2InstanceConnect** service-linked role.

Note

You can delete the service-linked role only after you delete all EC2 Instance Connect Endpoint resources.

Use the AWS CLI to delete the service-linked role. For more information, see [Deleting a service-linked role](#) in the *IAM User Guide*.

Follow these steps to delete the service-linked role using the AWS CLI:

1. Delete all EC2 Instance Connect Endpoints using the `delete-instance-connect-endpoint` command, this will also remove the associated resources.
2. Delete the service linked role using the `delete-service-linked-role` command. Deleting the service-linked role will also delete the associated managed policy.

EC2 Instance Connect Endpoint supports using the **AWSServiceRoleForEC2InstanceConnect** service-linked role in every AWS Region where the service is available.

AWS managed policies for EC2 Instance Connect Endpoint

AWS managed policy: EC2InstanceConnectEndpoint

This policy is attached to a service-linked role that allows EC2 Instance Connect Endpoint to perform actions on your behalf. For more information, see [EC2InstanceConnectEndpoint \(p. 660\)](#).

To view the permissions for this policy, see [Ec2InstanceConnectEndpoint](#) in the AWS Management Console.

EC2 Instance Connect Endpoint updates to AWS managed policies

View details about updates to AWS managed policies for EC2 Instance Connect Endpoint since this service began tracking these changes.

Change	Description	Date
EC2 Instance Connect Endpoint started tracking changes	EC2 Instance Connect Endpoint started tracking changes for its AWS managed policies.	June 13, 2023

Quotas

EC2 Instance Connect Endpoint is specifically for management traffic use cases. Each EC2 Instance Connect Endpoint can support up to 20 concurrent connections. You can create a maximum number of EC2 Instance Connect Endpoints per AWS Region as follows:

- 5 EC2 Instance Connect Endpoints per AWS account per AWS Region
- 1 EC2 Instance Connect Endpoint per VPC
- 1 EC2 Instance Connect Endpoint per subnet

Note

EC2 Instance Connect Endpoint is not intended for high volume data transfers. High volume data transfers are throttled.

Connect your EC2 instance to an AWS resource

After you launch an instance, you can connect it to one or more AWS resources.

This section describes how to automatically connect an Amazon EC2 instance to an Amazon RDS database.

Automatically connect an EC2 instance to an RDS database

You can use the automatic connection functionality in the Amazon EC2 console to quickly connect one or more EC2 instances to an RDS database to allow traffic between them.

For more information, see [How the connection is automatically configured \(p. 666\)](#). For a detailed walkthrough, which includes other ways to connect an EC2 instance and an RDS database, see [Tutorial: Connect an Amazon EC2 instance to an Amazon RDS database \(p. 667\)](#).

Topics

- [Costs \(p. 664\)](#)
- [Prerequisites \(p. 664\)](#)
- [Automatically connect an instance and a database \(p. 664\)](#)
- [How the connection is automatically configured \(p. 666\)](#)

Costs

While there is no charge to automatically connect your EC2 instance to an RDS database, you are charged for the underlying services. Data transfer fees will apply if your EC2 instance and RDS database are in different Availability Zones. For information about data transfer fees, see [Data Transfer](#) on the Amazon EC2 On-Demand Pricing page.

Prerequisites

Before you can automatically connect an EC2 instance to an RDS database, check the following:

- The EC2 instances must be in the **Running** state. You can't connect an EC2 instance if it's in another state.
- The EC2 instances and the RDS database must be in the same virtual private cloud (VPC). The automatic connection feature is not supported if an EC2 instance and RDS database are in different VPCs.

Automatically connect an instance and a database

You can automatically connect an EC2 instance to an RDS database immediately after you've launched your instance, or later.

Automatically connect immediately after launch

Use the following steps to automatically connect an EC2 instance to an RDS database immediately after you've launched the EC2 instance.

To view an animation of these steps, see [View an animation: Automatically connect a newly-launched EC2 instance to an RDS database \(p. 665\)](#).

To automatically connect a newly-launched EC2 instance to an RDS database using the EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the console dashboard, choose **Launch instances**, and then follow the steps to [launch an instance \(p. 554\)](#).
3. On the instance launch confirmation page, choose **Connect an RDS database**.
4. In the **Connect RDS Database** dialog box, do the following:
 - a. For **Database role**, choose either **Cluster** or **Instance**.
 - b. For **RDS database**, select a database to connect to.

Note

The EC2 instances and the RDS database must be in the same VPC in order to connect to each other.

- c. Choose **Connect**.

View an animation: Automatically connect a newly-launched EC2 instance to an RDS database

The screenshot shows the Amazon EC2 console interface. The left sidebar includes sections for New EC2 Experience, EC2 Dashboard, Instances (with sub-options like Instances, Launch Templates, and Spot Requests), Images, Elastic Block Store, Network & Security, and Additional. The main content area has tabs for Resources, Service health, and Zones. Under Resources, it shows EC2 resources in the Europe (Stockholm) Region: 1 Instance (running), 1 Dedicated Host, 0 Elastic IPs, 1 Key pair, 0 Load balancers, 9 Security groups, and 2 Snapshots. Below this is a 'Launch instance' section with a 'Launch instance' button and a note about launching in the Europe (Stockholm) Region. To the right is a 'Service health' table showing the Europe (Stockholm) region is operating normally. The 'Zones' table lists availability zones: eu-north-1a, eu-north-1b, and eu-north-1c, each associated with zone ID eun1-az1, eun1-az2, and eun1-az3 respectively. A 'Migrate a server' section at the bottom uses AWS Application Migration Service to simplify migration.

Automatically connect an existing instance

Use the following steps to automatically connect an existing EC2 instance to an RDS database.

To view an animation of these steps, see [View an animation: Automatically connect an existing EC2 instance to an RDS database \(p. 666\)](#).

To automatically connect an existing EC2 instance to an RDS database using the EC2 console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select one or more EC2 instances to connect to an RDS database, and then choose **Actions**, **Networking**, **Connect RDS database**.

If **Connect RDS database** is not available, check that the EC2 instances are in the **Running** state and that they are in the same VPC.

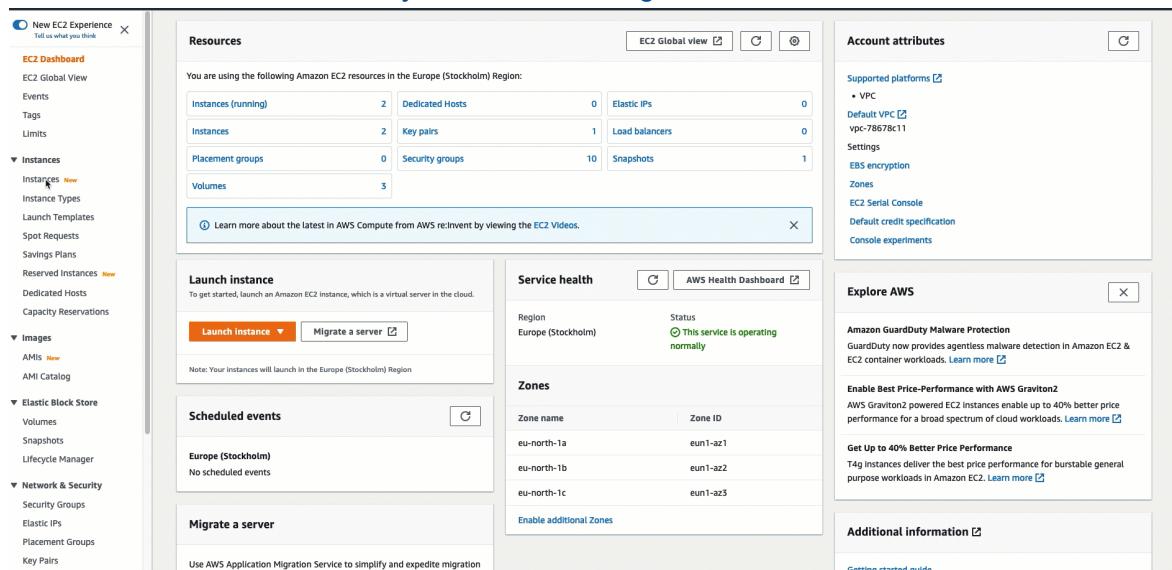

4. In the **Connect RDS Database** dialog box, do the following:
 - a. For **Database role**, choose either **Cluster** or **Instance**.
 - b. For **RDS database**, select a database to connect to.

Note

The EC2 instances and the RDS database must be in the same VPC in order to connect to each other.

- c. Choose **Connect**.

View an animation: Automatically connect an existing EC2 instance to an RDS database

For information about how to use the Amazon RDS console to automatically connect an EC2 instance to an RDS database, see [Configure automatic network connectivity with an EC2 instance](#) in the *Amazon RDS User Guide*.

How the connection is automatically configured

When you use the EC2 console to automatically configure the connection between an EC2 instance and an RDS database to allow traffic between them, the connection is configured by [security groups \(p. 1674\)](#).

The security groups are automatically created and added to the EC2 instance and RDS database, as follows:

- Amazon EC2 creates a security group called **ec2-rds-x** and adds it to the EC2 instance. It has one outbound rule that allows traffic to the database by specifying **rds-ec2-x** (the database security group) as its destination.
- Amazon RDS creates a security group called **rds-ec2-x** and adds it to the database. It has one inbound rule that allows traffic from the EC2 instance by specifying **ec2-rds-x** (the EC2 instance security group) as its source.

The security groups reference each other as the destination and source, and only allow traffic on the database port. You can reuse these security groups so that any database with the **rds-ec2-x** security group can talk to any EC2 instance with the **ec2-rds-x** security group.

The security group names follow a pattern. For the security groups created by Amazon EC2, the pattern is **ec2-rds-x**, and for the security groups created by Amazon RDS, the pattern is **rds-ec2-x**. **x** is a number, which increases by 1 each time a new security group is automatically created.

Tutorial: Connect an Amazon EC2 instance to an Amazon RDS database

Tutorial objective

The objective of this tutorial is to learn how to configure a secure connection between an Amazon EC2 instance and an Amazon RDS database by using the AWS Management Console.

There are different options for configuring the connection. In this tutorial, we explore the following three options:

- [Option 1: Automatically connect your EC2 instance to your RDS database using the EC2 console \(p. 670\)](#)

Use the automatic connection feature in the EC2 console to automatically configure the connection between your EC2 instance and your RDS database to allow traffic between the EC2 instance and the RDS database.

- [Option 2: Automatically connect your EC2 instance to your RDS database using the RDS console \(p. 677\)](#)

Use the automatic connection feature in the RDS console to automatically configure the connection between your EC2 instance and your RDS database to allow traffic between the EC2 instance and the RDS database.

- [Option 3: Manually connect your EC2 instance to your RDS database by mimicking the automatic connection feature \(p. 684\)](#)

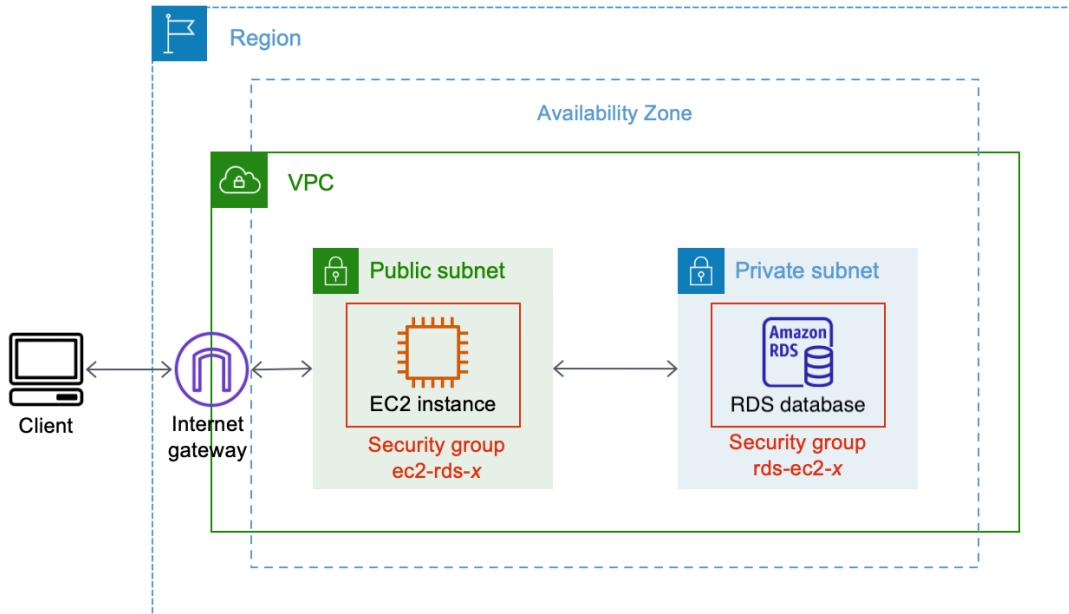

Configure the connection between your EC2 instance to your RDS database by manually configuring and assigning the security groups to reproduce the configuration that is automatically created by the automatic connection feature in Option 1 and Option 2.

Context

As context for why you'd want to configure a connection between your EC2 instance and an RDS database, let's consider the following scenario: Your website presents a form to your users to fill in. You need to capture the form data in a database. You can host your website on an EC2 instance that's been configured as a web server, and you can capture the form data in an RDS database. The EC2 instance and the RDS database need to be connected to each other so that the form data can go from the EC2 instance to the RDS database. This tutorial explains how to configure that connection. Note that this is just one example of a use case for connecting an EC2 instance and an RDS database.

Architecture

The following diagram shows the resources that are created and the architectural configuration that results from completing all the steps in this tutorial.

The diagram illustrates the following resources that you'll create:

- You'll create an EC2 instance and an RDS database in the same AWS Region, VPC, and Availability Zone.
- You'll create the EC2 instance in a public subnet.
- You'll create the RDS database in a private subnet.

When you use the RDS console to create the RDS database and automatically connect the EC2 instance, the VPC, DB subnet group, and public access settings for the database are automatically selected. The RDS database is automatically created in a private subnet within the same VPC as the EC2 instance.

- Internet users can connect to the EC2 instance by using SSH or HTTP/HTTPS via an Internet gateway.
- Internet users cannot connect directly to the RDS database; only the EC2 instance is connected to the RDS database.
- When you use the automatic connection feature to allow traffic between the EC2 instance and the RDS database, the following security groups are automatically created and added:
 - Security group `ec2-rds-x` is created and added to the EC2 instance. It has one outbound rule that references the `rds-ec2-x` security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the `rds-ec2-x` security group.
 - Security group `rds-ec2-x` is created and added to the RDS database. It has one inbound rule that references the `ec2-rds-x` security group as its source. This allows traffic from the EC2 instance with the `ec2-rds-x` security group to reach the RDS database.

By using separate security groups (one for the EC2 instance, and one for the RDS database), you have better control over the security of the instance and the database. If you were to use the same security group on both the instance and the database, and then modified the security group to suit, say, only the database, the modification would affect both the instance and the database. In other words, if you were to use one security group, you could unintentionally modify the security of a resource (either the instance or the database) because you'd forgotten that the security group was attached to it.

The security groups that are automatically created also respect least privilege as they only allow the mutual connection for this workload on the database port by creating a workload-specific security group pair.

Considerations

Consider the following when you complete the tasks in this tutorial:

- **Two consoles** – You will use the following two consoles for this tutorial:
 - Amazon EC2 console – You will use the EC2 console to launch instances, to automatically connect an EC2 instance to an RDS database, and for the manual option to configure the connection by creating the security groups.
 - Amazon RDS console – You will use the RDS console to create an RDS database and to automatically connect an EC2 instance to an RDS database.
- **One VPC** – To use the automatic connection feature, your EC2 instance and your RDS database must be in the same VPC.

If you were to manually configure the connection between your EC2 instance and your RDS database, you could launch your EC2 instance in one VPC and your RDS database in another VPC; however, you'd need to set up additional routing and VPC configuration. This scenario is not covered in this tutorial.

- **One AWS Region** – The EC2 instance and RDS database must be located in the same Region.
- **Two security groups** – The connectivity between the EC2 instance and the RDS database is configured by two security groups—a security group for your EC2 instance, and a security group for your RDS database.

When you use the automatic connection feature in the EC2 console or RDS console to configure the connectivity (Option 1 and Option 2 of this tutorial), the security groups are automatically created and assigned to the EC2 instance and RDS database.

If you do not use the automatic connection feature, you'll need to manually create and assign the security groups. You do this in Option 3 of this tutorial.

Time to complete the tutorial

30 minutes

You can complete the entire tutorial in one sitting, or you can complete it one task at a time.

Costs

By completing this tutorial, you might incur costs for the AWS resources that you create.

You can use Amazon EC2 under the [free tier](#) provided your AWS account is less than 12 months old and you configure your resources according to the free tier requirements.

If your EC2 instance and your RDS database are in different Availability Zones, you will incur data transfer fees. To avoid incurring these fees, the EC2 instance and the RDS database must be in the same Availability Zone. For information about data transfer fees, see [Data Transfer](#) on the Amazon EC2 On-Demand Pricing page.

To prevent incurring costs after you've completed the tutorial, make sure to delete the resources if they are no longer needed. For the steps to delete the resources, see [Clean up \(p. 691\)](#).

Option 1: Automatically connect your EC2 instance to your RDS database using the EC2 console

Objective

The objective of Option 1 is to explore the automatic connection feature in the EC2 console that automatically configures the connection between your EC2 instance and RDS database to allow traffic from the EC2 instance to the RDS database. In Option 3, you'll learn how to manually configure the connection.

Before you begin

You'll need the following to complete this tutorial:

- An RDS database that is in the same VPC as the EC2 instance. You can either use an existing RDS database or follow the steps in Task 1 to create a new RDS database.
- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 2 to create a new EC2 instance.
- Permissions to call the following operations:
 - `ec2:AssociateRouteTable`
 - `ec2:AuthorizeSecurityGroupEgress`
 - `ec2>CreateRouteTable`
 - `ec2:CreateSecurityGroup`
 - `ec2:CreateSubnet`
 - `ec2:DescribeInstances`
 - `ec2:DescribeNetworkInterfaces`
 - `ec2:DescribeRouteTables`
 - `ec2:DescribeSecurityGroups`
 - `ec2:DescribeSubnets`
 - `ec2:ModifyNetworkInterfaceAttribute`
 - `ec2:RevokeSecurityGroupEgress`

Tasks to complete Option 1

- [Task 1: Create an RDS database – optional \(p. 670\)](#)
- [Task 2: Launch an EC2 instance – optional \(p. 672\)](#)
- [Task 3: Automatically connect your EC2 instance to your RDS database \(p. 674\)](#)
- [Task 4: Verify the connection configuration \(p. 676\)](#)

Task 1: Create an RDS database – optional

Note

Creating a Amazon RDS database is not the focus of this tutorial. If you already have an RDS database and would like to use it in this tutorial, you can skip this task.

Task objective

The objective of this task is to create an RDS database so that you can complete Task 3 where you configure the connection between your EC2 instance and your RDS database. If you have an RDS database that you can use, you can skip this task.

Important

If you use an existing RDS database, make sure that it is in the same VPC as your EC2 instance so that you can use the automatic connection feature.

Steps to create an RDS database

Use the following steps to create an RDS database.

To view an animation of these steps, see [View an animation: Create an RDS database \(p. 672\)](#).

RDS database configuration

The steps in this task configure the RDS database as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: **tutorial-database-1**
- DB instance class: db.t3.micro

Important

In a production environment, you should configure your database to meet your specific needs.

To create a MySQL RDS database

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. From the Region selector (at top right), choose an AWS Region. The database and the EC2 instance must be in the same Region in order to use the automatic connection feature in the EC2 console.
3. On the dashboard, choose **Create database**.
4. Under **Choose a database creation method**, check that **Standard create** is selected. If you choose **Easy create**, the VPC selector is not available. You must ensure that your database is in the same VPC as your EC2 instance in order to use the automatic connection feature in the EC2 console.
5. Under **Engine options, for Engine type**, choose **MySQL**.
6. Under **Templates**, choose a sample template to meet your needs. For this tutorial, choose **Free tier** to create a database at no cost. However, note that the free tier is only available if your account is less than 12 months old. Other restrictions apply. You can read more by choosing the **Info** link in the **Free tier** box.
7. Under **Settings**, do the following:
 - a. For **DB instance identifier**, enter a name for the database. For this tutorial, enter **tutorial-database-1**.
 - b. For **Master username**, leave the default name, which is **admin**.
 - c. For **Master password**, enter a password that you can remember for this tutorial, and then, for **Confirm password**, enter the password again.
8. Under **Instance configuration**, for **DB instance class**, leave the default, which is **db.t3.micro**. If your account is less than 12 months, you can use this database class for free. Other restrictions apply. For more information, see [AWS Free Tier](#).
9. Under **Connectivity**, for **Compute resource**, choose **Don't connect to an EC2 compute resource** because you'll connect the EC2 instance and the RDS database later in Task 3.

(Later, in Option 2 of this tutorial, you'll try out the automatic connection feature in the RDS console by choosing **Connect to an EC2 compute resource**.)
10. For **Virtual private cloud (VPC)**, choose a VPC. The VPC must have a DB subnet group. To use the automatic connection feature, your EC2 instance and RDS database must be in the same VPC.
11. Keep all the default values for the other fields on this page.
12. Choose **Create database**.

On the **Databases** screen, the **Status** of the new database is **Creating** until the database is ready to use. When the status changes to **Available**, you can connect to the database. Depending on the

database class and the amount of storage, it can take up to 20 minutes before the new database is available.

View an animation: Create an RDS database

The screenshot shows the Amazon RDS Dashboard. On the left, there's a sidebar with links like Dashboard, Databases, Performance insights, Snapshots, Automated backups, Reserved instances, Proxies, Subnet groups, Parameter groups, Option groups, Custom engine versions, Events, Event subscriptions, and Certificate update. The main area has a callout box at the top right with the text: "Try the new Amazon RDS Multi-AZ deployment option for MySQL and PostgreSQL. For your Amazon RDS for MySQL and PostgreSQL workloads, improve transactional commit latencies instances by deploying the Multi-AZ DB cluster. Learn more". It includes a "Create database" button and a link to restore from a snapshot. Below this, there's a "Resources" section showing usage in the EU (Stockholm) region: DB Instances (3/40), DB Clusters (1/40), Reserved Instances (0/40), Snapshots (1), and various automated metrics. To the right, there are sections for Parameter groups (2), Option groups (1), Subnet groups (1/50), Supported platforms VPC, and Default network vpc-78678c. At the bottom, there's a "Create database" section with a note about the service making it easy to set up, operate, and scale a relational database.

You're now ready for [Task 2: Launch an EC2 instance – optional \(p. 672\)](#).

Task 2: Launch an EC2 instance – optional

Note

Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.

Task objective

The objective of this task is to launch an EC2 instance so that you can complete Task 3 where you configure the connection between your EC2 instance and your Amazon RDS database. If you have an EC2 instance that you can use, you can skip this task.

Important

If you use an existing EC2 instance, make sure that it is in the same VPC as your RDS database so that you can use the automatic connection feature.

Steps to launch an EC2 instance

Use the following steps to launch an EC2 instance for this tutorial.

To view an animation of these steps, see [View an animation: Launch an EC2 instance \(p. 674\)](#).

EC2 instance configuration

The steps in this task configure the EC2 instance as follows:

- Instance name: **tutorial-instance-1**
- AMI: Amazon Linux 2
- Instance type: t2.micro
- Auto-assign public IP: Enabled
- Security group with the following three rules:
 - Allow SSH from your IP address
 - Allow HTTPS traffic from anywhere
 - Allow HTTP traffic from anywhere

Important

In a production environment, you should configure your instance to meet your specific needs.

To launch an EC2 instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. From the Region selector (at top right), choose an AWS Region. The instance and the RDS database must be in the same Region in order to use the automatic connection feature in the EC2 console.
3. On the **EC2 Dashboard**, choose **Launch instance**.
4. Under **Name and tags**, for **Name**, enter a name to identify your instance. For this tutorial, name the instance **tutorial-instance-1**. While the instance name is not mandatory, when you select your instance in the EC2 console, the name will help you easily identify it.
5. Under **Application and OS Images**, choose an AMI that meets your web server needs. This tutorial uses **Amazon Linux 2**.
6. Under **Instance type**, for **Instance type**, select an instance type that meets your web server needs. This tutorial uses **t2.micro**.

Note

You can use Amazon EC2 under the [Free tier](#) provided your AWS account is less than 12 months old and you choose a t2.micro instance type (or t3.micro in Regions where t2.micro is not available).

7. Under **Key pair (login)**, for **Key pair name**, choose your key pair.
8. Under **Network settings**, do the following:
 - a. For **Network** and **Subnet**, if you haven't made changes to your default VPC or subnets, you can keep the default settings.

If you have made changes to your default VPC or subnets, check the following:

- i. The instance must be in the same VPC as the RDS database to use the automatic connection feature. By default you have only one VPC.
- ii. The VPC that you're launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.
- iii. To ensure that your instance receives a public IP address, for **Auto-assign public IP**, check that **Enable** is selected. If **Disable** is selected, choose **Edit** (to the right of **Network Settings**), and then, for **Auto-assign public IP**, choose **Enable**.

- b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer's public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

To make sure that only your IP address can connect to your instance, under **Firewall (security groups)**, from the drop-down list next to the **Allow SSH traffic from** check box, choose **My IP**.

- c. To allow traffic from the internet to your instance, select the following check boxes:

- **Allow HTTPs traffic from the internet**
- **Allow HTTP traffic from the internet**

9. In the **Summary** panel, review your instance configuration and then choose **Launch instance**.

10. Keep the confirmation page open. You'll need it for the next task when you automatically connect your instance to your database.

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 2114\)](#).

For more information about launching an instance, see [Launch an instance using the new launch instance wizard \(p. 552\)](#).

View an animation: Launch an EC2 instance

The screenshot shows the AWS EC2 Dashboard. On the left, a sidebar lists navigation options: New EC2 Experience (selected), EC2 Global View, Events, Tags, Limits, Instances (selected), Instances (New), Instance Types, Launch Templates, Spot Requests, Savings Plans, Reserved Instances (New), Dedicated Hosts, Capacity Reservations, Images (AMIs New, AMI Catalog), Elastic Block Store (Volumes, Snapshots, Lifecycle Manager), and Network & Security (Security Groups). The main content area has three main sections: Resources, Launch instance, and Service health. The Resources section displays metrics for Instances (running: 2), Dedicated Hosts (0), Elastic IPs (0), Instances (2), Key pairs (1), Load balancers (0), Placement groups (0), Security groups (10), and Volumes (3). The Launch instance section contains a 'Launch instance' button and a note: 'Note: Your Instances will launch in the Europe (Stockholm) Region'. The Service health section shows the Region as Europe (Stockholm) and the Status as 'This service is operating normally'. The Zones section lists Zone names (eu-north-1a, eu-north-1b, eu-north-1c) and Zone IDs (eun1-az1, eun1-az2, eun1-az3).

You're now ready for [Task 3: Automatically connect your EC2 instance to your RDS database \(p. 674\)](#).

Task 3: Automatically connect your EC2 instance to your RDS database

Task objective

The objective of this task is to use the automatic connection feature in the EC2 console to automatically configure the connection between your EC2 instance and your RDS database.

Steps to connect your EC2 instance and RDS database

Use the following steps to connect your EC2 instance and RDS database using the automatic feature in the EC2 console.

To view an animation of these steps, see [View an animation: Automatically connect a newly-launched EC2 instance to an RDS database \(p. 675\)](#).

To automatically connect an EC2 instance to an RDS database using the EC2 console

1. On the instance launch confirmation page (it should be open from the previous task), choose **Connect an RDS database**.

If you closed the confirmation page, follow these steps:

- a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
- b. In the navigation pane, choose **Instances**.
- c. Select the EC2 instance that you just created, and then choose **Actions, Networking, Connect RDS database**.

If **Connect RDS database** is not available, check that the EC2 instance is in the **Running** state.

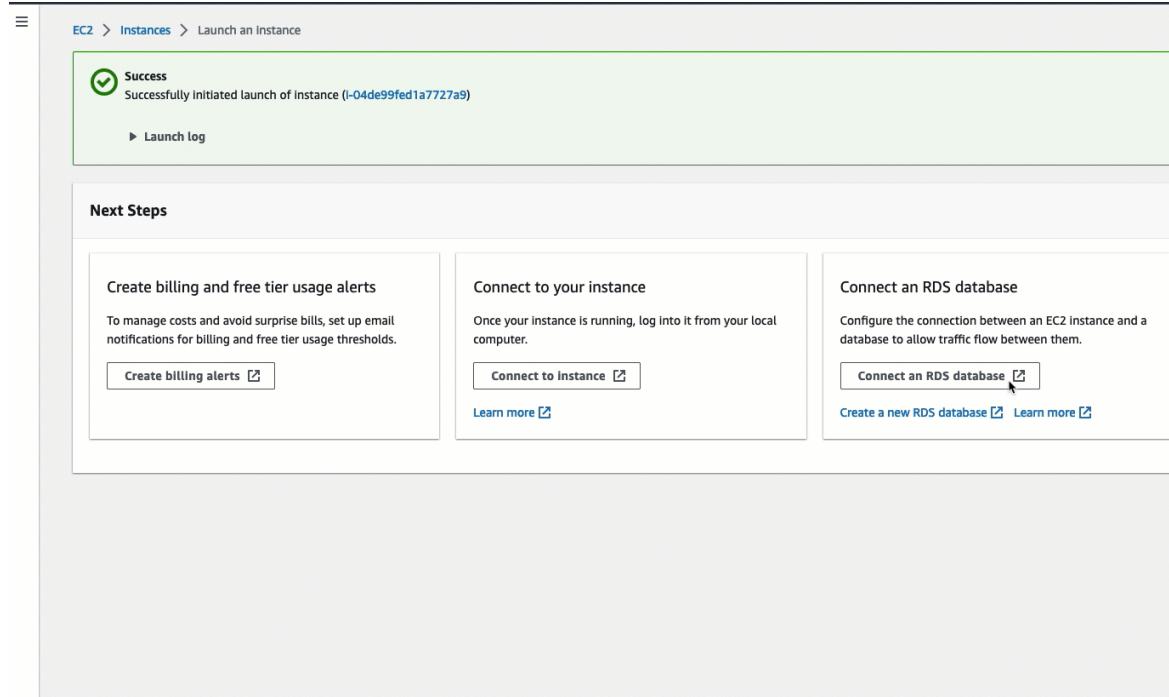

2. For **Database role**, choose **Instance**. *Instance* in this case refers to the database instance.
3. For **RDS database**, choose the RDS database that you created in Task 1.

Note

The EC2 instance and the RDS database must be in the same VPC in order to connect to each other.

4. Choose **Connect**.

[View an animation: Automatically connect a newly-launched EC2 instance to an RDS database](#)

You're now ready for [Task 4: Verify the connection configuration \(p. 676\)](#).

Task 4: Verify the connection configuration

Task objective

The objective of this task is to verify that the two security groups were created and assigned to the instance and database.

When you use the automatic connection feature in the EC2 console to configure the connectivity, the security groups are automatically created and assigned to the instance and database, as follows:

- Security group **rds-ec2-x** is created and added to the RDS database. It has one inbound rule that references the **ec2-rds-x** security group as its source. This allows traffic from the EC2 instance with the **ec2-rds-x** security group to reach the RDS database.
- Security group **ec2-rds-x** is created and added to the EC2 instance. It has one outbound rule that references the **rds-ec2-x** security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the **rds-ec2-x** security group.

Steps to verify the connection configuration

Use the following steps to verify the connection configuration.

To view an animation of these steps, see [View an animation: Verify the connection configuration \(p. 677\)](#).

To verify the connection configuration using the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation page, choose **Databases**.
3. Choose the RDS database that you created for this tutorial.
4. On the **Connectivity & security** tab, under **Security, VPC security groups**, verify that a security group called **rds-ec2-x** is displayed.
5. Choose the **rds-ec2-x** security group. The **Security Groups** screen in the EC2 console opens.
6. Choose the **rds-ec2-x** security group to open it.
7. Choose the **Inbound rules** tab.
8. Verify that the following security group rule exists, as follows:
 - Type: **MySQL/Aurora**
 - Port range: **3306**
 - Source: **sg-0987654321example / ec2-rds-x** – This is the security group that is assigned to the EC2 instance that you verified in the preceding steps.
 - Description: **Rule to allow connections from EC2 instances with sg-1234567890example attached**
9. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
10. In the navigation pane, choose **Instances**.
11. Choose the EC2 instance that you selected to connect to the RDS database in the previous task, and choose the **Security** tab.
12. Under **Security details, Security groups**, verify that a security group called **ec2-rds-x** is in the list. **x** is a number.
13. Choose the **ec2-rds-x** security group to open it.
14. Choose the **Outbound rules** tab.
15. Verify that the following security group rule exists, as follows:
 - Type: **MySQL/Aurora**

- Port range: **3306**
- Destination: **sg-1234567890example / rds-ec2-x**
- Description: **Rule to allow connections to database-tutorial from any instances this security group is attached to**

By verifying that these security groups and security group rules exist and that they are assigned to the RDS database and EC2 instance as described in this procedure, you can verify that the connection was automatically configured by using the automatic connection feature.

[View an animation: Verify the connection configuration](#)

The screenshot shows the AWS Console Home page. At the top, there's a header with "Console Home" and "Info" buttons, a "Reset to default layout" button, and an orange "+ Add widgets" button. Below the header is a "Recently visited" section with a list of services: RDS, EC2 (which is highlighted with a cursor icon), IAM, VPC, Support, AWS FIS, EFS, Key Management Service, S3, AWS Marketplace Subscriptions, CloudFormation, and Directory Service. There's also a "View all services" link. Below this is a "Welcome to AWS" section with links to "Getting started with AWS" (which includes a rocket icon) and "Training and certification" (which includes a graduation cap icon). To the right is an "AWS Health" section showing "Open issues" (0, past 7 days), "Scheduled changes" (0, upcoming and past 7 days), and "Other notifications" (0, past 7 days).

You have completed Option 1 of this tutorial. You can now either complete Option 2, which teaches you how to use the RDS console to automatically connect an EC2 instance to an RDS database, or you can complete Option 3, which teaches you how to manually configure the security groups that were automatically created in Option 1.

[Option 2: Automatically connect your EC2 instance to your RDS database using the RDS console](#)

Objective

The objective of Option 2 is to explore the automatic connect feature in the RDS console that automatically configures the connection between your EC2 instance and RDS database to allow traffic from the EC2 instance to the RDS database. In Option 3, you'll learn how to manually configure the connection.

Before you begin

You'll need the following to complete this tutorial:

- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 1 to create a new instance.
- Permissions to call the following operations:
 - ec2:AssociateRouteTable
 - ec2:AuthorizeSecurityGroupEgress
 - ec2>CreateRouteTable
 - ec2>CreateSecurityGroup
 - ec2>CreateSubnet
 - ec2:DescribeInstances
 - ec2:DescribeNetworkInterfaces
 - ec2:DescribeRouteTables
 - ec2:DescribeSecurityGroups
 - ec2:DescribeSubnets
 - ec2:ModifyNetworkInterfaceAttribute
 - ec2:RevokeSecurityGroupEgress

Tasks to complete Option 2

- [Task 1: Launch an EC2 instance – optional \(p. 678\)](#)
- [Task 2: Create an RDS database and automatically connect it to your EC2 instance \(p. 680\)](#)
- [Task 3: Verify the connection configuration \(p. 682\)](#)

Task 1: Launch an EC2 instance – *optional*

Note

Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.

Task objective

The objective of this task is to launch an EC2 instance so that you can complete Task 2 where you configure the connection between your EC2 instance and your Amazon RDS database. If you have an EC2 instance that you can use, you can skip this task.

Steps to launch an EC2 instance

Use the following steps to launch an EC2 instance for this tutorial.

To view an animation of these steps, see [View an animation: Launch an EC2 instance \(p. 680\)](#).

EC2 instance configuration

The steps in this task configure the EC2 instance as follows:

- Instance name: **tutorial-instance-2**
- AMI: Amazon Linux 2
- Instance type: t2.micro
- Auto-assign public IP: Enabled
- Security group with the following three rules:
 - Allow SSH from your IP address
 - Allow HTTPS traffic from anywhere

- Allow HTTP traffic from anywhere

Important

In a production environment, you should configure your instance to meet your specific needs.

To launch an EC2 instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. On the **EC2 Dashboard**, choose **Launch instance**.
3. Under **Name and tags**, for **Name**, enter a name to identify your instance. For this tutorial, name the instance **tutorial-instance-2**. While the instance name is not mandatory, when you select your instance in the RDS console, the name will help you easily identify it.
4. Under **Application and OS Images**, choose an AMI that meets your web server needs. This tutorial uses **Amazon Linux**.
5. Under **Instance type**, for **Instance type**, select an instance type that meets your web server needs. This tutorial uses **t2.micro**.

Note

You can use Amazon EC2 under the [Free tier](#) provided your AWS account is less than 12 months old and you choose a **t2.micro** instance type (or **t3.micro** in Regions where **t2.micro** is not available).

6. Under **Key pair (login)**, for **Key pair name**, choose your key pair.
7. Under **Network settings**, do the following:

- a. For **Network** and **Subnet**, if you haven't made changes to your default VPC or subnets, you can keep the default settings.

If you have made changes to your default VPC or subnets, check the following:

- i. The instance must be in the same VPC as the RDS database to use the automatic connection configuration. By default you have only one VPC.
 - ii. The VPC that you're launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.
 - iii. To ensure that your instance receives a public IP address, for **Auto-assign public IP**, check that **Enable** is selected. If **Disable** is selected, choose **Edit** (to the right of **Network Settings**), and then, for **Auto-assign public IP**, choose **Enable**.
- b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer's public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

To make sure that only your IP address can connect to your instance, under **Firewall (security groups)**, from the drop-down list next to the **Allow SSH traffic from** check box, choose **My IP**.

- c. To allow traffic from the internet to your instance, select the following check boxes:
 - **Allow HTTPs traffic from the internet**
 - **Allow HTTP traffic from the internet**

8. In the **Summary** panel, review your instance configuration and then choose **Launch instance**.
9. Choose **View all instances** to close the confirmation page and return to the console. Your instance will first be in a pending state, and will then go into the running state.

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 2114\)](#).

For more information about launching an instance, see [Launch an instance using the new launch instance wizard \(p. 552\)](#).

View an animation: Launch an EC2 instance

The screenshot shows the Amazon EC2 Dashboard. On the left, a sidebar lists various services: EC2 Dashboard, EC2 Global View, Events, Tags, Limits, Instances (with sub-options like Instances, Instance Types, Launch Templates, Spot Requests, Savings Plans, Reserved Instances, Dedicated Hosts, Capacity Reservations), Images (AMIs, AMI Catalog), Elastic Block Store (Volumes, Snapshots, Lifecycle Manager), and Network & Security (Security Groups). The main area is titled 'Resources' and displays a summary of EC2 resources in the Europe (Stockholm) Region. It includes tables for Instances (running: 2), Dedicated Hosts (0), Elastic IPs (0), Instances (2), Key pairs (1), Load balancers (0), Placement groups (0), Security groups (10), and Volumes (3). Below this is a note about AWS re:Invent videos. To the right, there's a 'Service health' section showing the region is operating normally and a 'Zones' section listing three availability zones: eu-north-1a, eu-north-1b, and eu-north-1c, each associated with zone ID eun1-az1, eun1-az2, and eun1-az3 respectively. In the center, there's a 'Launch instance' section with a prominent orange 'Launch Instance' button.

You're now ready for [Task 2: Create an RDS database and automatically connect it to your EC2 instance \(p. 680\)](#).

Task 2: Create an RDS database and automatically connect it to your EC2 instance

Task objective

The objective of this task is to create an RDS database and use the automatic connection feature in the RDS console to automatically configure the connection between your EC2 instance and your RDS database.

Steps to create an RDS database

Use the following steps to create an RDS database and connect it to your EC2 instance using the automatic feature in the RDS console.

To view an animation of these steps, see [View an animation: Create an RDS database and automatically connect it to an EC2 instance \(p. 682\)](#).

DB instance configuration

The steps in this task configure the DB instance as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: **tutorial-database**

- DB instance class: db.t3.micro

Important

In a production environment, you should configure your instance to meet your specific needs.

To create an RDS database and automatically connect it to an EC2 instance

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. From the Region selector (at top right), choose the AWS Region in which you created the EC2 instance. The EC2 instance and the RDS database must be in the same Region.
3. On the dashboard, choose **Create database**.
4. Under **Choose a database creation method**, check that **Standard create** is selected. If you choose **Easy create**, the automatic connection feature is not available.
5. Under **Engine options**, for **Engine type**, choose **MySQL**.
6. Under **Templates**, choose a sample template to meet your needs. For this tutorial, choose **Free tier** to create an RDS database at no cost. However, note that the free tier is only available if your account is less than 12 months old. Other restrictions apply. You can read more by choosing the **Info** link in the **Free tier** box.
7. Under **Settings**, do the following:
 - a. For **DB instance identifier**, enter a name for the database. For this tutorial, enter **tutorial-database**.
 - b. For **Master username**, leave the default name, which is **admin**.
 - c. For **Master password**, enter a password that you can remember for this tutorial, and then, for **Confirm password**, enter the password again.
8. Under **Instance configuration**, for **DB instance class**, leave the default, which is **db.t3.micro**. If your account is less than 12 months, you can use this instance for free. Other restrictions apply. For more information, see [AWS Free Tier](#).
9. Under **Connectivity**, for **Compute resource**, choose **Connect to an EC2 compute resource**. This is the automatic connection feature in the RDS console .
10. For **EC2 instance**, choose the EC2 instance that you want to connect to. For the purposes of this tutorial, you can either choose the instance that you created in the previous task, which you named **tutorial-instance**, or choose another existing instance. If you don't see your instance in the list, choose the refresh icon to the right of **Connectivity**.

When you use the automatic connection feature, a security group is added to this EC2 instance, and another security group is added to the RDS database. The security groups are automatically configured to allow traffic between the EC2 instance and the RDS database. In the next task, you'll verify that the security groups were created and assigned to the EC2 instance and RDS database.

11. Choose **Create database**.

On the **Databases** screen, the **Status** of the new database is **Creating** until the database is ready to use. When the status changes to **Available**, you can connect to the database. Depending on the database class and the amount of storage, it can take up to 20 minutes before the new database is available.

To learn more, see [Configure automatic network connectivity with an EC2 instance](#) in the *Amazon RDS User Guide*.

View an animation: Create an RDS database and automatically connect it to an EC2 instance

The screenshot shows the Amazon RDS console interface. On the left, there's a sidebar with navigation links: Dashboard, Databases, Performance insights, Snapshots, Automated backups, Reserved instances, Proxies, Subnet groups, Parameter groups, Option groups, Custom engine versions, Events, Event subscriptions, and Certificate update. The main area has a large blue callout box with an info icon that says "Try the new Amazon RDS Multi-AZ deployment option for MySQL and PostgreSQL". It also says "For your Amazon RDS for MySQL and PostgreSQL workloads, improve transactional instances by deploying the Multi-AZ DB cluster" and has a "Learn more" link. Below this is a "Create database" button, which is highlighted with a mouse cursor. Underneath the button, it says "Or, Restore Multi-AZ DB Cluster from Snapshot". To the right of the callout, there's a "Resources" section showing usage statistics for the EU (Stockholm) region: DB Instances (5/40), DB Clusters (1/40), Reserved Instances (0/40), and Snapshots (2). Below these are sections for Manual and Automated resources, each with DB Cluster (0/100) and DB Instance (0/100) counts. At the bottom of the main content area, there's a "Create database" button and a note: "Amazon Relational Database Service (RDS) makes it easy to set up, operate, and scale a relational database in the cloud".

You're now ready for [Task 3: Verify the connection configuration \(p. 682\)](#).

Task 3: Verify the connection configuration

Task objective

The objective of this task is to verify that the two security groups were created and assigned to the instance and the database.

When you use the automatic connection feature in the RDS console to configure the connectivity, the security groups are automatically created and assigned to the instance and database, as follows:

- Security group **rds-ec2-x** is created and added to the RDS database. It has one inbound rule that references the **ec2-rds-x** security group as its source. This allows traffic from the EC2 instance with the **ec2-rds-x** security group to reach the RDS database.
- Security group **ec2-rds-x** is created and added to the EC2 instance. It has one outbound rule that references the **rds-ec2-x** security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the **rds-ec2-x** security group.

Steps to verify the connection configuration

Use the following steps to verify the connection configuration.

To view an animation of these steps, see [View an animation: Verify the connection configuration \(p. 684\)](#).

To verify the connection configuration using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Choose the EC2 instance that you selected to connect to the RDS database in the previous task, and choose the **Security** tab.
4. Under **Security details, Security groups**, verify that a security group called **ec2-rds-x** is in the list. *x* is a number.
5. Choose the **ec2-rds-x** security group to open it.
6. Choose the **Outbound rules** tab.
7. Verify that the following security group rule exists, as follows:
 - Type: **MySQL/Aurora**
 - Port range: **3306**
 - Destination: **sg-1234567890example / rds-ec2-x**
 - Description: **Rule to allow connections to database-tutorial from any instances this security group is attached to**
8. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
9. In the navigation page, choose **Databases**.
10. Choose the RDS database that you created for this tutorial.
11. On the **Connectivity & security** tab, under **Security, VPC security groups**, verify that a security group called **rds-ec2-x** is displayed.
12. Choose the **rds-ec2-x** security group. The **Security Groups** screen in EC2 console opens.
13. Choose the **rds-ec2-x** security group open it.
14. Choose the **Inbound rules** tab.
15. Verify that the following security group rule exists, as follows:
 - Type: **MySQL/Aurora**
 - Port range: **3306**
 - Source: **sg-0987654321example / ec2-rds-x** – This is the security group that is assigned to the EC2 instance that you verified in the preceding steps.
 - Description: **Rule to allow connections from EC2 instances with sg-1234567890example attached**

By verifying that these security groups and security group rules exist and that they are assigned to the EC2 instance and RDS database as described in this procedure, you can verify that the connection was automatically configured by using the automatic connection feature.

[View an animation: Verify the connection configuration](#)

The screenshot shows the AWS Console Home page. At the top, there's a header with "Console Home" and "Info" buttons, "Reset to default layout", and a "+ Add widgets" button. Below the header is a "Recently visited" section with a list of services: RDS, EC2 (which is highlighted with a cursor icon), IAM, VPC, Support, AWS FIS, EFS, Key Management Service, S3, AWS Marketplace Subscriptions, CloudFormation, and Directory Service. Below this is a "View all services" link. To the right of the recently visited list are two widgets: "Welcome to AWS" and "AWS Health". The "Welcome to AWS" widget has sections for "Getting started with AWS" (with a rocket icon) and "Training and certification" (with a graduation cap icon). The "AWS Health" widget shows "Open issues: 0 (Past 7 days)", "Scheduled changes: 0 (Upcoming and past 7 days)", and "Other notifications: 0 (Past 7 days)".

You have completed Option 2 of this tutorial. You can now either complete Option 3, which teaches you how to manually configure the security groups that were automatically created in Option 2.

Option 3: Manually connect your EC2 instance to your RDS database by mimicking the automatic connection feature

Objective

The objective of Option 3 is to learn how to manually configure the connection between an EC2 instance and an RDS database by manually reproducing the configuration of the automatic connection feature.

Before you begin

You'll need the following to complete this tutorial:

- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 1 to create a new instance.
- An RDS database that is in the same VPC as the EC2 instance. You can either use an existing RDS database or follow the steps in Task 2 to create a new database.
- Permissions to call the following operations. If you have completed Option 1 of this tutorial, you already have these permissions.
 - `ec2:AssociateRouteTable`
 - `ec2:AuthorizeSecurityGroupEgress`
 - `ec2>CreateRouteTable`
 - `ec2:CreateSecurityGroup`
 - `ec2:CreateSubnet`

- ec2:DescribeInstances
- ec2:DescribeNetworkInterfaces
- ec2:DescribeRouteTables
- ec2:DescribeSecurityGroups
- ec2:DescribeSubnets
- ec2:ModifyNetworkInterfaceAttribute
- ec2:RevokeSecurityGroupEgress

Tasks to complete Option 3

- [Task 1: Launch an EC2 instance – optional \(p. 685\)](#)
- [Task 2: Create an RDS database – optional \(p. 687\)](#)
- [Task 3: Manually connect your EC2 instance to your RDS database by creating security groups and assigning them to the instances \(p. 689\)](#)

Task 1: Launch an EC2 instance – optional

Note

Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.

Task objective

The objective of this task is to launch an EC2 instance so that you can complete Task 3 where you configure the connection between your EC2 instance and your Amazon RDS database.

Steps to launch an EC2 instance

Use the following steps to launch an EC2 instance for this tutorial.

To view an animation of these steps, see [View an animation: Launch an EC2 instance \(p. 687\)](#).

EC2 instance configuration

The steps in this task configure the EC2 instance as follows:

- Instance name: **tutorial-instance**
- AMI: Amazon Linux 2
- Instance type: t2.micro
- Auto-assign public IP: Enabled
- Security group with the following three rules:
 - Allow SSH from your IP address
 - Allow HTTPS traffic from anywhere
 - Allow HTTP traffic from anywhere

Important

In a production environment, you should configure your instance to meet your specific needs.

To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.

2. On the **EC2 Dashboard**, choose **Launch instance**.
3. Under **Name and tags**, for **Name**, enter a name to identify your instance. For this tutorial, name the instance **tutorial-instance-manual-1**. While the instance name is not mandatory, the name will help you easily identify it.
4. Under **Application and OS Images**, choose an AMI that meets your web server needs. This tutorial uses **Amazon Linux**.
5. Under **Instance type**, for **Instance type**, select an instance type that meets your web server needs. This tutorial uses **t2.micro**.

Note

You can use Amazon EC2 under the [Free tier](#) provided your AWS account is less than 12 months old and you choose a **t2.micro** instance type (or **t3.micro** in Regions where **t2.micro** is not available).

6. Under **Key pair (login)**, for **Key pair name**, choose your key pair.
 7. Under **Network settings**, do the following:
 - a. For **Network and Subnet**, if you haven't made changes to your default VPC or subnets, you can keep the default settings.
- If you have made changes to your default VPC or subnets, check the following:
- i. The instance must be in the same VPC as the RDS database. By default you have only one VPC.
 - ii. The VPC that you're launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.
 - iii. To ensure that your instance receives a public IP address, for **Auto-assign public IP**, check that **Enable** is selected. If **Disable** is selected, choose **Edit** (to the right of **Network Settings**), and then, for **Auto-assign public IP**, choose **Enable**.
- b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer's public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

To make sure that only your IP address can connect to your instance, under **Firewall (security groups)**, from the drop-down list next to the **Allow SSH traffic from** check box, choose **My IP**.

- c. To allow traffic from the internet to your instance, select the following check boxes:
 - **Allow HTTPPs traffic from the internet**
 - **Allow HTTP traffic from the internet**

8. In the **Summary** panel, review your instance configuration and then choose **Launch instance**.
9. Choose **View all instances** to close the confirmation page and return to the console. Your instance will first be in a pending state, and will then go into the running state.

If the instance fails to launch or the state immediately goes to terminated instead of running, see [Troubleshoot instance launch issues \(p. 2114\)](#).

For more information about launching an instance, see [Launch an instance using the new launch instance wizard \(p. 552\)](#).

View an animation: Launch an EC2 instance

The screenshot shows the Amazon EC2 Dashboard for the Europe (Stockholm) Region. On the left, a sidebar lists navigation options: New EC2 Experience, EC2 Dashboard, Events, Tags, Limits, Instances (selected), Instances, Instance Types, Launch Templates, Spot Requests, Savings Plans, Reserved Instances, Dedicated Hosts, Capacity Reservations, Images (AMIs, AMI Catalog), Elastic Block Store (Volumes, Snapshots, Lifecycle Manager), and Network & Security (Security Groups). The main area displays 'Resources' with counts for Instances (running: 2), Dedicated Hosts (0), Elastic IPs (0), Instances (2), Key pairs (1), Load balancers (0), Placement groups (0), Security groups (10), and Volumes (3). A callout box says 'Learn more about the latest in AWS Compute from AWS re:Invent by viewing the [EC2 Videos](#)'. Below this is the 'Launch instance' section, which includes a 'Launch Instance' button and a 'Migrate a server' link. It notes that instances will launch in the Europe (Stockholm) Region. To the right is the 'Service health' section, showing the region as Europe (Stockholm) and the status as 'This service is operating normally'. The 'Zones' section lists three availability zones: eu-north-1a (Zone ID: eun1-az1), eu-north-1b (Zone ID: eun1-az2), and eu-north-1c (Zone ID: eun1-az3).

You are now ready for [Task 2: Create an RDS database – optional \(p. 687\)](#).

Task 2: Create an RDS database – optional

Note

Creating an RDS database is not the focus of this part of the tutorial. If you already have an RDS database and would like to use it for this tutorial, you can skip this task.

Task objective

The objective of this task is to create an RDS database. You'll use this instance in Task 3 when you connect it to your EC2 instance.

Steps to create an RDS database

Use the following steps to create an RDS database for Option 3 of this tutorial.

To view an animation of these steps, see [View an animation: Create a DB instance \(p. 689\)](#).

RDS database configuration

The steps in this task configure the RDS database as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: **tutorial-database-manual**
- DB instance class: db.t3.micro

Important

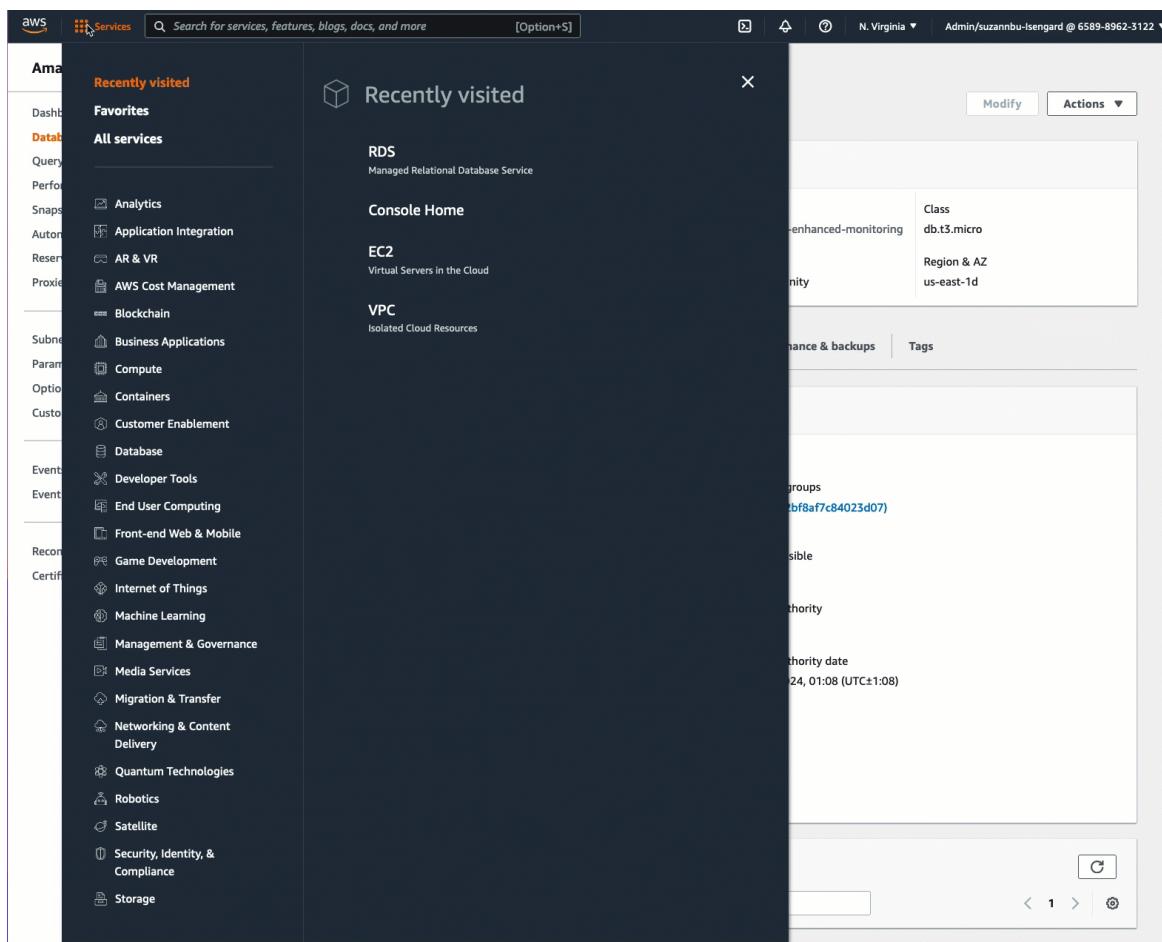

In a production environment, you should configure your instance to meet your specific needs.

To create a MySQL DB instance

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. From the Region selector (at top right), choose the AWS Region in which you created the EC2 instance. The EC2 instance and the DB instance must be in the same Region.
3. On the dashboard, choose **Create database**.
4. Under **Choose a database creation method**, choose **Easy create**. When you choose this option, the automatic connection feature to automatically configure the connection is not available.
5. Under **Engine options**, for **Engine type**, choose **MySQL**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier** enter a name for the RDS database. For this tutorial, enter **tutorial-database-manual**.
8. For **Master username**, leave the default name, which is **admin**.
9. For **Master password**, enter a password that you can remember for this tutorial, and then, for **Confirm password**, enter the password again.
10. Choose **Create database**.

On the **Databases** screen, the **Status** of the new DB instance is **Creating** until the DB instance is ready to use. When the status changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

View an animation: Create a DB instance

You are now ready for [Task 3: Manually connect your EC2 instance to your RDS database by creating security groups and assigning them to the instances \(p. 689\)](#).

Task 3: Manually connect your EC2 instance to your RDS database by creating security groups and assigning them to the instances

Task objective

The objective of this task is to reproduce the connection configuration of the automatic connection feature by performing the following manually: You create two new security groups, and then add a security group each to the EC2 instance and the RDS database.

Steps to create new security groups and add them to the instances

Use the following steps to connect an EC2 instance to your RDS database by creating two new security groups. You then add a security group each to the EC2 instance and the RDS database.

To create two new security groups and assign one each to the EC2 instance and RDS database

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. First create the security group to add to the EC2 instance, as follows:
 - a. In the navigation pane, choose **Security Groups**.
 - b. Choose **Create security group**.

- c. For **Security group name**, enter a descriptive name for the security group. For this tutorial, enter **ec2-rds-manual-configuration**.
 - d. For **Description**, enter a brief description. For this tutorial, enter **EC2 instance security group to allow EC2 instance to securely connect to RDS database**.
 - e. Choose **Create security group**. You'll come back to this security group to add an outbound rule after you've created the RDS database security group.
3. Now, create the security group to add to the RDS database, as follows:
- a. In the navigation pane, choose **Security Groups**.
 - b. Choose **Create security group**.
 - c. For **Security group name**, enter a descriptive name for the security group. For this tutorial, enter **rds-ec2-manual-configuration**.
 - d. For **Description**, enter a brief description. For this tutorial, enter **RDS database security group to allow EC2 instance to securely connect to RDS database**.
 - e. Under **Inbound rules**, choose **Add rule**, and do the following:
 - i. For **Type**, choose **MySQL/Aurora**.
 - ii. For **Source**, choose the EC2 instance security group **ec2-rds-manual-configuration** that you created in Step 2 of this procedure.
 - f. Choose **Create security group**.
4. Edit the EC2 instance security group to add an outbound rule, as follows:
- a. In the navigation pane, choose **Security Groups**.
 - b. Select the EC2 instance security group (you named it **ec2-rds-manual-configuration**), and choose the **Outbound rules** tab.
 - c. Choose **Edit outbound rules**.
 - d. Choose **Add rule**, and do the following:
 - i. For **Type**, choose **MySQL/Aurora**.
 - ii. For **Source**, choose the RDS database security group **rds-ec2-manual-configuration** that you created in Step 3 of this procedure.
 - iii. Choose **Save rules**.
5. Add the EC2 instance security group to the EC2 instance as follows:
- a. In the navigation pane, choose **Instances**.
 - b. Select your EC2 instance, and choose **Actions, Security, Change security groups**.
 - c. Under **Associated security groups**, choose the **Select security groups** field, choose **ec2-rds-manual-configuration** that you created earlier, and then choose **Add security group**.
 - d. Choose **Save**.
6. Add the RDS database security group to the RDS database as follows:
- a. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
 - b. In the navigation pane, choose **Databases** and select your database.
 - c. Choose **Modify**.
 - d. Under **Connectivity**, for **Security group**, choose **rds-ec2-manual-configuration** that you created earlier, and then choose **Continue**.
 - e. Under **Scheduling of modifications**, choose **Apply immediately**.
 - f. Choose **Modify DB instance**.

You have now completed the manual steps that mimic the automatic steps that occur when you use the automatic connection feature.

You have completed Option 3 of this tutorial. If you've completed Options 1, 2, and 3, and you no longer need the resources that were created in this tutorial, you should delete them to prevent incurring unnecessary costs. For more information, see [Clean up \(p. 691\)](#).

Clean up

Now that you have completed the tutorial, it is good practice to clean up (delete) any resources you no longer want to use. Cleaning up AWS resources prevents your account from incurring any further charges.

Topics

- [Terminate your EC2 instance \(p. 691\)](#)
- [Delete your RDS database \(p. 691\)](#)

Terminate your EC2 instance

If you launched an EC2 instance specifically for this tutorial, you can terminate it to stop incurring any charges associated with it.

To terminate an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance that you created for this tutorial, and choose **Instance state, Terminate instance**.
4. Choose **Terminate** when prompted for confirmation.

Delete your RDS database

If you created an RDS database specifically for this tutorial, you can delete it to stop incurring any charges associated with it.

To delete an RDS database using the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Select the RDS database that you created for this tutorial, and choose **Actions, Delete**.
4. Enter **delete me** in the box, and then choose **Delete**.

Configure your Windows instance

A Windows instance is a virtual server running Windows Server in the cloud.

After you have successfully launched and logged into your instance, you can make changes to it so that it's configured to meet the needs of a specific application. The following are some common tasks to help you get started.

Contents

- [Configure a Windows instance using EC2Launch v2 \(p. 692\)](#)
- [Configure a Windows instance using EC2Launch \(p. 743\)](#)
- [Configure a Windows instance using the EC2Config service \(p. 753\)](#)

- [Paravirtual drivers for Windows instances \(p. 780\)](#)
- [AWS NVMe drivers for Windows instances \(p. 799\)](#)
- [Optimize CPU options \(p. 803\)](#)
- [Set the time for a Windows instance \(p. 839\)](#)
- [Set the password for a Windows instance \(p. 844\)](#)
- [Add Windows components using installation media \(p. 845\)](#)
- [Configure a secondary private IPv4 address for your Windows instance \(p. 849\)](#)
- [Run commands on your Windows instance at launch \(p. 853\)](#)
- [Instance metadata and user data \(p. 862\)](#)
- [Best practices and recommendations for SQL Server clustering in Amazon EC2 \(p. 926\)](#)
- [Install WSL on your Windows instance \(p. 926\)](#)

Configure a Windows instance using EC2Launch v2

All supported instances of Amazon EC2 running Windows Server 2022 include the EC2Launch v2 launch agent (EC2Launch.exe) by default. We also provide Windows Server 2016 and 2019 AMIs with EC2Launch v2 installed as the default launch agent. These AMIs are provided in addition to the Windows Server 2016 and 2019 AMIs that include EC2Launch v1. You can search for Windows AMIs that include EC2Launch v2 by default by entering the following prefix in your search from the **AMIs** page in the Amazon EC2 console: EC2LaunchV2-Windows_Server-*.

EC2Launch v2 performs tasks during instance startup and runs if an instance is stopped and later started, or restarted. EC2Launch v2 can also perform tasks on demand. Some of these tasks are automatically enabled, while others must be enabled manually. The EC2Launch v2 service supports all EC2Config and EC2Launch features.

This service uses a configuration file to control its operation. You can update the configuration file using either a graphical tool or by directly editing it as a single .yml file (agent-config.yml). The service binaries are located in the %ProgramFiles%\Amazon\EC2Launch directory.

EC2Launch v2 publishes Windows event logs to help you troubleshoot errors and set triggers. For more information, see [Windows event logs \(p. 734\)](#).

Supported operating systems

- Windows Server 2022
- Windows Server 2019 (Long-Term Servicing Channel and Semi-Annual Channel)
- Windows Server 2016
- Windows Server 2012 and 2012 R2

EC2Launch v2 section contents

- [EC2Launch v2 overview \(p. 693\)](#)
- [Install the latest version of EC2Launch v2 \(p. 697\)](#)
- [Migrate to EC2Launch v2 \(p. 700\)](#)
- [Stop, restart, delete, or uninstall EC2Launch v2 \(p. 701\)](#)
- [Subscribe to EC2Launch v2 service notifications \(p. 702\)](#)
- [EC2Launch v2 settings \(p. 703\)](#)
- [Troubleshoot EC2Launch v2 \(p. 730\)](#)
- [EC2Launch v2 version histories \(p. 739\)](#)

EC2Launch v2 overview

EC2Launch v2 is a service that performs tasks during instance startup and runs if an instance is stopped and later started, or restarted.

Note

To use EC2Launch with IMDSv2, the version must be 1.3.2002730 or later.

Overview topics

- [Compare Amazon EC2 launch services \(p. 693\)](#)
- [EC2Launch v2 concepts \(p. 694\)](#)
- [EC2Launch v2 tasks \(p. 695\)](#)
- [Telemetry \(p. 696\)](#)

Compare Amazon EC2 launch services

The following table shows the major functional differences between EC2Config, EC2Launch v1, and EC2Launch v2.

Feature	EC2Config	EC2Launch v1	EC2Launch v2
Run as	Windows Service	PowerShell Scripts	Windows Service
Supports	Windows 2012 Windows 2012 R2	Windows 2016 Windows 2019 (LTSC and SAC)	Windows 2012 Windows 2016 Windows 2019 (LTSC and SAC) Windows 2022
Configuration file	XML	XML	YAML
Set Administrator username	No	No	Yes
User data size	16 KB	16 KB	60 KB (compressed)
Local user data baked on AMI	No	No	Yes, configurable
Task configuration in user data	No	No	Yes
Configurable wallpaper	No	No	Yes
Customize task run order	No	No	Yes
Configurable tasks	15	9	20 at launch
Supports Windows Event Viewer	Yes	No	Yes

Feature	EC2Config	EC2Launch v1	EC2Launch v2
Number of Event Viewer event types	2	0	30

EC2Launch v2 concepts

The following concepts are useful to understand when considering EC2Launch v2.

Task

You can invoke a task to perform an action on an instance. You can configure tasks in the `agent-config.yml` file or through user data. For a list of available tasks for EC2Launch v2, see [EC2Launch v2 tasks \(p. 695\)](#). For task configuration schema and details, see [EC2Launch v2 task configuration \(p. 716\)](#).

Stage

A stage is a logical grouping of tasks that the EC2Launch v2 agent runs. Some tasks can run only in a specific stage. Others can run in multiple stages. When using `agent-config.yml`, you must specify a list of stages, and a list of tasks to run within each stage.

The service runs stages in the following order:

Stage 1: Boot

Stage 2: Network

Stage 3: PreReady

Windows is ready

After the PreReady stage completes, the service sends the `Windows is ready` message to the Amazon EC2 console.

Stage 4: PostReady

User data runs during the `PostReady` stage. Some script versions run before the `agent-config.yml` file `PostReady` stage, and some run after, as follows:

Before `agent-config.yml`

- YAML user data version 1.1
- XML user data

After `agent-config.yml`

- YAML user data version 1.0 (legacy version for backwards compatibility)

For example stages and tasks, see [Example: agent-config.yml \(p. 716\)](#).

When you use user data, you must specify a list of tasks for the launch agent to run. The stage is implied. For example tasks, see [Example: user data \(p. 718\)](#).

EC2Launch v2 runs the list of tasks in the order that you specify in `agent-config.yml` and in user data. Stages run sequentially. The next stage starts after the previous stage completes. Tasks also run sequentially.

Frequency

Task frequency determines when tasks should run, depending on the boot context. Most tasks have only one allowed frequency. You can specify a frequency for executeScript tasks.

You will see the following frequencies in the [EC2Launch v2 task configuration \(p. 716\)](#).

- Once – The task runs once, when the AMI has booted for the first time (finished Sysprep).
- Always – The task runs every time that the launch agent runs. The launch agent runs when:
 - an instance starts or restarts
 - the EC2Launch service runs
 - EC2Launch.exe run is invoked

agent-config

agent-config is a file that is located in the configuration folder for EC2Launch v2. It includes configuration for the boot, network, PreReady, and PostReady stages. This file is used to specify the instance configuration for tasks that should run when the AMI is either booted for the first time or for subsequent times.

By default, the EC2Launch v2 installation installs an agent-config file that includes recommended configurations that are used in standard Amazon Windows AMIs. You can update the configuration file to alter the default boot experience for your AMI that EC2Launch v2 specifies.

User data

User data is data that is configurable when you launch an instance. You can update user data to dynamically change how custom AMIs or quickstart AMIs are configured. EC2Launch v2 supports 60 kB user data input length. User data includes only the UserData stage, and therefore runs after the agent-config file. You can enter user data when you launch an instance using the launch instance wizard, or you can modify user data from the EC2 console. For more information about working with user data, see [Run commands on your Windows instance at launch \(p. 853\)](#).

EC2Launch v2 tasks

EC2Launch v2 can perform the following tasks at each boot:

- Set up new and optionally customized wallpaper that renders information about the instance.
- Set the attributes for the administrator account that is created on the local machine.
- Add DNS suffixes to the list of search suffixes. Only suffixes that do not already exist are added to the list.
- Set drive letters for any additional volumes and extend them to use available space.
- Write files to the disk, either from the internet or from the configuration. If the content is in the configuration, it can be base64 decoded or encoded. If the content is from the internet, it can be unzipped.
- Run scripts either from the internet or from the configuration. If the script is from the configuration, it can be base64 decoded. If the script is from the internet, it can be unzipped.
- Run a program with given arguments.
- Set the computer name.
- Send instance information to the Amazon EC2 console.
- Send the RDP certificate thumbprint to the Amazon EC2 console.
- Dynamically extend the operating system partition to include any unpartitioned space.
- Run user data. For more information about specifying user data, see [EC2Launch v2 task configuration \(p. 716\)](#).
- Set non-persistent static routes to reach the metadata service and AWS KMS servers.

- Set non-boot partitions to MBR or GPT.
- Start the Systems Manager service following Sysprep.
- Optimize ENA settings.
- Enable OpenSSH for later Windows versions.
- Enable Jumbo Frames.
- Set Sysprep to run with EC2Launch v2.
- Publish Windows event logs.

Telemetry

Telemetry is additional information that helps AWS to better understand your requirements, diagnose issues, and deliver features to improve your experience with AWS services.

EC2Launch v2 version 2.0.592 and later collect telemetry, such as usage metrics and errors. This data is collected from the Amazon EC2 instance on which EC2Launch v2 runs. This includes all Windows AMIs owned by AWS.

The following types of telemetry are collected by EC2Launch v2:

- **Usage information** — agent commands, install method, and scheduled run frequency.
- **Errors and diagnostic information** — agent installation and run error codes.

Examples of collected data:

```
2021/07/15 21:44:12Z: EC2LaunchTelemetry: IsAgentScheduledPerBoot=true
2021/07/15 21:44:12Z: EC2LaunchTelemetry: IsUserDataScheduledPerBoot=true
2021/07/15 21:44:12Z: EC2LaunchTelemetry: AgentCommandCode=1
2021/07/15 21:44:12Z: EC2LaunchTelemetry: AgentCommandErrorCode=5
2021/07/15 21:44:12Z: EC2LaunchTelemetry: AgentInstallCode=2
2021/07/15 21:44:12Z: EC2LaunchTelemetry: AgentInstallErrorCode=0
```

Telemetry is enabled by default. You can disable telemetry collection at any time. If telemetry is enabled, EC2Launch v2 sends telemetry data without additional customer notifications.

Telemetry visibility

When telemetry is enabled, it appears in the Amazon EC2 console output as follows.

```
2021/07/15 21:44:12Z: Telemetry: <Data>
```

Disable telemetry on an instance

To disable telemetry for a single instance, you can either set a system environment variable, or use the MSI to modify the installation.

To disable telemetry by setting a system environment variable, run the following command as an administrator.

```
setx /M EC2LAUNCH_TELEMETRY 0
```

To disable telemetry using the MSI, run the following command after you [download the MSI \(p. 697\)](#).

```
msiexec /i ".\AmazonEC2Launch.msi" Remove="Telemetry" /q
```

Install the latest version of EC2Launch v2

You can use one of the following methods to install the EC2Launch v2 agent on your EC2 instance:

- Download the agent from Amazon S3 and install with Windows PowerShell. For download URLs, see [EC2Launch v2 downloads on Amazon S3 \(p. 698\)](#).
- Install with SSM Distributor.
- Install from an EC2 Image Builder component.
- Launch your instance from an AMI that has EC2Launch v2 pre-installed.

Warning

AmazonEC2Launch.msi uninstalls previous versions of the EC2 launch services, such as EC2Launch (v1) and EC2Config.

For install steps, select the tab that matches your preferred method.

Windows PowerShell

To install the latest version of EC2Launch v2 agent with Windows PowerShell, follow these steps.

1. Create your local directory.

```
New-Item -Path "$env:USERPROFILE\Desktop\EC2Launchv2" -ItemType Directory
```

2. Set the URL for your download location. Run the following command with the Amazon S3 URL you'll use. For download URLs, see [EC2Launch v2 downloads on Amazon S3 \(p. 698\)](#)

```
$Url = "Amazon S3 URL/AmazonEC2Launch.msi"
```

3. Use the following compound command to download the agent and run the install

```
$DownloadFile = "$env:USERPROFILE\Desktop\EC2Launchv2\" + $(Split-Path -Path $Url - Leaf)  
Invoke-WebRequest -Uri $Url -OutFile $DownloadFile  
msiexec /i "$DownloadFile"
```

4. To verify the install, check that the msi file exists in the EC2Launch v2 directory on your instance (C:\ProgramData\Amazon\EC2Launch).

AWS Systems Manager Distributor

You can install the AWSEC2Launch-Agent package from AWS Systems Manager Distributor. For instructions on how to install a package from Systems Manager Distributor, see [Install or update packages](#) in the *AWS Systems Manager User Guide*.

EC2 Image Builder component

You can install the ec2launch-v2-windows component when you build a custom image with EC2 Image Builder. For instructions on how to build a custom image with EC2 Image Builder, see [Create an image pipeline using the EC2 Image Builder console wizard](#) in the *EC2 Image Builder User Guide*.

AMI

EC2Launch v2 is preinstalled by default on the following Windows Server 2022 and UEFI AMIs:

- Windows_Server-2022-English-Full-Base
- Windows_Server-2022-English-Core-Base

- Windows Server 2022 AMIs with all other languages
- Windows Server 2022 AMIs with SQL installed
- Windows_Server-2022-English-Core-EKS_Optimized

EC2Launch v2 is also preinstalled on the following Windows Server AMIs. You can find these AMIs from the Amazon EC2 console, or by using the following search prefix: EC2LaunchV2- in the AWS CLI.

- EC2LaunchV2-Windows_Server-2019-English-Core-Base
- EC2LaunchV2-Windows_Server-2019-English-Full-Base
- EC2LaunchV2-Windows_Server-2016-English-Core-Base
- EC2LaunchV2-Windows_Server-2016-English-Full-Base
- EC2LaunchV2-Windows_Server-2012_R2_RTM-English-Full-Base
- EC2LaunchV2-Windows_Server-2012_RTM-English-Full-Base

EC2Launch v2 downloads on Amazon S3

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](#).

To install the latest version of EC2Launch v2, download the installer from one of the following locations:

Note

The 32-bit installation link will be deprecated. We recommend that you use the 64-bit installation link to install EC2Launch v2. If you require a 32-bit launch agent, use [EC2Config \(p. 753\)](#).

- **64Bit** — <https://s3.amazonaws.com/amazon-ec2launch-v2/windows/amd64/latest/AmazonEC2Launch.msi>
- **32Bit** — <https://s3.amazonaws.com/amazon-ec2launch-v2/windows/386/latest/AmazonEC2Launch.msi>

Configure install options

When you install or upgrade EC2Launch v2, you can configure installation options with the EC2Launch v2 install dialog or with the **msiexec** command in a command line shell.

The first time the EC2Launch v2 installer runs on an instance, it initializes launch agent settings on your instance as follows:

- It creates the local path and writes the launch agent file to it. This is sometimes referred to as a *clean install*.
- It creates the EC2LAUNCH_TELEMETRY environment variable if it doesn't already exist, and sets it based on your configuration.

For configuration details, select the tab that matches the configuration method that you'll use.

Amazon EC2Launch Setup dialog

When you install or upgrade EC2Launch v2, you can configure the following installation options through the EC2Launch v2 install dialog.

Basic Install options

Send Telemetry

When you include this feature in the setup dialog, the installer sets the EC2LAUNCH_TELEMETRY environment variable to a value of 1. If you disable **Send Telemetry**, the installer sets the environment variable to a value of 0.

When the EC2Launch v2 agent runs, it reads the EC2LAUNCH_TELEMETRY environment variable to determine whether to upload telemetry data. If the value equals 1, it uploads the data. Otherwise, it doesn't upload.

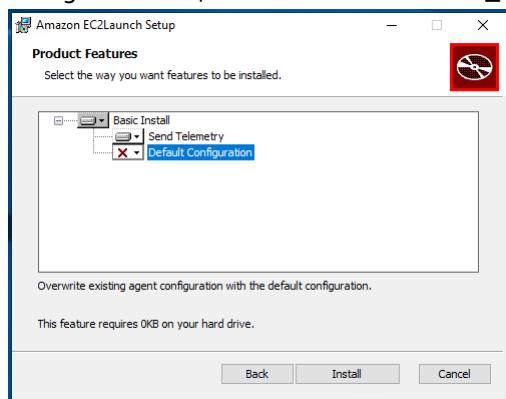

Default configuration

The default configuration for EC2Launch v2 is to overwrite the local launch agent if it exists already. The first time you run an install on an instance, the default configuration performs a clean install. If you disable the default configuration on the initial install, the installation fails.

If you run the install again on the instance, you can disable the default configuration to perform an upgrade that doesn't replace the %ProgramData%/*Amazon/EC2Launch/config/agent-config.yml* file.

Example: Upgrade EC2Launch v2 with telemetry

The following example shows the EC2Launch v2 setup dialog configured to upgrade the current installation and enable telemetry. This configuration performs an install without replacing the agent configuration file, and sets the EC2LAUNCH_TELEMETRY environment variable to a value of 1.

Command line

When you install or upgrade EC2Launch v2, you can configure the following installation options with the **msiexec** command in a command line shell.

ADDLOCAL parameter values

Basic (required)

Install the launch agent. If this value is not present in the ADDLOCAL parameter, the installation ends.

Clean

When you include the Clean value in the ADDLOCAL parameter, the installer writes the agent configuration file to the following location: %ProgramData%/*Amazon/EC2Launch/config/agent-config.yml*. If the agent configuration file already exists, it overwrites the file.

When you leave the Clean value out of the ADDLOCAL parameter, the installer performs an upgrade that doesn't replace the agent configuration file.

Telemetry

When you include the Telemetry value in the ADDLOCAL parameter, the installer sets the EC2LAUNCH_TELEMETRY environment variable to a value of 1.

When you leave the Telemetry value out of the ADDLOCAL parameter, the installer sets the environment variable to a value of 0.

When the EC2Launch v2 agent runs, it reads the EC2LAUNCH_TELEMETRY environment variable to determine whether to upload telemetry data. If the value equals 1, it uploads the data. Otherwise, it doesn't upload.

Example: install EC2Launch v2 with telemetry

```
& msiexec /i "C:\Users\Administrator\Desktop\EC2Launchv2\AmazonEC2Launch.msi"  
ADDLOCAL="Basic,Clean,Telemetry" /q
```

Verify the EC2Launch v2 version

Use one of the following procedures to verify the version of EC2Launch v2 that is installed on your instances.

Windows PowerShell

Verify the installed version of EC2Launch v2 with Windows PowerShell, as follows.

1. Launch an instance from your AMI and connect to it.
2. Run the following command in PowerShell to verify the installed version of EC2Launch v2:

```
& "C:\Program Files\Amazon\EC2Launch\EC2Launch.exe" version
```

Windows Control Panel

Verify the installed version of EC2Launch v2 in the Windows Control Panel, as follows.

1. Launch an instance from your AMI and connect to it.
2. Open the Windows Control Panel and choose **Programs and Features**.
3. Look for Amazon EC2Launch in the list of installed programs. Its version number appears in the **Version** column.

For information about the EC2Launch v2 versions included in the Windows AMIs, see [AWS Windows AMIs \(p. 41\)](#).

For the latest version of EC2Launch v2, see [EC2Launch v2 version history \(p. 739\)](#).

For the latest version of the EC2Launch v2 migration tool, see [EC2Launch v2 migration tool version history \(p. 742\)](#).

You can receive notifications when new versions of the EC2Launch v2 service are released. For more information, see [Subscribe to EC2Launch v2 service notifications \(p. 702\)](#).

Migrate to EC2Launch v2

The EC2Launch migration tool upgrades the installed launch agent (EC2Config and EC2Launch v1) by uninstalling it and installing EC2Launch v2. Applicable configurations from previous launch

services are automatically migrated to the new service. The migration tool does not detect any scheduled tasks linked to EC2Launch v1 scripts; therefore, it does not automatically set up those tasks in EC2Launch v2. To configure these tasks, edit the [agent-config.yml \(p. 716\)](#) file, or use the [EC2Launch v2 settings dialog box \(p. 703\)](#). For example, if an instance has a scheduled task that runs `InitializeDisks.ps1`, then after you run the migration tool, you must specify the volumes you want to initialize in the EC2Launch v2 settings dialog box. See Step 6 of the procedure to [Change settings using the EC2Launch v2 settings dialog box \(p. 703\)](#).

You can download the migration tool or install with an SSM RunCommand document.

You can download the tool from the following locations:

Note

The 32-bit migration tool link will be deprecated. We recommend that you use the 64-bit link to migrate to EC2Launch v2. If you require a 32-bit launch agent, use [EC2Config \(p. 753\)](#).

- **64Bit** — <https://s3.amazonaws.com/amazon-ec2launch-v2-utils/MigrationTool/windows/amd64/latest/EC2LaunchMigrationTool.zip>
- **32Bit** — <https://s3.amazonaws.com/amazon-ec2launch-v2-utils/MigrationTool/windows/386/latest/EC2LaunchMigrationTool.zip>

Note

You must run the EC2Launch v2 migration tool as an Administrator. EC2Launch v2 is installed as a service after you run the migration tool. It does not run immediately. By default, it runs during instance startup and runs if an instance is stopped and later started, or restarted.

Use the [AWSEC2Launch-RunMigration](#) SSM document to migrate to the latest EC2Launch v2 version with SSM Run Command. The document does not require any parameters. For more information about using SSM Run Command, see [AWS Systems Manager Run Command](#).

The migration tool applies the following configurations from EC2Config to EC2Launch v2.

- If `Ec2DynamicBootVolumeSize` is set to `false`, removes EC2Launch v2 boot stage
- If `Ec2SetPassword` is set to `Enabled`, sets EC2Launch v2 password type to `random`
- If `Ec2SetPassword` is set to `Disabled`, sets EC2Launch v2 password type to `donothing`
- If `SetDnsSuffixList` is set to `false`, removes EC2Launch v2 `setDnsSuffix` task
- If `EC2SetComputerName` is set to `true`, adds EC2Launch v2 `setHostName` task to `yaml` configuration

The migration tool applies the following configurations from EC2Launch v1 to EC2Launch v2.

- If `ExtendBootVolumeSize` is set to `false`, removes EC2Launch v2 boot stage
- If `AdminPasswordType` is set to `Random`, sets EC2Launch v2 password type to `random`
- If `AdminPasswordType` is set to `Specify`, sets EC2Launch v2 password type to `static` and password data to the password specified in `AdminPassword`
- If `SetWallpaper` is set to `false`, removes EC2Launch v2 `setWallpaper` task
- If `AddDnsSuffixList` is set to `false`, removes EC2Launch v2 `setDnsSuffix` task
- If `SetComputerName` is set to `true`, adds EC2Launch v2 `setHostName` task

Stop, restart, delete, or uninstall EC2Launch v2

You can manage the EC2Launch v2 service just as you would any other Windows service.

EC2Launch v2 runs once on boot and runs all of the configured tasks. After executing tasks, the service enters a stopped state. When you restart the service, the service will run all of the configured tasks again and return to a stopped state.

To apply updated settings to your instance, you can stop and restart the service. If you are manually installing EC2Launch v2, you must first stop the service first.

To stop the EC2Launch v2 service

1. Launch and connect to your Windows instance.
2. On the **Start** menu, choose **Administrative Tools**, and then open **Services**.
3. In the list of services, right-click **Amazon EC2Launch**, and select **Stop**.

To restart the EC2Launch v2 service

1. Launch and connect to your Windows instance.
2. On the **Start** menu, choose **Administrative Tools**, and then open **Services**.
3. In the list of services, right-click **Amazon EC2Launch**, and select **Restart**.

If you don't need to update the configuration settings, create your own AMI, or use AWS Systems Manager, you can delete and uninstall the service. Deleting a service removes its registry subkey. Uninstalling a service removes the files, the registry subkeys, and any shortcuts to the service.

To delete the EC2Launch v2 service

1. Start a command prompt window.
2. Run the following command:

```
sc delete EC2Launch
```

To uninstall EC2Launch v2

1. Launch and connect to your Windows instance.
2. On the **Start** menu, choose **Control Panel**.
3. Open **Programs** and then **Programs and Features**.
4. In the list of programs, choose **Amazon EC2Launch**. To confirm that you're choosing v2, check the **Version** column.
5. Choose **Uninstall**.

Subscribe to EC2Launch v2 service notifications

Amazon SNS can notify you when new versions of the EC2Launch v2 service are released. Use the following procedure to subscribe to these notifications.

Subscribe to EC2Launch v2 notifications

1. Sign in to the AWS Management Console and open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must select this Region because the SNS notifications that you are subscribing to were created in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. In the Create subscription dialog box, do the following:

- a. For **Topic ARN**, use the following Amazon Resource Name (ARN): **arn:aws:sns:us-east-1:309726204594:amazon-ec2launch-v2**.
 - b. For **Protocol**, choose **Email**.
 - c. For **Endpoint**, enter an email address that you can use to receive the notifications.
 - d. Choose **Create subscription**.
6. You'll receive an email asking you to confirm your subscription. Open the email and follow the directions to complete your subscription.

Whenever a new version of the EC2Launch v2 service is released, we send notifications to subscribers. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

1. Open the Amazon SNS console.
2. In the navigation pane, choose **Subscriptions**.
3. Select the subscription and then choose **Actions, Delete subscriptions**. When prompted for confirmation, choose **Delete**.

EC2Launch v2 settings

This section contains information about how to configure settings for EC2Launch v2.

Topics include:

- [Change settings using the EC2Launch v2 settings dialog box \(p. 703\)](#)
- [EC2Launch v2 directory structure \(p. 709\)](#)
- [Configure EC2Launch v2 using the CLI \(p. 710\)](#)
- [EC2Launch v2 task configuration \(p. 716\)](#)
- [EC2Launch v2 exit codes and reboots \(p. 730\)](#)
- [EC2Launch v2 and Sysprep \(p. 730\)](#)

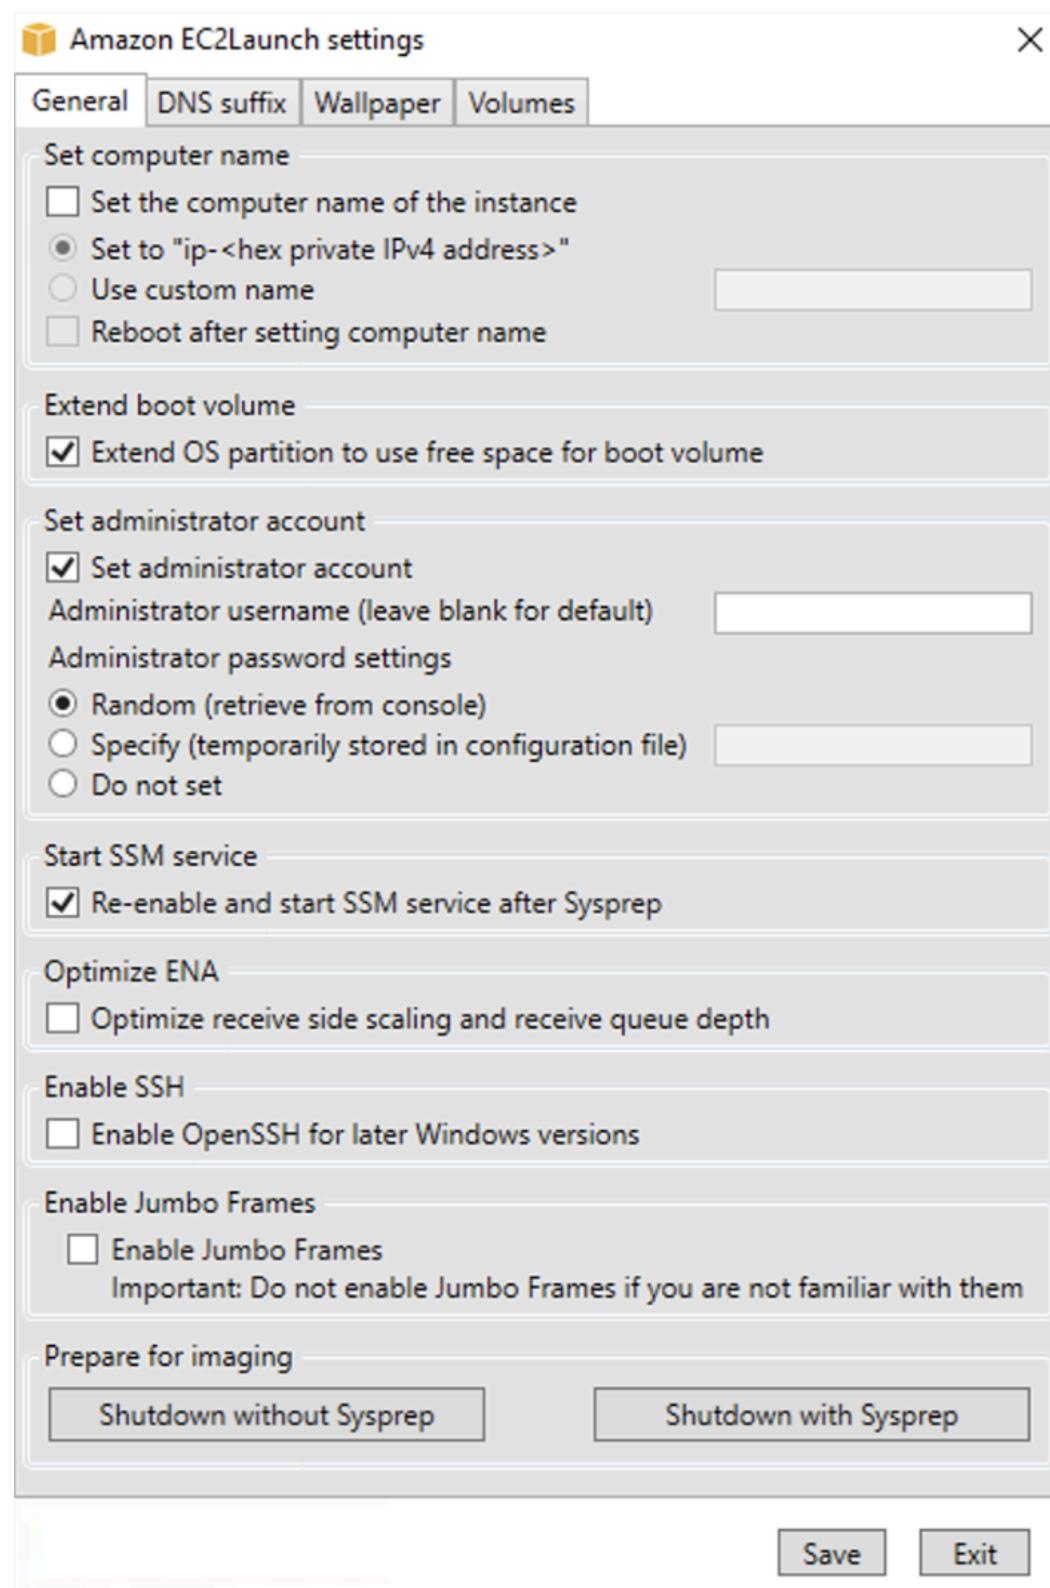

Change settings using the EC2Launch v2 settings dialog box

The following procedure describes how to use the EC2Launch v2 settings dialog box to enable or disable settings.

Note

If you improperly configure custom tasks in the agent-config.yml file, and you attempt to open the Amazon EC2Launch settings dialog box, you will receive an error. For example schema, see [Example: agent-config.yml \(p. 716\)](#).

1. Launch and connect to your Windows instance.
2. From the Start menu, choose **All Programs**, and then navigate to **EC2Launch settings**.

3. On the **General** tab of the **EC2Launch settings** dialog box, you can enable or disable the following settings.

a. **Set Computer Name**

If this setting is enabled (it is disabled by default), the current host name is compared to the desired host name at each boot. If the host names do not match, the host name is reset, and the system then optionally reboots to pick up the new host name. If a custom host name is not specified, it is generated using the hexadecimal-formatted private IPv4 address, for example, ip-AC1F4E6. To prevent your existing host name from being modified, do not enable this setting.

b. **Extend Boot Volume**

This setting dynamically extends Disk 0/Volume 0 to include any unpartitioned space. This can be useful when the instance is booted from a root device volume that has a custom size.

c. **Set Administrator Account**

When enabled, you can set the username and password attributes for the administrator account that is created on your local machine. If this feature is not enabled, an administrator account is not created on the system following Sysprep. Provide a password in adminPassword only if adminPasswordtype is Specify.

The password types are defined as follows:

i. **Random**

EC2Launch generates a password and encrypts it using the user's key. The system disables this setting after the instance is launched so that this password persists if the instance is rebooted or stopped and started.

ii. **Specify**

EC2Launch uses the password that you specify in adminPassword. If the password does not meet the system requirements, EC2Launch generates a random password instead. The password is stored in agent-config.yml as clear text and is deleted after Sysprep sets the administrator password. EC2Launch encrypts the password using the user's key.

iii. **DoNothing**

EC2Launch uses the password that you specify in the unattend.xml file. If you don't specify a password in unattend.xml, the administrator account is disabled.

d. **Start SSM Service**

When selected, the Systems Manager service is enabled to start following Sysprep. EC2Launch v2 performs all of the tasks described [earlier \(p. 695\)](#), and the SSM Agent processes requests for Systems Manager capabilities, such as Run Command and State Manager.

You can use Run Command to upgrade your existing instances to use the latest version of the EC2Launch v2 service and SSM Agent. For more information, see [Update SSM Agent by using Run Command](#) in the *AWS Systems Manager User Guide*.

e. **Optimize ENA**

When selected, ENA settings are configured to ensure that ENA Receive Side Scaling and Receive Queue Depth settings are optimized for AWS. For more information, see [Configure RSS CPU affinity \(p. 1349\)](#).

f. **Enable SSH**

This setting enables OpenSSH for later Windows versions to allow for remote system administration.

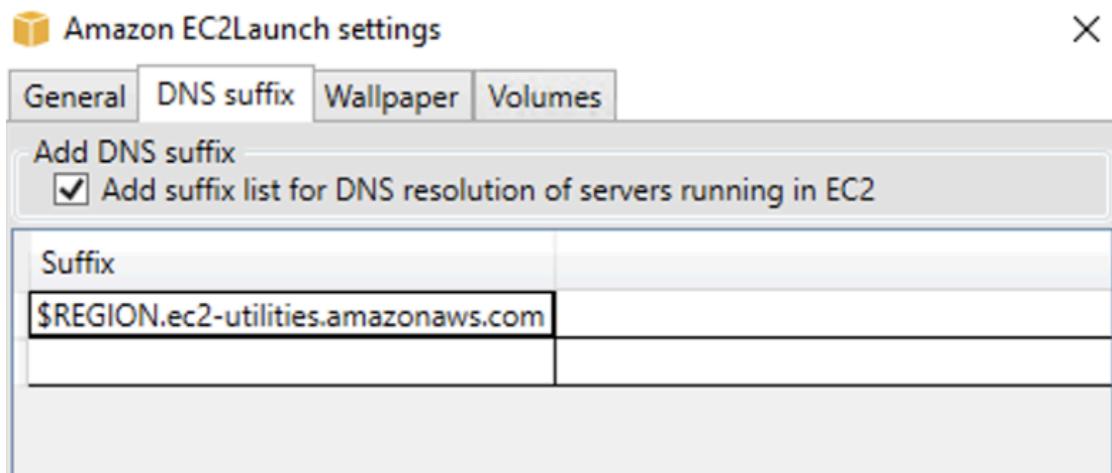

g. **Enable Jumbo Frames**

Select to enable Jumbo Frames. Jumbo Frames can have unintended effects on your network communications, so ensure you understand how Jumbo Frames will impact your system before enabling. For more information about Jumbo Frames, see [Jumbo frames \(9001 MTU\) \(p. 1369\)](#).

h. **Prepare for Imaging**

Select whether you want your EC2 instance to shut down with or without Sysprep. When you want to run Sysprep with EC2Launch v2, choose **Shutdown with Sysprep**.

4. On the **DNS Suffix** tab, you can select whether you want to add a DNS suffix list for DNS resolution of servers running in EC2, without providing the fully qualified domain name. DNS suffixes can contain the variables \$REGION and \$AZ. Only suffixes that do not already exist will be added to the list.

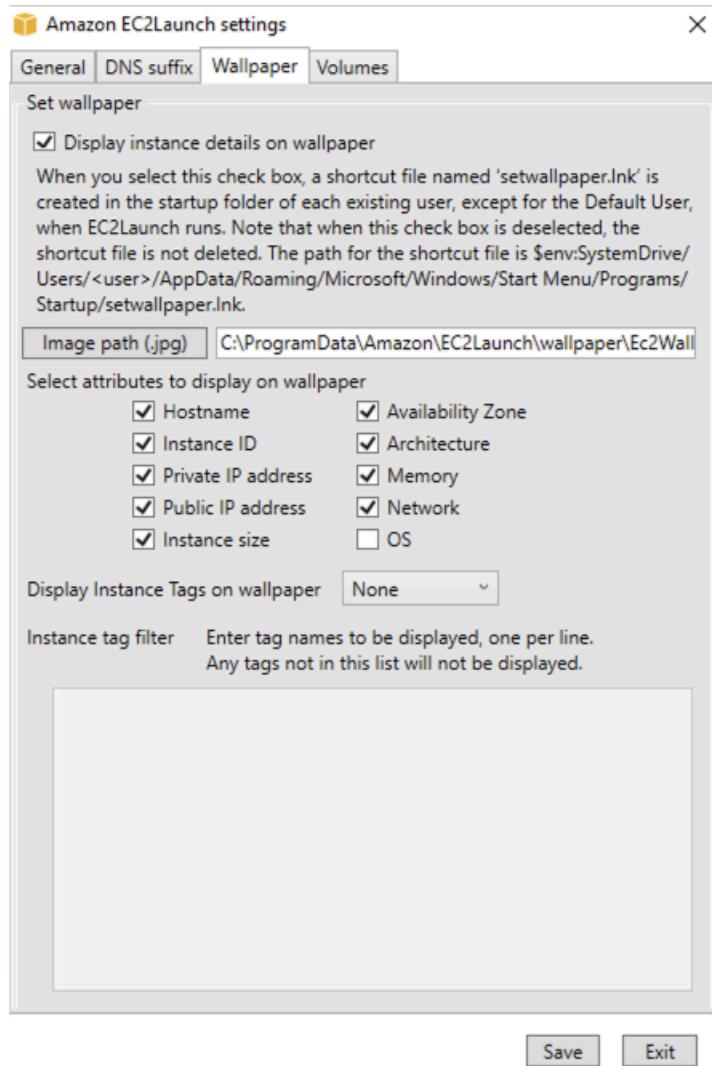

5. On the **Wallpaper** tab, you can configure your instance wallpaper with a background image, and specify instance details for the wallpaper to display. Amazon EC2 generates the details each time you log in.

You can configure your wallpaper with the following controls.

- **Display instance details on wallpaper** – This checkbox activates or deactivates instance detail display on the wallpaper.
- **Image path (.jpg)** – Specify the path to the image to use as the wallpaper background.
- **Select attributes to display on wallpaper** – Select the check boxes for the instance details that you want to appear on the wallpaper. Clear the check boxes for previously selected instance details that you want to remove from the wallpaper.
- **Display Instance Tags on wallpaper** – Select one of the following settings to display instance tags on the wallpaper:
 - **None** – Don't display any instance tags on the wallpaper.
 - **Show all** – Display all instance tags on the wallpaper.
 - **Show filtered** – Display specified instance tags on the wallpaper. When you select this setting, you can add instance tags that you want to display on your wallpaper in the **Instance tag filter** box.

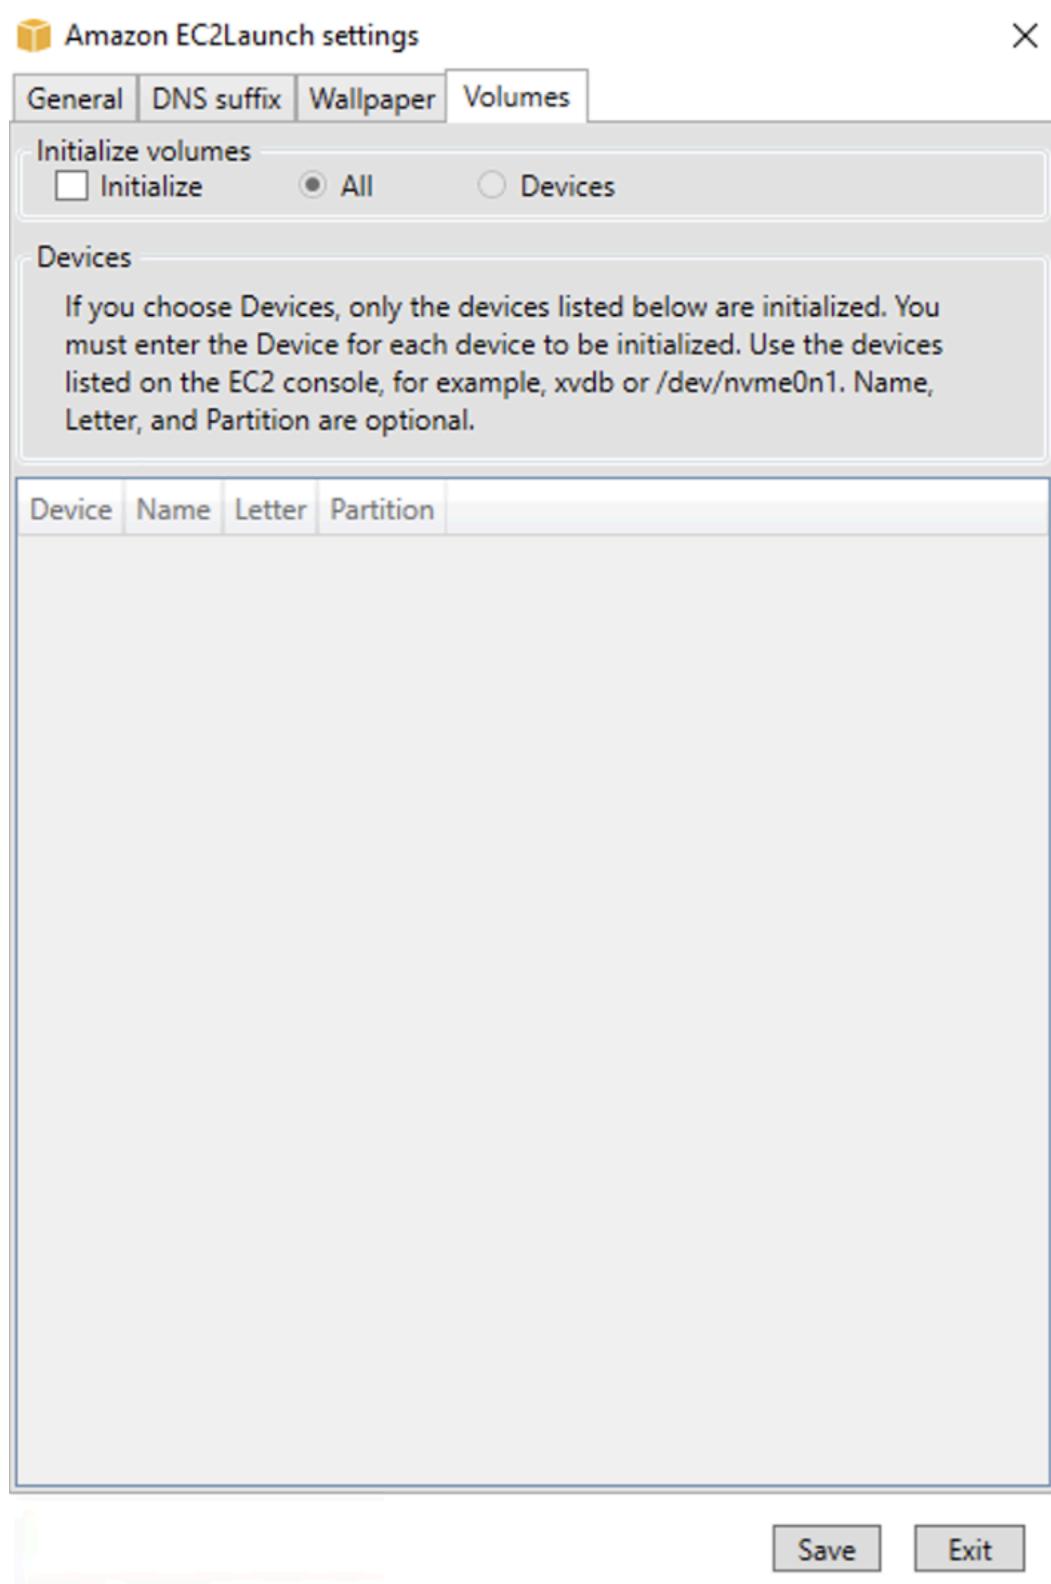

Note

You must enable tags in metadata to show tags on the wallpaper. For more information about instance tags and metadata, see [Work with instance tags in instance metadata \(p. 2097\)](#).

6. On the **Volumes** tab, select whether you want to initialize the volumes that are attached to the instance. Enabling sets drive letters for any additional volumes and extends them to use available space. If you select **All**, all of the storage volumes are initialized. If you select **Devices**, only devices that are specified in the list are initialized. You must enter the device for each device to be initialized. Use the devices listed on the EC2 console, for example, xvdb or /dev/nvme0n1. The dropdown list displays the storage volumes that are attached to the instance. To enter a device that is not attached to the instance, enter it in the text field.

Name, **Letter**, and **Partition** are optional fields. If no value is specified for **Partition**, storage volumes larger than 2 TB are initialized with the GPT partition type, and those smaller than 2 TB are initialized with the MBR partition type. If devices are configured, and a non-NTFS device either contains a partition table, or the first 4 KB of the disk contain data, then the disk is skipped and the action logged.

The following is an example configuration YAML file created from the settings entered in the EC2Launch dialog.

```
version: 1.0
config:
  - stage: boot
    tasks:
      - task: extendRootPartition
  - stage: preReady
    tasks:
      - task: activateWindows
        inputs:
          activation:
            type: amazon
      - task: setDnsSuffix
        inputs:
          suffixes:
            - $REGION.ec2-utilities.amazonaws.com
  - task: setAdminAccount
    inputs:
      password:
        type: random
  - task: setWallpaper
    inputs:
      path: C:\ProgramData\Amazon\EC2Launch\wallpaper\Ec2Wallpaper.jpg
      attributes:
        - hostName
        - instanceId
        - privateIpAddress
        - publicIpAddress
        - instanceSize
        - availabilityZone
        - architecture
        - memory
        - network
  - stage: postReady
    tasks:
      - task: startSsm
```

EC2Launch v2 directory structure

EC2Launch v2 should be installed in the following directories:

- Service binaries: %ProgramFiles%\Amazon\EC2Launch
- Service data (settings, log files, and state files): %ProgramData%\Amazon\EC2Launch

Note

By default, Windows hides files and folders under C:\ProgramData. To view EC2Launch v2 directories and files, you must either enter the path in Windows Explorer or change the folder properties to show hidden files and folders.

The %ProgramFiles%\Amazon\EC2Launch directory contains binaries and supporting libraries. It includes the following subdirectories:

- **settings**
 - EC2LaunchSettingsUI.exe — user interface for modifying the agent-config.yml file
 - YamlDotNet.dll — DLL for supporting some operations in the user interface
- **tools**
 - ebsnvme-id.exe — tool for examining the metadata of the EBS volumes on the instance

- AWSACpiSpcrReader.exe — tool for determining the correct COM port to use
- EC2LaunchEventMessage.dll — DLL for supporting the Windows event logging for EC2Launch.
- service
 - EC2LaunchService.exe — Windows service executable that is launched when the launch agent runs as a service.
- EC2Launch.exe — main EC2Launch executable
- EC2LaunchAgentAttribution.txt — attribution for code used within EC2 Launch

The %ProgramData%\Amazon\EC2Launch directory contains the following subdirectories. All of the data produced by the service, including logs, configuration, and state, is stored in this directory.

- config — Configuration

The service configuration file is stored in this directory as agent-config.yml. This file can be updated to modify, add, or remove default tasks run by the service. Permission to create files in this directory is restricted to the administrator account to prevent privilege escalation.

- log — Instance logs

Logs for the service (agent.log), console (console.log), performance (bench.log), and errors (error.log) are stored in this directory. Log files are appended to on subsequent executions of the service.

- state — Service state data

The state that the service uses to determine which tasks should run is stored here. There is a .run-once file that indicates whether the service has already run after Sysprep (so tasks with a frequency of once will be skipped on the next run). This subdirectory includes a state.json and previous-state.json to track the status of each task.

- sysprep — Sysprep

This directory contains files that are used to determine which operations to perform by Sysprep when it creates a customized Windows AMI that can be reused.

Configure EC2Launch v2 using the CLI

You can use the Command Line Interface (CLI) to configure your EC2Launch settings and manage the service. The following section contains descriptions and usage information for the CLI commands that you can use to manage EC2Launch v2.

Commands

- [collect-logs \(p. 711\)](#)
- [get-agent-config \(p. 711\)](#)
- [list-volumes \(p. 712\)](#)
- [reset \(p. 712\)](#)
- [run \(p. 713\)](#)
- [status \(p. 713\)](#)
- [sysprep \(p. 714\)](#)
- [validate \(p. 714\)](#)
- [version \(p. 715\)](#)
- [wallpaper \(p. 715\)](#)

collect-logs

Collects log files for EC2Launch, zips the files, and places them in a specified directory.

Example

```
ec2launch collect-logs -o C:\Mylogs.zip
```

Usage

```
ec2launch collect-logs [flags]
```

Flags

-h, --help

help for collect-logs

-o, --output string

path to zipped output log files

get-agent-config

Prints agent-config.yml in the format specified (JSON or YAML). If no format is specified, agent-config.yml is printed in the format previously specified.

Example

```
ec2launch get-agent-config -f json
```

Example 2

The following PowerShell commands show how to edit and save the agent-config file in JSON format.

```
$config = ec2launch get-agent-config --format json | ConvertFrom-Json
$jumboFrame =@"
{
    "task": "enableJumboFrames"
}
$config.config | %{$_.stage -eq 'postReady'){$_.tasks += (ConvertFrom-Json -InputObject
$jumboFrame)}}
$config | ConvertTo-Json -Depth 6 | Out-File -encoding UTF8 $env:ProgramData/Amazon/
EC2Launch/config/agent-config.yml
```

Usage

```
ec2launch get-agent-config [flags]
```

Flags

-h, --help

help for get-agent-config

-f, --format string

output format of agent-config file: json, yaml

list-volumes

Lists all of the storage volumes attached to the instance, including ephemeral and EBS volumes.

Example

```
ec2launch list-volumes
```

Usage

```
ec2launch list-volumes
```

Flags

-h, --help

help for list-volumes

reset

The main goal of this task is to reset the agent for the next time that it runs. To do that, the **reset** command deletes all of the agent state data for EC2Launch v2 from the local EC2Launch directory (see [EC2Launch v2 directory structure \(p. 709\)](#)). Reset optionally deletes the service and Sysprep logs.

Script behavior depends on what mode the agent runs the scripts in – inline, or detached.

Inline (default)

The EC2Launch v2 agent runs scripts one at a time (`detach: false`). This is the default setting.

Note

When your inline script issues a **reset** or **sysprep** command, it runs immediately and resets the agent. The current task finishes, then the agent shuts down without running any further tasks.

For example, if the task that issues the command would have been followed by a `startSsm` task (included by default after user data runs), the task doesn't run and the Systems Manager service never starts.

Detached

The EC2Launch v2 agent runs scripts concurrently with other tasks (`detach: true`).

Note

When your detached script issues a **reset** or **sysprep** command, those commands wait for the agent to finish before they run. Tasks after the `executeScript` will still run.

Example

```
ec2launch reset -c
```

Usage

```
ec2launch reset [flags]
```

Flags

-c, --clean

cleans instance logs before reset

-h, --help

help for reset

run

Runs EC2Launch v2.

Example

```
ec2launch run
```

Usage

ec2launch run [flags]

Flags

-h, --help

help for run

status

Gets the status of the EC2Launch v2 agent. Optionally blocks the process until the agent is finished. The process exit code determines the agent state:

- 0 –the agent ran and was successful.
- 1 – the agent ran and failed.
- 2 – the agent is still running.
- 3 – the agent is in an unknown state. The agent state is not running or stopped.
- 4 – an error occurred when attempting to retrieve the agent state.
- 5 – the agent is not running and the status of the last known run is unknown. This could mean one of the following:
 - both the state.json and previous-state.json are deleted.
 - the previous-state.json is corrupted.

This is the agent state after running the [reset \(p. 712\)](#) command.

Example:

```
ec2launch status -b
```

Usage

ec2launch status [flags]

Flags

-b,--block

blocks the process until the agent finishes running

-h,--help

help for status

sysprep

The main goal of this task is to reset the agent for the next time that it runs. To do that, the **sysprep** command resets the agent state, updates the `unattend.xml` file, disables RDP, and runs Sysprep.

Script behavior depends on what mode the agent runs the scripts in – inline, or detached.

Inline (default)

The EC2Launch v2 agent runs scripts one at a time (`detach: false`). This is the default setting.

Note

When your inline script issues a **reset** or **sysprep** command, it runs immediately and resets the agent. The current task finishes, then the agent shuts down without running any further tasks.

For example, if the task that issues the command would have been followed by a `startSsm` task (included by default after user data runs), the task doesn't run and the Systems Manager service never starts.

Detached

The EC2Launch v2 agent runs scripts concurrently with other tasks (`detach: true`).

Note

When your detached script issues a **reset** or **sysprep** command, those commands wait for the agent to finish before they run. Tasks after the `executeScript` will still run.

Example:

```
ec2launch sysprep
```

Usage

```
ec2launch sysprep [flags]
```

Flags

```
-c,--clean
```

cleans instance logs before sysprep

```
-h,--help
```

help for Sysprep

```
-s,--shutdown
```

shuts down the instance after sysprep

validate

Validates the agent-config file `C:\ProgramData\Amazon\EC2Launch\config\agent-config.yml`.

Example

```
ec2launch validate
```

Usage

```
ec2launch validate [flags]
```

Flags

-h , --help

help for validate

version

Gets the executable version.

Example

```
ec2launch version
```

Usage

```
ec2launch version [flags]
```

Flags

-h, --help

help for version

wallpaper

Sets new wallpaper to the wallpaper path that is provided (.jpg file), and displays the selected instance details.

Syntax

```
ec2launch wallpaper ^
--path="C:\ProgramData\Amazon\EC2Launch\wallpaper\Ec2Wallpaper.jpg" ^
--all-tags ^
--
attributes=hostName,instanceId,privateIpAddress,publicIpAddress,instanceSize,availabilityZone,architect
```

Inputs

Parameters

--allowed-tags [*tag-name-1, tag-name-n*]

(Optional) Base64 encoded JSON array of instance tag names to display on the wallpaper. You can use this tag or the --all-tags, but not both.

--attributes *attribute-string-1, attribute-string-n*

(Optional) A comma-separated list of wallpaper attribute strings to apply settings to the wallpaper.

[--path | -p] *path-string*

(Required) Specifies the wallpaper background image file path.

Flags

--all-tags

(Optional) Displays all of the instance tags on the wallpaper. You can use this tag or the --allowed-tags, but not both.

[--help | -h]

Displays help for the **wallpaper** command.

EC2Launch v2 task configuration

This section includes the configuration schema, tasks, details, and examples for `agent-config.yml` and user data.

Tasks and examples

- [Schema: agent-config.yml \(p. 716\)](#)
- [Schema: user data \(p. 717\)](#)
- [Task definitions \(p. 719\)](#)

Schema: `agent-config.yml`

The structure of the `agent-config.yml` file is shown below. Note that a task cannot be repeated in the same stage. For task properties, see the task descriptions that follow.

Document structure: `agent-config.yml`

JSON

```
{  
  "version": "1.0",  
  "config": [  
    {  
      "stage": "string",  
      "tasks": [  
        {  
          "task": "string",  
          "inputs": {  
            ...  
          }  
        },  
        ...  
      ]  
    },  
    ...  
  ]  
}
```

YAML

```
version: 1.0  
config:  
- stage: string  
  tasks:  
    - task: string  
  inputs:  
    ...  
    ...  
  ...
```

Example: `agent-config.yml`

The following example shows settings for the `agent-config.yml` configuration file.

```
version: 1.0
config:
- stage: boot
  tasks:
    - task: extendRootPartition
- stage: preReady
  tasks:
    - task: activateWindows
      inputs:
        activation:
          type: amazon
    - task: setDnsSuffix
      inputs:
        suffixes:
        - $REGION.ec2-utilities.amazonaws.com
- task: setAdminAccount
  inputs:
    password:
      type: random
- task: setWallpaper
  inputs:
    path: C:\ProgramData\Amazon\EC2Launch\wallpaper\Ec2Wallpaper.jpg
    attributes:
    - hostName
    - instanceId
    - privateIpAddress
    - publicIpAddress
    - instanceSize
    - availabilityZone
    - architecture
    - memory
    - network
- stage: postReady
  tasks:
    - task: startSsm
```

Schema: user data

The following JSON and YAML examples show the document structure for user data. Amazon EC2 parses each task named in the tasks array that you specify in the document. Each task has its own set of properties and requirements. For details, see the [Task definitions \(p. 719\)](#).

Note

A task must only appear once in user data tasks array.

Document structure: user data

JSON

```
{
  "version": "1.1",
  "tasks": [
    {
      "task": "string",
      "inputs": {
        ...
      },
      ...
    }
  ]
}
```

YAML

```
version: 1.1
tasks:
- task: string
  inputs:
    ...
  ...
```

Example: user data

For more information about user data, see [Run commands on your Windows instance at launch \(p. 853\)](#).

The following YAML document example shows a PowerShell script that EC2Launch v2 runs as user data to create a file.

```
version: 1.1
tasks:
- task: executeScript
  inputs:
    - frequency: always
      type: powershell
      runAs: localSystem
    content: |-
      New-Item -Path 'C:\PowerShellTest.txt' -ItemType File
```

You can use an XML format for the user data that's compatible with previous versions of the launch agent. EC2Launch v2 runs the script as an executeScript task in the `UserData` stage. To conform with EC2Launch v1 and EC2Config behavior, the user data script runs as an attached/inline process by default.

You can add optional tags to customize how your script runs. For example, to run the user data script when the instance reboots in addition to one time when the instance launches, you can use the following tag:

```
<persist>true</persist>
```

Example:

```
<powershell>
  $file = $env:SystemRoot + "\Temp" + (Get-Date).ToString("MM-dd-yy-hh-mm")
  New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

To run an XML user data script as a detached process, add the following tag to your user data.

```
<detach>true</detach>
```

Example:

```
<powershell>
  $file = $env:SystemRoot + "\Temp" + (Get-Date).ToString("MM-dd-yy-hh-mm")
  New-Item $file -ItemType file
</powershell>
<detach>true</detach>
```

Note

The `detach` tag is not supported on previous launch agents.

Change log: user data

The following table lists changes for user data, and cross-references them to the EC2Launch v2 agent version that applies.

User data version	Details	Introduced in
1.1	<ul style="list-style-type: none">User data tasks run before the PostReady stage in the agent config file.Runs user data before starting the Systems Manager Agent (same behavior as EC2Launch v1 and EC2Config).*	EC2Launch v2 version 2.0.1245
1.0	<ul style="list-style-type: none">Will be deprecated.User data tasks run after the PostReady stage in the agent config file. This is not backwards compatible with EC2Launch v1.Impacted by a race condition between Systems Manager Agent start and user data tasks.	EC2Launch v2 version 2.0.0

* When used with the default agent-config.yml file.

Task definitions

Each task has its own set of properties and requirements. For details, see the individual tasks that you want to include in your document.

Tasks

- [activateWindows \(p. 719\)](#)
- [enableJumboFrames \(p. 720\)](#)
- [enableOpenSsh \(p. 720\)](#)
- [executeProgram \(p. 720\)](#)
- [executeScript \(p. 722\)](#)
- [extendRootPartition \(p. 725\)](#)
- [initializeVolume \(p. 725\)](#)
- [optimizeEna \(p. 726\)](#)
- [setAdminAccount \(p. 726\)](#)
- [setDnsSuffix \(p. 726\)](#)
- [setHostName \(p. 727\)](#)
- [setWallpaper \(p. 727\)](#)
- [startSsm \(p. 729\)](#)
- [sysprep \(p. 729\)](#)
- [writeFile \(p. 729\)](#)

activateWindows

Activates Windows against a set of AWS KMS servers. Activation is skipped if the instance is detected as Bring-Your-Own-License (BYOL).

Frequency — once

AllowedStages — [PreReady]

Inputs —

activation: (map)

type: (string) activation type to use, set to amazon

Example

```
task: activateWindows
inputs:
  activation:
    type: amazon
```

[enableJumboFrames](#)

Enables Jumbo Frames, which increase the maximum transmission unit (MTU) of the network adapter. For more information, see [Jumbo frames \(9001 MTU\) \(p. 1369\)](#).

Frequency — always

AllowedStages — [PostReady, UserData]

Inputs — none

Example

```
task: enableJumboFrames
```

[enableOpenSsh](#)

Enables Windows OpenSSH and adds the public key for the instance to the authorized keys folder.

Frequency — once

AllowedStages — [PreReady, UserData]

Inputs — none

Example

The following example shows how to enable OpenSSH on an instance, and to add the public key for the instance to the authorized keys folder. This configuration works only on instances running Windows Server 2019 and later versions.

```
task: enableOpenSsh
```

[executeProgram](#)

Runs a program with optional arguments and a specified frequency.

Stages: You can run the executeProgram task during the PreReady, PostReady, and UserData stages.

Frequency: configurable, see *Inputs*.

Inputs

You can configure runtime parameters as follows:

frequency (string)

(Required) Specify exactly one of the following values:

- once
- always

path (string)

(Required) The file path for the executable to run.

arguments (list of strings)

(Optional) A comma separated list of arguments to provide to the program as input.

runAs (string)

(Required) Must be set to localSystem

Output

All of the tasks write logfile entries to the agent.log file. Additional output from the executeProgram task is stored separately in a dynamically named folder, as follows:

%LocalAppData%\Temp\EC2Launch#####\outputfilename.tmp

The exact path to the output files is included in the agent.log file, for example:

```
Program file is created at: C:\Windows\system32\config\systemprofile\AppData\Local\Temp\EC2Launch123456789\ExecuteProgramInputs.tmp
Output file is created at: C:\Windows\system32\config\systemprofile\AppData\Local\Temp\EC2Launch123456789\Output.tmp
Error file is created at: C:\Windows\system32\config\systemprofile\AppData\Local\Temp\EC2Launch123456789\Err.tmp
```

Output files for the executeProgram task

ExecuteProgramInputs.tmp

Contains the path for the executable, and all of the input parameters that the executeProgram task passes to it when it runs.

Output.tmp

Contains runtime output from the program that the executeProgram task runs.

Err.tmp

Contains runtime error messages from the program that the executeProgram task runs.

Examples

The following examples show how to run an executable file from a local directory on an instance with the executeProgram task.

Example 1: Setup executable with one argument

This example shows an executeProgram task that runs a setup executable in quiet mode.

```
task: executeProgram
inputs:
- frequency: always
```

```
path: C:\Users\Administrator\Desktop\setup.exe
arguments: ['-quiet']
```

Example 2: VLC executable with two arguments

This example shows an executeProgram task that runs a VLC executable file with two arguments passed as input parameters.

```
task: executeProgram
inputs:
- frequency: always
  path: C:\vlc-3.0.11-win64.exe
  arguments: ['/L=1033','/S']
  runAs: localSystem
```

executeScript

Runs a script with optional arguments and a specified frequency. Script behavior depends on what mode the agent runs the scripts in – inline, or detached.

Inline (default)

The EC2Launch v2 agent runs scripts one at a time (detach: false). This is the default setting.

Note

When your inline script issues a **reset** or **sysprep** command, it runs immediately and resets the agent. The current task finishes, then the agent shuts down without running any further tasks.

For example, if the task that issues the command would have been followed by a startSsm task (included by default after user data runs), the task doesn't run and the Systems Manager service never starts.

Detached

The EC2Launch v2 agent runs scripts concurrently with other tasks (detach: true).

Note

When your detached script issues a **reset** or **sysprep** command, those commands wait for the agent to finish before they run. Tasks after the executeScript will still run.

Stages: You can run the executeScript task during the PreReady, PostReady, and UserData stages.

Frequency: configurable, see *Inputs*.

Inputs

You can configure runtime parameters as follows:

frequency (string)

(Required) Specify exactly one of the following values:

- once
- always

type (string)

(Required) Specify exactly one of the following values:

- batch
- powershell

arguments (list of strings)

(Optional) A list of string arguments to pass to the shell. This parameter isn't supported for type: batch.

content (string)

(Required) Script content.

runAs (string)

(Required) Specify exactly one of the following values:

- admin
- localSystem

detach (Boolean)

(Optional) The EC2Launch v2 agent defaults to run scripts one at a time (detach: false). To run the script concurrently with other tasks, set the value to true (detach: true).

Note

Script exit codes (including 3010) have no effect when detach is set to true.

Output

All of the tasks write logfile entries to the agent.log file. Additional output from script that the executeScript task runs is stored separately in a dynamically named folder, as follows:

%LocalAppData%\Temp\EC2Launch#####\outputfilename.ext

The exact path to the output files is included in the agent.log file, for example:

```
Program file is created at: C:\Windows\system32\config\systemprofile\AppData\Local\Temp\EC2Launch123456789\UserScript.ps1
Output file is created at: C:\Windows\system32\config\systemprofile\AppData\Local\Temp\EC2Launch123456789\Output.tmp
Error file is created at: C:\Windows\system32\config\systemprofile\AppData\Local\Temp\EC2Launch123456789\Err.tmp
```

Output files for the executeScript task

UserScript.ext

Contains the script that the executeScript task ran. The file extension depends on the type of script you specified in the type parameter for the executeScript task, as follows:

- If the type is batch, then the file extension is .bat.
- If the type is powershell, then the file extension is .ps1.

Output.tmp

Contains runtime output from the script that the executeScript task runs.

Err.tmp

Contains runtime error messages from the script that the executeScript task runs.

Examples

The following examples show how to run an inline script with the executeScript task.

Example 1: Hello world output text file

This example shows an executeScript task that runs a PowerShell script to create a "Hello world" text file on the C: drive.

```
task: executeScript
inputs:
- frequency: always
  type: powershell
  runAs: admin
  content: |-
    New-Item -Path 'C:\PowerShellTest.txt' -ItemType File
    Set-Content 'C:\PowerShellTest.txt' "Hello world"
```

Example 2: Run two scripts

This example shows that the executeScript task can run more than one script, and the script type doesn't necessarily need to match.

The first script (type: powershell) writes a summary of the processes that are currently running on the instance to a text file located on the C: drive.

The second script (batch) writes the system information to the Output .tmp file.

```
task: executeScript
inputs:
- frequency: always
  type: powershell
  content: |
    Get-Process | Out-File -FilePath C:\Process.txt
  runAs: localSystem
- frequency: always
  type: batch
  content: |
    systeminfo
```

Example 3: Idempotent system configuration with reboots

This example shows an executeScript task that runs an idempotent script to perform the following system configuration with a reboot between each step:

- Rename the computer.
- Join the computer to the domain.
- Enable Telnet.

The script ensures that each operation runs one time only. This prevents a reboot loop and makes the script idempotent.

```
task: executeScript
inputs:
- frequency: always
  type: powershell
  runAs: localSystem
  content: |-
    $name = $env:ComputerName
    if ($name -ne $desiredName) {
      Rename-Computer -NewName $desiredName
      exit 3010
    }
    $domain = Get-ADDomain
    if ($domain -ne $desiredDomain)
    {
      Add-Computer -DomainName $desiredDomain
```

```
        exit 3010
    }
$telnet = Get-WindowsFeature -Name Telnet-Client
if (-not $telnet.Installed)
{
    Install-WindowsFeature -Name "Telnet-Client"
    exit 3010
}
```

extendRootPartition

Extends the root volume to use all of the available space on the disk.

Frequency — once

AllowedStages — [Boot]

Inputs — none

Example

```
task: extendRootPartition
```

initializeVolume

Initializes volumes attached to the instance so that they are activated and partitioned. Any volumes that are detected as not empty are not initialized. A volume is considered empty if the first 4 KiB of a volume are empty, or if a volume does not have a [Windows-recognizable drive layout](#). The volume letter field is always applied when this task runs, regardless of whether the drive is already initialized.

Frequency — always

AllowedStages — [PostReady, UserData]

Inputs —

initialize: (string) type of initialization strategy to use; one of all or devices

devices: (list of maps)

device: device identifier used when creating the instance; some examples are xvdb, xvdf, or /dev/nvme0n1

name: (string) drive name to assign

letter: (string) drive letter to assign

partition: (string) partitioning type to use; one of mbr or gpt

Example 1

The following example shows inputs for the InitializeVolume task to set selected volumes to be initialized.

```
task: initializeVolume
inputs:
  initialize: devices
  devices:
  - device: xvdb
    name: MyVolumeOne
    letter: D
```

```
partition: mbr
- device: /dev/nvme0n1
  name: MyVolumeTwo
  letter: E
  partition: gpt
```

Example 2

The following example shows how to initialize EBS volumes that are attached to an instance. This configuration will initialize all empty EBS volumes that are attached to the instance. If a volume is not empty, then it will not be initialized.

```
task: initializeVolume
inputs:
  initialize: all
```

optimizeEna

Optimizes ENA settings based on the current instance type; might reboot the instance.

Frequency — always

AllowedStages — [PostReady, UserData]

Inputs — none

Example

```
task: optimizeEna
```

setAdminAccount

Sets attributes for the default administrator account that is created on the local machine.

Frequency — once

AllowedStages — [PreReady]

Inputs —

name: (string) name of the administrator account

password: (map)

type: (string) strategy to set the password, either as static, random, or doNothing

data: (string) stores data if the type field is static

Example

```
task: setAdminAccount
inputs:
  name: Administrator
  password:
    type: random
```

setDnsSuffix

Adds DNS suffixes to the list of search suffixes. Only suffixes that do not already exist are added to the list.

Frequency — always

AllowedStages — [PreReady]

Inputs —

suffixes: (list of strings) list of one or more valid DNS suffixes; valid substitution variables are \$REGION and \$AZ

Example

```
task: setDnsSuffix
inputs:
  suffixes:
    - $REGION.ec2-utilities.amazonaws.com
```

setHostName

Sets the hostname of the computer to a custom string or, if hostName is not specified, the private IPv4 address.

Frequency — always

AllowedStages — [PostReady, UserData]

Inputs —

hostName: (string) optional host name, which must be formatted as follows.

- Must be 15 characters or less
- Must contain only alphanumeric (a-z, A-Z, 0-9) and hyphen (-) characters.
- Must not consist entirely of numerical characters.

reboot: (boolean) denotes whether a reboot is permitted when the hostname is changed

Example

```
task: setHostName
inputs:
  reboot: true
```

setWallpaper

Creates the `setwallpaper.lnk` shortcut file in the startup folder of each existing user except for `Default User`. This shortcut file runs when the user logs in for the first time after instance boot. It sets up the instance with a custom wallpaper that displays the instance attributes.

The shortcut file path is:

```
$env:SystemDrive/Users/<user>/AppData/Roaming/Microsoft/Windows/Start Menu/Programs/
Startup/setwallpaper.lnk
```

Note

When you remove the `setWallpaper` task, it does not delete this shortcut file. For more information, see [setWallpaper task is not enabled but the wallpaper resets at reboot \(p. 732\)](#).

Stages: You can configure wallpaper during the PreReady, and UserData stages.

Frequency: always

Wallpaper configuration

You can use the following settings to configure your wallpaper.

Inputs

Input parameters that you provide, and attributes that you can set to configure your wallpaper:
attributes (list of strings)

(Optional) You can add one or more of the following attributes to your wallpaper:

- architecture
- availabilityZone
- hostName
- instanceId
- instanceSize
- memory
- network
- privateIpAddress
- publicIpAddress

instanceTags

(Optional) You can use exactly one of the following options for this setting.

- **AllTags** (string) – Add all instance tags to your wallpaper.

```
instanceTags: AllTags
```

- **instanceTags** (list of strings) – Specify a list of instance tag names to add to your wallpaper.
For example:

```
instanceTags:  
- Tag 1  
- Tag 2
```

path (string)

(Required) The filename path of the local .jpg format image file to use for your wallpaper image.

Example

The following example shows wallpaper configuration inputs that set the file path for the wallpaper background image, along with instance tags named Tag_1 and Tag_2, and attributes that include the host name, instance ID, and private and public IP addresses for the instance.

```
task: setWallpaper  
inputs:  
  path: C:\ProgramData\Amazon\EC2Launch\wallpaper\Ec2Wallpaper.jpg  
  attributes:  
    - hostName  
    - instanceId  
    - privateIpAddress  
    - publicIpAddress
```

```
instanceTags:  
- Tag 1  
- Tag 2
```

Note

You must enable tags in metadata to show tags on the wallpaper. For more information about instance tags and metadata, see [Work with instance tags in instance metadata \(p. 2097\)](#).

startSsm

Starts the Systems Manager (SSM) service following Sysprep.

Frequency — always

AllowedStages — [PostReady, UserData]

Inputs — none

Example

```
task: startSsm
```

sysprep

Resets the service state, updates unattend.xml, disables RDP, and runs Sysprep. This task runs only after all other tasks are completed.

Frequency — once

AllowedStages — [UserData]

Inputs —

clean: (boolean) cleans instance logs before running Sysprep

shutdown: (boolean) shuts down the instance after running Sysprep

Example

```
task: sysprep  
inputs:  
  clean: true  
  shutdown: true
```

writeFile

Writes a file to a destination.

Frequency — see *Inputs*

AllowedStages — [PostReady, UserData]

Inputs —

frequency: (string) one of once or always

destination: (string) path to which to write the content

content: (string) text to write to the destination

Example

```
task: writeFile
inputs:
- frequency: once
  destination: C:\Users\Administrator\Desktop\booted.txt
  content: Windows Has Booted
```

EC2Launch v2 exit codes and reboots

You can use EC2Launch v2 to define how exit codes are handled by your scripts. By default, the exit code of the last command that is run in a script is reported as the exit code for the entire script. For example, if a script includes three commands and the first command fails but the following ones succeed, the run status is reported as success because the final command succeeded.

If you want a script to reboot an instance, then you must specify `exit 3010` in your script, even when the reboot is the last step in your script. `exit 3010` instructs EC2Launch v2 to reboot the instance and call the script again until it returns an exit code that is not `3010`, or until the maximum reboot count has been reached. EC2Launch v2 permits a maximum of 5 reboots per task. If you attempt to reboot an instance from a script by using a different mechanism, such as `Restart-Computer`, then the script run status will be inconsistent. For example, it may get stuck in a restart loop or not perform the restart.

If you are using an XML user data format that is compatible with older agents, the user data may run more times than you intend it to. For more information, see [Service runs user data more than once \(p. 731\)](#) in the Troubleshooting section.

EC2Launch v2 and Sysprep

The EC2Launch v2 service runs Sysprep, a Microsoft tool that enables you to create a customized Windows AMI that can be reused. When EC2Launch v2 calls Sysprep, it uses the files in `%ProgramData%\Amazon\EC2Launch` to determine which operations to perform. You can edit these files indirectly using the **EC2Launch settings** dialog box, or directly using a YAML editor or a text editor. However, there are some advanced settings that aren't available in the **EC2Launch settings** dialog box, so you must edit those entries directly.

If you create an AMI from an instance after updating its settings, the new settings are applied to any instance that's launched from the new AMI. For information about creating an AMI, see [Create a custom Windows AMI \(p. 151\)](#).

Troubleshoot EC2Launch v2

This section shows common troubleshooting scenarios for EC2Launch v2, information about viewing Windows event logs, and console log output and messages.

Troubleshooting topics

- [Common troubleshooting scenarios \(p. 730\)](#)
- [Windows event logs \(p. 734\)](#)
- [EC2Launch v2 console log output \(p. 737\)](#)

Common troubleshooting scenarios

This section shows common troubleshooting scenarios and steps for resolution.

Scenarios

- [Service fails to set the wallpaper \(p. 731\)](#)

- [Service fails to run user data \(p. 731\)](#)
- [Service runs a task only one time \(p. 731\)](#)
- [Service fails to run a task \(p. 731\)](#)
- [Service runs user data more than once \(p. 731\)](#)
- [Scheduled tasks from EC2Launch v1 fail to run after migration to EC2Launch v2 \(p. 732\)](#)
- [Service initializes an EBS volume that is not empty \(p. 732\)](#)
- [setWallpaper task is not enabled but the wallpaper resets at reboot \(p. 732\)](#)
- [Service stuck in running status \(p. 733\)](#)
- [Invalid agent-config.yml prevents opening EC2Launch v2 settings dialog box \(p. 733\)](#)
- [task:executeScript should be unique and only invoked once \(p. 734\)](#)

Service fails to set the wallpaper

Resolution

1. Check that %AppData%\Roaming\Microsoft\Windows\Start Menu\Programs\Startup\setwallpaper.lnk exists.
2. Check %ProgramData%\Amazon\EC2Launch\log\agent.log to see if any errors occurred.

Service fails to run user data

Possible cause: Service may have failed before running user data.

Resolution

1. Check %ProgramData%\Amazon\EC2Launch\state\previous-state.json.
2. See if boot, network, preReady, and postReadyLocalData have all been marked as success.
3. If one of the stages failed, check %ProgramData%\Amazon\EC2Launch\log\agent.log for specific errors.

Service runs a task only one time

Resolution

1. Check the frequency of the task.
2. If the service already ran after Sysprep, and the task frequency is set to once, the task will not run again.
3. Set the frequency of the task to always if you want it to run the task every time EC2Launch v2 runs.

Service fails to run a task

Resolution

1. Check the latest entries in %ProgramData%\Amazon\EC2Launch\log\agent.log.
2. If no errors occurred, try running the service manually from "%ProgramFiles%\Amazon\EC2Launch\EC2Launch.exe" run to see if the tasks succeed.

Service runs user data more than once

Resolution

User data is handled differently between EC2Launch v1 and EC2Launch v2. EC2Launch v1 runs user data as a scheduled task on the instance when `persist` is set to true. If `persist` is set to false, the task is not scheduled even when it exits with a reboot or is interrupted while running.

EC2Launch v2 runs user data as an agent task and tracks its run state. If user data issues a computer restart or if user data was interrupted while running, the run state persists as pending and the user data will run again at the next instance boot. If you want to prevent the user data script from running more than once, make the script idempotent.

The following example idempotent script sets the computer name and joins a domain.

```
<powershell>
$name = $env:computername
if ($name -ne $desiredName) {
    Rename-Computer -NewName $desiredName
}
$domain = Get-ADDomain
if ($domain -ne $desiredDomain)
{
    Add-Computer -DomainName $desiredDomain
}
$telnet = Get-WindowsFeature -Name Telnet-Client
if (-not $telnet.Installed)
{
    Install-WindowsFeature -Name "Telnet-Client"
}
</powershell>
<persist>false</persist>
```

Scheduled tasks from EC2Launch v1 fail to run after migration to EC2Launch v2

Resolution

The migration tool does not detect any scheduled tasks linked to EC2Launch v1 scripts; therefore, it does not automatically set up those tasks in EC2Launch v2. To configure these tasks, edit the [agent-config.yml \(p. 716\)](#) file, or use the [EC2Launch v2 settings dialog box \(p. 703\)](#). For example, if an instance has a scheduled task that runs `InitializeDisks.ps1`, then after you run the migration tool, you must specify the volumes you want to initialize in the EC2Launch v2 settings dialog box. See Step 6 of the procedure to [Change settings using the EC2Launch v2 settings dialog box \(p. 703\)](#).

Service initializes an EBS volume that is not empty

Resolution

Before it initializes a volume, EC2Launch v2 attempts to detect whether it is empty. If a volume is not empty, it skips the initialization. Any volumes that are detected as not empty are not initialized. A volume is considered empty if the first 4 KiB of a volume are empty, or if a volume does not have a [Windows-recognizable drive layout](#). A volume that was initialized and formatted on a Linux system does not have a Windows-recognizable drive layout, for example MBR or GPT. Therefore, it will be considered as empty and initialized. If you want to preserve this data, do not rely on EC2Launch v2 empty drive detection. Instead, specify volumes that you would like to initialize in the [EC2Launch v2 settings dialog box \(p. 703\)](#) (see step 6) or in the [agent-config.yml \(p. 725\)](#).

setWallpaper task is not enabled but the wallpaper resets at reboot

The `setWallpaper` task creates the `setwallpaper.lnk` shortcut file in the startup folder of each existing user except for `Default User`. This shortcut file runs when the user logs in for the first time after instance boot. It sets up the instance with a custom wallpaper that displays the instance attributes. Removing the `setWallpaper` task does not delete this shortcut file. You must manually delete this file or delete it using a script.

The shortcut path is:

```
$env:SystemDrive/Users/<user>/AppData/Roaming/Microsoft/Windows/Start Menu/Programs/Startup/setwallpaper.lnk
```

Resolution

Manually delete this file, or delete it using a script.

Example PowerShell script to delete shortcut file

```
foreach ($userDir in (Get-ChildItem "C:\Users" -Force -Directory).FullName)
{
    $startupPath = Join-Path $userDir -ChildPath "AppData\Roaming\Microsoft\Windows\Start Menu\Programs\Startup"
    if (Test-Path $startupPath)
    {
        $wallpaperSetupPath = Join-Path $startupPath -ChildPath "setwallpaper.lnk"
        if (Test-Path $wallpaperSetupPath)
        {
            Remove-Item $wallpaperSetupPath -Force -Confirm:$false
        }
    }
}
```

Service stuck in running status

Description

EC2Launch v2 is blocked, with log messages (agent.log) similar to the following:

```
2022-02-24 08:08:58 Info:
*****
2022-02-24 08:08:58 Info: EC2Launch Service starting
2022-02-24 08:08:58 Info: Windows event custom log exists: Amazon EC2Launch
2022-02-24 08:08:58 Info: ACPI SPCR table not supported. Bailing Out
2022-02-24 08:08:58 Info: Serial port is in use. Waiting for Serial Port...
2022-02-24 08:09:00 Info: ACPI SPCR table not supported. Use default console port.
2022-02-24 08:09:02 Info: ACPI SPCR table not supported. Use default console port.
2022-02-24 08:09:04 Info: ACPI SPCR table not supported. Use default console port.
2022-02-24 08:09:06 Info: ACPI SPCR table not supported. Use default console port.
```

Possible cause

SAC is enabled and using the serial port. For more information, see [Use SAC to troubleshoot your Windows instance](#).

Resolution

Try the following steps to resolve this issue:

- Disable the service that is using the serial port.
- If you want the service to continue to use the serial port, write custom scripts to perform launch agent tasks and invoke them as scheduled tasks.

Invalid agent-config.yml prevents opening EC2Launch v2 settings dialog box

Description

EC2Launch v2 settings attempts to parse the agent-config.yml file before it opens the dialog box. If the YAML configuration file does not follow the supported schema, the dialog box will show the following error:

Unable to parse configuration file agent-config.yml. Review configuration file.
Exiting application.

Resolution

1. Verify that the configuration file follows the [supported schema \(p. 716\)](#).
2. If you want to start from scratch, copy the default configuration file into agent-config.yml. You can use the [example agent-config.yml \(p. 716\)](#) provided in the Task Configuration section.
3. You can also start over by deleting agent-config.yml. EC2Launch v2 settings generates an empty configuration file.

task:executeScript should be unique and only invoked once

Description

A task cannot be repeated in the same stage.

Resolution

Some tasks must be input as an array, such as [executeScript \(p. 722\)](#) and [executeProgram \(p. 720\)](#). For an example of how to write the script as an array, see [executeScript \(p. 722\)](#).

Windows event logs

EC2Launch v2 publishes Windows event logs for important events, such as service starting, Windows is ready, and task success and failure. Event identifiers uniquely identify a particular event. Each event contains stage, task, and level information, and a description. You can set triggers for specific events using the event identifier.

Event IDs provide information about an event and uniquely identify some events. The least significant digit of an event ID indicates the severity of an event.

Event	Least significant digit
Success	. . . 0
Informational	. . . 1
Warning	. . . 2
Error	. . . 3

Service-related events that are generated when the service starts or stops include a single digit event identifier.

Event	Single digit identifier
Success	0
Informational	1
Warning	2
Error	3

The event messages for EC2LaunchService.exe events begin with Service:. The event messages for EC2Launch.exe events do not begin with Service:.

Four digit event IDs include information about the stage, task, and severity of an event.

Topics

- [Event ID format \(p. 735\)](#)
- [Event ID examples \(p. 735\)](#)
- [Windows event log schema \(p. 736\)](#)

Event ID format

The following table shows the format of an EC2Launch v2 event identifier.

3	2 1	0
S	T	L

The letters and numbers in the table represent the following event type and definitions.

Event type	Definition
S (Stage)	<p>0 - Service-level message</p> <p>1 - Boot</p> <p>2 - Network</p> <p>3 - PreReady</p> <p>5 - Windows is Ready</p> <p>6 - PostReady</p> <p>7 - User Data</p>
T (Task)	The tasks represented by the corresponding two values are different for each stage. To view the complete list of events, see Windows Event log schema (p. 736) .
L (Level of the event)	<p>0 - Success</p> <p>1 - Informational</p> <p>2 - Warning</p> <p>3 - Error</p>

Event ID examples

The following are example event IDs.

- 5000 - Windows is ready to use
- 3010 - Activate windows task in PreReady stage was successful

- 6013 - Set wallpaper task in PostReady Local Data stage encountered an error

Windows event log schema

MessageId/Event Id	Event message
. . . 0	Success
. . . 1	Informational
. . . 2	Warning
. . . 3	Error
x	EC2Launch service-level logs
0	EC2Launch service exited successfully
1	EC2Launch service informational logs
2	EC2Launch service warning logs
3	EC2Launch service error logs
10	Replace state.json with previous-state.json
100	Serial Port
200	Sysprep
300	PrimaryNic
400	Metadata
x000	Stage (1 digit), Task (2 digits), Status (1 digit)
1000	Boot
1010	Boot - extend_root_partition
2000	Network
2010	Network - add_routes
3000	PreReady
3010	PreReady - activate_windows
3020	PreReady - install_egpu_manager
3030	PreReady - set_monitor_on
3040	PreReady - set_hibernation
3050	PreReady - set_admin_account
3060	PreReady - set_dns_suffix
3070	PreReady - set_wallpaper

MessagId/Event Id	Event message
3080	PreReady - set_update_schedule
3090	PreReady - output_log
3100	PreReady - enable_open_ssh
5000	Windows is Ready to use
6000	PostReadyLocalData
7000	PostReadyUserData
6010/7010	PostReadyLocal/UserData - set_wallpaper
6020/7020	PostReadyLocal/UserData - set_update_schedule
6030/7030	PostReadyLocal/UserData - set_hostname
6040/7040	PostReadyLocal/UserData - execute_program
6050/7050	PostReadyLocal/UserData - execute_script
6060/7060	PostReadyLocal/UserData - manage_package
6070/7070	PostReadyLocal/UserData - initialize_volume
6080/7080	PostReadyLocal/UserData - write_file
6090/7090	PostReadyLocal/UserData - start_ssm
7100	PostReadyUserData - enable_open_ssh
6110/7110	PostReadyLocal/UserData - enable_jumbo_frames

EC2Launch v2 console log output

This section contains sample console log output for EC2Launch v2 and lists all of the EC2Launch v2 console log error messages to help you to troubleshoot issues.

Outputs

- [EC2Launch v2 console log output \(p. 737\)](#)
- [EC2Launch v2 console log messages \(p. 738\)](#)

EC2Launch v2 console log output

The following is sample console log output for EC2Launch v2.

```

EC2Launch v2 version histories

Version histories

- [EC2Launch v2 version history \(p. 739\)](#)
- [EC2Launch v2 migration tool version history \(p. 742\)](#)

EC2Launch v2 version history

The following table describes the released versions of EC2Launch v2.

Version	Details	Release date
2.0.1521	<ul style="list-style-type: none">• Deprecated the <code>-block</code> flag of the <code>EC2Launch.exe reset</code> and <code>sysprep</code> commands.• Updated <code>EC2Launch.exe</code> to detect and handle the <code>reset</code> and <code>sysprep</code> commands that are used in inline <code>executeScript</code> tasks. Those commands cause the agent to stop running after the <code>executeScript</code> task runs them.• Updated XML userdata scripts to run inline by default.• Enable XML userdata scripts to run detached with the new <code>detach</code> tag. For more details, see User data scripts (p. 853).• Made the following changes to the agent log.<ul style="list-style-type: none">• Updated agent log messages.• Removed <code>executeScript</code> content and output from the agent log.• Removed <code>executeProgram</code> arguments and output from the agent log.• Made the following changes to the console log.<ul style="list-style-type: none">• Added <code>EnableMaprCompatibilityWithWSFC</code> value to the console log.• Added <code>EnableSCSIPersistentReservations</code> value to the console log.	July 3, 2023
2.0.1303	<ul style="list-style-type: none">• Added additional error handling and log lines when adding network routes.• Allowed <code>executeScript</code> and <code>executeProgram</code> tasks in the <code>PreReady</code> stage.• Updated <code>executeProgram</code> task to generate output files similar to the output from the <code>executeScript</code> task. For more information, see executeProgram (p. 720).	May 3, 2023

Version	Details	Release date
	<ul style="list-style-type: none"> Added telemetry to monitor usage of blocking agent commands in XML user data. 	
2.0.1245	<ul style="list-style-type: none"> Improved visibility into crashes by logging crash call stacks in clear text. Added the EventLog service as a startup dependency to fix a crash when the Amazon EC2Launch service starts up faster than the EventLog service. Made XML user data run before PostReady stage from the agent config file (like EC2Launch v1 and EC2Config). Added YAML user data version 1.1 to make user data run before PostReady stage from the agent config file (YAML user data version 1.0 runs after PostReady stage from the agent config file). 	March 8, 2023
2.0.1173	<ul style="list-style-type: none"> Adds an optional feature to display instance tags on wallpaper. For more information, see setWallpaper (p. 727). Adds error handling when the security group for Elastic Graphics is not properly set up. Fixes a timeout when the Instance Metadata Service is not enabled. 	February 6, 2023
2.0.1121	<ul style="list-style-type: none"> Fixes an issue where a 404 error is printed to the wallpaper when no public IPv4 address is assigned. Fixes an issue where the volume's file system is formatted as RAW instead of NTFS when its device's drive letter is set to D. Fixes an issue where NVMe SSD volumes are incorrectly identified as EBS volumes. Fixes an error when activating Windows when IMDS is disabled. 	January 4, 2023
2.0.1082	<ul style="list-style-type: none"> Fixes an issue where the <code>setWallpaper:privateIpAddress</code> field is blank when IMDS is disabled. Fixes an issue with setting the hostname to the private IPv4 address when IMDS is disabled. Fixes an issue with initializing volumes on Windows Server 2012. Fixes an issue with setting jumbo frames. Fixes an error when no SSH key is specified at instance launch. Fixes an error on Windows Server 2012 when Windows does not have a 'Releaseld' registry key. 	December 7, 2022
2.0.1011	<ul style="list-style-type: none"> Fixes logic for finding network adapter when PnPDeviceID is empty. 	November 11, 2022
2.0.1009	<ul style="list-style-type: none"> Uses PCI segment information to select the console port. 	November 8, 2022
2.0.982	<ul style="list-style-type: none"> Adds retry logic to get RDP information. Fixes errors during volume initialization on d2.8xlarge instances. Fixes issue where an incorrect network adapter can be selected after a reboot. Removes false alarm error message when ACPI SPCR is unavailable. 	October 31, 2022

Version	Details	Release date
2.0.863	<ul style="list-style-type: none"> Updates IMDS wait logic to make only IMDSv2 requests. Adds logic to assign drive letter to volumes that are already initialized but not mounted. Prints a more specific error message when key pair type is not supported. Fixes 3010 reboot code bug. Adds check for invalid base64-encoded user data. 	July 6, 2022
2.0.698	<ul style="list-style-type: none"> Fixes typo in log output when executing scripts. 	January 30, 2022
2.0.674	<ul style="list-style-type: none"> Telemetry uploads the enabled/disabled privacy control. Fixes index out of bounds bug. Removes wallpaper shortcuts during sysprep. 	November 15, 2021
2.0.651	<ul style="list-style-type: none"> Adds logic to uninstall legacy agents during EC2Launch v2 installation. Fixes list-volume CLI issue when root volume is not listed as volume 0. 	October 7, 2021
2.0.592	<ul style="list-style-type: none"> Fixes bug to correctly report stage status. Removes false alarm error messages when log files are closed. Adds telemetry. 	August 31, 2021
2.0.548	<ul style="list-style-type: none"> Adds leading zeros for hex IP hostname. Fixes file permissions for enableOpenSsh task. Fixes sysprep command crash. 	August 4, 2021
2.0.470	<ul style="list-style-type: none"> Fixes bug in network stage to wait for DHCP to assign an IP to the instance. Fixes bug with setDnsSuffix when SearchList registry key does not exist. Fixes bug in DNS devolution logic in setDnsSuffix. Adds network routes after intermediate reboots. Allows initializeVolume to re-letter existing volumes. Removes extra information from version subcommand. 	July 20, 2021
2.0.285	<ul style="list-style-type: none"> Adds option to run user scripts in a detached process. Legacy userdata (XML userdata) now runs in a detached process, which is similar behavior to the prior launch agent. Adds CLI flag to the sysprep and reset commands, which allows them to block until the service stops. Restricts the config folder permissions. 	March 8, 2021

Version	Details	Release date
2.0.207	<ul style="list-style-type: none"> • Adds optional hostName field to setHostName task. • Fixes reboot bug. Reboot tasks executeScript and executeProgram will be marked as running. • Adds more return codes to the status command. • Adds bootstrap service to fix startup issue when running on t2.nano instance type. • Fixes clean installation mode to remove files not tracked by installer. 	February 2, 2021
2.0.160	<ul style="list-style-type: none"> • Fixes validate command to detect invalid stage name. • Adds w32tm resync command in addroutes task. • Fixes issue with changing DNS suffix search order. • Adds check conditions to better report invalid user data. 	December 4, 2020
2.0.153	Adds Sysprep functionality in UserData.	November 3, 2020
2.0.146	<ul style="list-style-type: none"> • Fixes issue with RootExtend on non-English AMIs. • Grants users group write permission to log files. • Creates MS Reserved partition for GPT volumes. • Adds list-volumes command and volume dropdown in Amazon EC2Launch settings. • Adds get-agent-config command for printing agent-config.yml file in yaml or json format. • Erases static password if no public key detected. 	October 6, 2020
2.0.124	<ul style="list-style-type: none"> • Adds option to display OS version on wallpaper. • Initializes encrypted EBS volumes. • Adds routes for VPCs with no local DNS name. 	September 10, 2020
2.0.104	<ul style="list-style-type: none"> • Creates DNS suffix search list if it does not exist. • Skips Hibernation if not requested. 	August 12, 2020
2.0.0	Initial release.	June 30, 2020

EC2Launch v2 migration tool version history

The following table describes the released versions of the EC2Launch v2 migration tool.

Version	Details	Release date
1.0.286	Change to use the latest version of the EC2Launch agent: 2.0.1521.	July 14, 2023
1.0.272	Change to use the latest version of the EC2Launch agent: 2.0.1303.	May 3, 2023
1.0.262	Change to use the latest version of the EC2Launch agent: 2.0.1245.	March 9, 2023
1.0.241	Increments the version number of the EC2Launch agent to 2.0.1011.	December 7, 2022
1.0.218	<ul style="list-style-type: none"> • Validates Region value retrieved from instance metadata. 	September 3, 2022

Version	Details	Release date
	<ul style="list-style-type: none"> Fixes migration failure bug in language packs. Increments the version number of the EC2Launch agent to 2.0.863. 	
1.0.162	<ul style="list-style-type: none"> Moves logic to remove legacy agents to the EC2Launch v2 MSI. Increments the version number of the EC2Launch agent to 2.0.698. 	March 18, 2022
1.0.136	Increments the version number of the EC2Launch agent to 2.0.651.	October 13, 2021
1.0.130	Increments the version number of the EC2Launch agent to 2.0.548.	August 5, 2021
1.0.113	Uses IMDSv2 in place of IMDSv1.	June 4, 2021
1.0.101	Increments the version number of the EC2Launch agent to 2.0.285.	March 12, 2021
1.0.86	Increments the version number of the EC2Launch agent to 2.0.207.	February 3, 2021
1.0.76	Increments the version number of the EC2Launch agent to 2.0.160.	December 4, 2020
1.0.69	Increments the version number of the EC2Launch agent to 2.0.153.	November 5, 2020
1.0.65	Increments the version number of the EC2Launch agent to 2.0.146.	October 9, 2020
1.0.60	Increments the version number of the EC2Launch agent to 2.0.124.	September 10, 2020
1.0.54	<ul style="list-style-type: none"> Installs EC2Launch v2 if no agents are installed. Increments the version number of the EC2Launch agent to 2.0.104. Decouples the SSM agent. 	August 12, 2020
1.0.50	Removes NuGet dependency.	August 10, 2020
1.0.0	Initial release.	June 30, 2020

Configure a Windows instance using EC2Launch

EC2Launch is a set of Windows PowerShell scripts that replaced the EC2Config service on Windows Server 2016 and 2019 AMIs. Many of these AMIs are still available. EC2Launch v2 is the latest launch agent for all supported Windows versions, which replaces both EC2Config and EC2Launch. For more information, see [Configure a Windows instance using EC2Launch v2 \(p. 692\)](#).

Contents

- [EC2Launch tasks \(p. 744\)](#)
- [Telemetry \(p. 744\)](#)
- [Install the latest version of EC2Launch \(p. 745\)](#)
- [Verify the EC2Launch version \(p. 746\)](#)

- [EC2Launch directory structure \(p. 746\)](#)
- [Configure EC2Launch \(p. 746\)](#)
- [EC2Launch version history \(p. 750\)](#)

EC2Launch tasks

EC2Launch performs the following tasks by default during the initial instance boot:

- Sets up new wallpaper that renders information about the instance.
- Sets the computer name.
- Sends instance information to the Amazon EC2 console.
- Sends the RDP certificate thumbprint to the EC2 console.
- Sets a random password for the administrator account.
- Adds DNS suffixes.
- Dynamically extends the operating system partition to include any unpartitioned space.
- Executes user data (if specified). For more information about specifying user data, see [Work with instance user data \(p. 885\)](#).
- Sets persistent static routes to reach the metadata service and AWS KMS servers.

Important

If a custom AMI is created from this instance, these routes are captured as part of the OS configuration and any new instances launched from the AMI will retain the same routes, regardless of subnet placement. In order to update the routes, see [Update metadata/KMS routes for Server 2016 and later when launching a custom AMI \(p. 162\)](#).

The following tasks help to maintain backward compatibility with the EC2Config service. You can also configure EC2Launch to perform these tasks during startup:

- Initialize secondary EBS volumes.
- Send Windows Event logs to the EC2 console logs.
- Send the *Windows is ready to use* message to the EC2 console.

For more information about Windows Server 2019, see [Compare Features in Windows Server Versions](#) on Microsoft.com.

Telemetry

Telemetry is additional information that helps AWS to better understand your requirements, diagnose issues, and deliver features to improve your experience with AWS services.

EC2Launch version 1.3.2003498 and later collect telemetry, such as usage metrics and errors. This data is collected from the Amazon EC2 instance on which EC2Launch runs. This includes all Windows AMIs owned by AWS.

The following types of telemetry are collected by EC2Launch:

- **Usage information** — agent commands, install method, and scheduled run frequency.
- **Errors and diagnostic information** — agent installation and run error codes.

Examples of collected data:

```
2021/07/15 21:44:12Z: EC2LaunchTelemetry: IsAgentScheduledPerBoot=true
```

```
2021/07/15 21:44:12Z: EC2LaunchTelemetry: IsUserDataScheduledPerBoot=true
2021/07/15 21:44:12Z: EC2LaunchTelemetry: AgentCommandCode=1
2021/07/15 21:44:12Z: EC2LaunchTelemetry: AgentCommandErrorCode=5
2021/07/15 21:44:12Z: EC2LaunchTelemetry: AgentInstallCode=2
2021/07/15 21:44:12Z: EC2LaunchTelemetry: AgentInstallErrorCode=0
```

Telemetry is enabled by default. You can disable telemetry collection at any time. If telemetry is enabled, EC2Launch sends telemetry data without additional customer notifications.

Your choice to enable or disable telemetry is collected.

You can opt in or out of telemetry collection. Your selection to opt in or out of telemetry is collected to ensure that we adhere to your telemetry option.

Telemetry visibility

When telemetry is enabled, it appears in the Amazon EC2 console output as follows:

```
2021/07/15 21:44:12Z: Telemetry: <Data>
```

Disable telemetry on an instance

To disable telemetry by setting a system environment variable, run the following command as an administrator:

```
setx /M EC2LAUNCH_TELEMETRY 0
```

To disable telemetry during installation, run `install.ps1` as follows:

```
. .\install.ps1 -EnableTelemetry:$false
```

Install the latest version of EC2Launch

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](#).

Use the following procedure to download and install the latest version of EC2Launch on your instances.

To download and install the latest version of EC2Launch

1. If you have already installed and configured EC2Launch on an instance, make a backup of the EC2Launch configuration file. The installation process does not preserve changes in this file. By default, the file is located in the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config` directory.
2. Download [EC2-Windows-Launch.zip](#) to a directory on the instance.
3. Download [install.ps1](#) to the same directory where you downloaded `EC2-Windows-Launch.zip`.
4. Run `install.ps1`
5. If you made a backup of the EC2Launch configuration file, copy it to the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config` directory.

To download and install the latest version of EC2Launch using PowerShell

If you have already installed and configured EC2Launch on an instance, make a backup of the EC2Launch configuration file. The installation process does not preserve changes in this file. By default, the file is located in the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config` directory.

To install the latest version of EC2Launch using PowerShell, run the following commands from a PowerShell window

```
mkdir $env:USERPROFILE\Desktop\EC2Launch
$url = "https://s3.amazonaws.com/ec2-downloads-windows/EC2Launch/latest/EC2-Windows-
Launch.zip"
$downloadZipFile = "$env:USERPROFILE\Desktop\EC2Launch\" + $(Split-Path -Path $url -Leaf)
Invoke-WebRequest -Uri $url -OutFile $downloadZipFile
$url = "https://s3.amazonaws.com/ec2-downloads-windows/EC2Launch/latest/install.ps1"
$downloadZipFile = "$env:USERPROFILE\Desktop\EC2Launch\" + $(Split-Path -Path $url -Leaf)
Invoke-WebRequest -Uri $url -OutFile $downloadZipFile
& $env:USERPROFILE\Desktop\EC2Launch\install.ps1
```

Verify the installation by checking C:\ProgramData\Amazon\EC2-Windows\Launch.

Verify the EC2Launch version

Use the following Windows PowerShell command to verify the installed version of EC2Launch.

```
PS C:\> Test-ModuleManifest -Path "C:\ProgramData\Amazon\EC2-Windows\Launch\Module
\Ec2Launch.psd1" | Select Version
```

EC2Launch directory structure

EC2Launch is installed by default on Windows Server 2016 and later AMIs in the root directory C:\ProgramData\Amazon\EC2-Windows\Launch.

Note

By default, Windows hides files and folders under C:\ProgramData. To view EC2Launch directories and files, you must either type the path in Windows Explorer or change the folder properties to show hidden files and folders.

The Launch directory contains the following subdirectories.

- Scripts — Contains the PowerShell scripts that make up EC2Launch.
- Module — Contains the module for building scripts related to Amazon EC2.
- Config — Contains script configuration files that you can customize.
- Sysprep — Contains Sysprep resources.
- Settings — Contains an application for the Sysprep graphical user interface.
- Library — Contains shared libraries for EC2 launch agents.
- Logs — Contains log files generated by scripts.

All EC2Launch directories inherit their permissions from C:\ProgramData, with the exception of the following:

- C:\ProgramData\Amazon\EC2-Windows\Launch\Module\Scripts — This folder inherits all initial permissions from C:\ProgramData when it is created, but removes access for normal users to CreateFiles in the directory.

Configure EC2Launch

After your instance has been initialized the first time, you can configure EC2Launch to run again and perform different start-up tasks.

Tasks

- [Configure initialization tasks \(p. 747\)](#)
- [Schedule EC2Launch to run on every boot \(p. 748\)](#)
- [Initialize drives and map drive letters \(p. 748\)](#)
- [Send Windows event logs to the EC2 console \(p. 749\)](#)
- [Send Windows is ready message after a successful boot \(p. 749\)](#)

Configure initialization tasks

Specify settings in the `LaunchConfig.json` file to enable or disable the following initialization tasks:

- Set the computer name.
- Set the monitor to always stay on.
- Set up new wallpaper.
- Add DNS suffix list.
- Extend the boot volume size.
- Set the administrator password.

To configure initialization settings

1. On the instance to configure, open the following file in a text editor: `C:\ProgramData\Amazon\EC2-Windows\Launch\Config\LaunchConfig.json`.
2. Update the following settings as needed and save your changes. Provide a password in `adminPassword` only if `adminPasswordType` is `Specify`.

```
{  
    "setComputerName": false,  
    "setMonitorAlwaysOn": true,  
    "setWallpaper": true,  
    "addDnsSuffixList": true,  
    "extendBootVolumeSize": true,  
    "handleUserData": true,  
    "adminPasswordType": "Random | Specify | DoNothing",  
    "adminPassword": "password that adheres to your security policy (optional)"  
}
```

The password types are defined as follows:

Random

EC2Launch generates a password and encrypts it using the user's key. The system disables this setting after the instance is launched so that this password persists if the instance is rebooted or stopped and started.

Specify

EC2Launch uses the password you specify in `adminPassword`. If the password does not meet the system requirements, EC2Launch generates a random password instead. The password is stored in `LaunchConfig.json` as clear text and is deleted after Sysprep sets the administrator password. EC2Launch encrypts the password using the user's key.

DoNothing

EC2Launch uses the password you specify in the `unattend.xml` file. If you don't specify a password in `unattend.xml`, the administrator account is disabled.

3. In Windows PowerShell, run the following command to schedule the script to run as a Windows Scheduled Task. The script runs one time during the next boot and then disables these tasks from running again.

```
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -  
Schedule
```

Schedule EC2Launch to run on every boot

You can schedule EC2Launch to run on every boot instead of only the initial boot.

To enable EC2Launch to run on every boot:

1. Open Windows PowerShell and run the following command:

```
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -  
SchedulePerBoot
```

2. Or, run the executable with the following command:

```
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Settings\Ec2LaunchSettings.exe
```

Then select Run EC2Launch on every boot. You can specify that your EC2 instance Shutdown without Sysprep or Shutdown with Sysprep.

Note

When you enable EC2Launch to run on every boot, the following happens the next time EC2Launch runs:

- If AdminPasswordType is still set to Random, EC2Launch will generate a new password at the next boot. After that boot, AdminPasswordType is automatically set to DoNothing to prevent EC2Launch from generating new passwords on subsequent boots. To prevent EC2Launch from generating a new password on the first boot, manually set AdminPasswordType to DoNothing before you reboot.
- HandleUserData will be set back to false unless the user data has persist set to true. For more information about user data scripts, see [User Data Scripts](#) in the Amazon EC2 User Guide.

Initialize drives and map drive letters

Specify settings in the DriveLetterMappingConfig.json file to map drive letters to volumes on your EC2 instance. The script initializes drives that are not already initialized and partitioned. For more information about getting volume details in Windows, see [Get-Volume](#) in the Microsoft documentation.

To map drive letters to volumes

1. Open the C:\ProgramData\Amazon\EC2-Windows\Launch\Config\DriveLetterMappingConfig.json file in a text editor.
2. Specify the following volume settings and save your changes:

```
{  
  "driveLetterMapping": [  
    {  
      "volumeName": "sample volume",  
    }]
```

```
        "driveLetter": "H"  
    }  
}  
}
```

3. Open Windows PowerShell and use the following command to run the EC2Launch script that initializes the disks:

```
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeDisks.ps1
```

To initialize the disks each time the instance boots, add the `-Schedule` flag as follows:

```
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeDisks.ps1 -Schedule
```

Send Windows event logs to the EC2 console

Specify settings in the `EventLogConfig.json` file to send Windows Event logs to EC2 console logs.

To configure settings to send Windows Event logs

1. On the instance, open the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config\EventLogConfig.json` file in a text editor.
2. Configure the following log settings and save your changes:

```
{  
    "events": [  
        {  
            "logName": "System",  
            "source": "An event source (optional)",  
            "level": "Error | Warning | Information",  
            "numEntries": 3  
        }  
    ]  
}
```

3. In Windows PowerShell, run the following command so that the system schedules the script to run as a Windows Scheduled Task each time the instance boots.

```
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\SendEventLogs.ps1 -Schedule
```

The logs can take three minutes or more to appear in the EC2 console logs.

Send Windows is ready message after a successful boot

The EC2Config service sent the "Windows is ready" message to the EC2 console after every boot. EC2Launch sends this message only after the initial boot. For backwards compatibility with the EC2Config service, you can schedule EC2Launch to send this message after every boot. On the instance, open Windows PowerShell and run the following command. The system schedules the script to run as a Windows Scheduled Task.

```
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\SendWindowsIsReady.ps1 -Schedule
```

EC2Launch version history

Windows AMIs starting with Windows Server 2016 include a set of Windows Powershell scripts called EC2Launch. EC2Launch performs tasks during the initial instance boot. For information about the EC2Launch versions included in the Windows AMIs, see [AWS Windows AMIs \(p. 41\)](#).

To download and install the latest version of EC2Launch, see [Install the latest version of EC2Launch \(p. 745\)](#).

The following table describes the released versions of EC2Launch. Note that the version format changed after version 1.3.610.

Version	Details	Release date
1.3.2004256	<ul style="list-style-type: none"> Added EnableSCSIPersistentReservations value to console log. Added retry capability for Get-ConsolePort. 	7 July 2023
1.3.2004052	<ul style="list-style-type: none"> Fixed an error that occurred when no SSH key is specified at instance launch. Updated to retry starting the AmazonSSMAgent Windows service on failure. Updated to fail SysprepInstance.ps1 if BeforeSysprep.cmd fails with a non-zero exit code. 	8 March 2023
1.3.2003975	<ul style="list-style-type: none"> Fixed issue impacting Packer AMI builds where SysprepInstance.ps1 returns a \$LastErrorCode of 1. 	24 December 2022
1.3.2003961	<ul style="list-style-type: none"> Fixed issue where explicitly specified administrator passwords are overwritten with a random password on fast-launched instances. Fixed issue where SSM Agent fails to start on smaller instance types. Fixed an issue where the instance console log contains RDPCERTIFICATE-THUMBPRINT: 00000000000000000000 instead of a valid RDP certificate thumbprint value. 	6 December 2022
1.3.2003923	<ul style="list-style-type: none"> Fixes logic for finding network adapter when PnPDeviceID is empty. 	9 November 2022
1.3.2003919	<ul style="list-style-type: none"> Updated Get-ConsolePort to use PCI segment information. Fixed issue where an incorrect network adapter can be selected after reboot. Fixed start-SSM-Agent timeout logic. Fixed backwards compatibility for Send-AdminCredentials function alias. 	8 November 2022
1.3.2003857	<ul style="list-style-type: none"> Prioritizes adapters with a default gateway when the primary network adapter is selected. Extended in-memory password encryption. 	3 October 2022
1.3.2003824	<ul style="list-style-type: none"> Fixed error during setComputerName. Added logic to skip Windows activation when a BYOL billing code is detected. Added in-memory password encryption. 	30 August 2022

Version	Details	Release date
	<ul style="list-style-type: none"> Fixed error during volume initialization on m6id.4xlarge. 	
1.3.2003691	<ul style="list-style-type: none"> Updated IMDS wait logic to make only IMDSv2 requests. Fixed bug impacting eGPU installation. 	21 June 2022
1.3.2003639	<ul style="list-style-type: none"> Added network-adapter wait logic to prevent use before initialization. Fixed minor issues. 	10 May 2022
1.3.2003498	<ul style="list-style-type: none"> Added telemetry. Added shortcut to Settings UI. Formatted PowerShell scripts. Fixed issue with shutdown occurring before BeforeSysprep.cmd completes. 	31 January 2022
1.3.2003411	Changed password generation logic to exclude passwords with low complexity.	04 August 2021
1.3.2003364	Updated Install-EgpuManager with IMDSv2 support.	07 June 2021
1.3.2003312	<ul style="list-style-type: none"> Added log lines before and after setMonitorAlwaysOn setting. Added AWS Nitro Enclaves package version to console log. 	04 May 2021
1.3.2003284	Improved permission model by updating location for storing user data to LocalAppData.	23 March 2021
1.3.2003236	<ul style="list-style-type: none"> Updated method for setting user password in Set-AdminAccount and Randomize-LocalAdminPassword. FixedInitializeDisks to check whether disk is set to read only before setting it to writable. 	11 February 2021
1.3.2003210	Localization fix for install.ps1.	7 January 2021
1.3.2003205	Security fix for install.ps1 to update permissions on %ProgramData%AmazonEC2-WindowsLaunchModuleScripts directory.	28 December 2020
1.3.2003189	Added w32tm resync after adding routes.	4 December 2020
1.3.2003155	Updated instance type information.	25 August 2020
1.3.2003150	Added OsCurrentBuild and OsReleaseId to console output .	22 April 2020
1.3.2003040	Fixed IMDS version 1 fallback logic.	7 April 2020
1.3.2002730	Added support for IMDS V2.	3 March 2020
1.3.2002240	Fixed minor issues.	31 October 2019
1.3.2001660	Fixed automatic login issue for users without password after first time executing Sysprep.	2 July 2019
1.3.2001360	Fixed minor issues.	27 March 2019

Version	Details	Release date
1.3.2001220	All PowerShell scripts signed.	28 February 2019
1.3.2001200	Fixed issue with InitializeDisks.ps1 where running the script on a node in a Windows Server Failover Cluster would format drives on remote nodes whose drive letter matched the local drive letter.	27 February 2019
1.3.2001160	Fixed missing wallpaper in Windows 2019.	22 February 2019
1.3.2001040	<ul style="list-style-type: none"> Added plugin for setting the monitor to never turn off to fix ACPI issues. SQL Server edition and version written to console. 	21 January 2019
1.3.2000930	Fix for adding routes to metadata on ipv6-enabled ENIs.	2 January 2019
1.3.2000760	<ul style="list-style-type: none"> Added default configuration for RSS and Receive Queue settings for ENA devices. Disabled hibernation during Sysprep. 	5 December 2018
1.3.2000630	<ul style="list-style-type: none"> Added route 169.254.169.253/32 for DNS server. Added filter of setting Admin user. Improvements made to instance hibernation. Added option to schedule EC2Launch to run on every boot. 	9 November 2018
1.3.2000430.0	<ul style="list-style-type: none"> Added route 169.254.169.123/32 to AMZN time service. Added route 169.254.169.249/32 to GRID license service. Added timeout of 25 seconds when attempting to start Systems Manager. 	19 September 2018
1.3.200039.0	<ul style="list-style-type: none"> Fixed improper drive lettering for EBS NVME volumes. Added additional logging for NVME driver versions. 	15 August 2018
1.3.2000080	Fixed minor issues.	
1.3.610	Fixed issue with redirecting output and errors to files from user data.	
1.3.590	<ul style="list-style-type: none"> Added missing instances types in the wallpaper. Fixed an issue with drive letter mapping and disk installation. 	
1.3.580	<ul style="list-style-type: none"> Fixed Get-Metadata to use the default system proxy settings for web requests. Added a special case for NVMe in disk initialization. Fixed minor issues. 	
1.3.550	Added a -NoShutdown option to enable Sysprep with no shutdown.	
1.3.540	Fixed minor issues.	
1.3.530	Fixed minor issues.	
1.3.521	Fixed minor issues.	

Version	Details	Release date
1.3.0	<ul style="list-style-type: none"> Fixed a hexadecimal length issue for computer name change. Fixed a possible reboot loop for computer name change. Fixed an issue in wallpaper setup. 	
1.2.0	<ul style="list-style-type: none"> Update to display information about installed operating system (OS) in EC2 system log. Update to display EC2Launch and SSM Agent version in EC2 system log. Fixed minor issues. 	
1.1.2	<ul style="list-style-type: none"> Update to display ENA driver information in EC2 system log. Update to exclude Hyper-V from primary NIC filter logic. Added AWS KMS server and port into registry key for KMS activation. Improved wallpaper setup for multiple users. Update to clear routes from persistent store. Update to remove the z from availability zone in DNS suffix list. Update to address an issue with the <runAsLocalSystem> tag in user data. 	
1.1.1	Initial release.	

Configure a Windows instance using the EC2Config service

The latest launch service for Windows Server 2022 is [EC2Launch v2 \(p. 692\)](#), which replaces both EC2Config and EC2Launch.

Windows AMIs for Windows Server 2012 R2 and earlier include an optional service, the EC2Config service (EC2Config.exe). EC2Config starts when the instance boots and performs tasks during startup and each time you stop or start the instance. EC2Config can also perform tasks on demand. Some of these tasks are automatically enabled, while others must be enabled manually. Although optional, this service provides access to advanced features that aren't otherwise available. This service runs in the LocalSystem account.

Note

EC2Launch replaced EC2Config on Windows AMIs for Windows Server 2016 and 2019. For more information, see [Configure a Windows instance using EC2Launch \(p. 743\)](#). The latest launch service for all supported Windows Server versions is [EC2Launch v2 \(p. 692\)](#), which replaces both EC2Config and EC2Launch.

EC2Config uses settings files to control its operation. You can update these settings files using either a graphical tool or by directly editing XML files. The service binaries and additional files are contained in the %ProgramFiles%\Amazon\EC2ConfigService directory.

Contents

- [EC2Config tasks \(p. 754\)](#)
- [Install the latest version of EC2Config \(p. 755\)](#)
- [Stop, restart, delete, or uninstall EC2Config \(p. 756\)](#)
- [EC2Config and AWS Systems Manager \(p. 757\)](#)

- [EC2Config and Sysprep \(p. 757\)](#)
- [EC2 service properties \(p. 757\)](#)
- [EC2Config settings files \(p. 760\)](#)
- [Configure proxy settings for the EC2Config service \(p. 764\)](#)
- [EC2Config version history \(p. 766\)](#)
- [Troubleshoot issues with the EC2Config service \(p. 778\)](#)

EC2Config tasks

EC2Config runs initial startup tasks when the instance is first started and then disables them. To run these tasks again, you must explicitly enable them prior to shutting down the instance, or by running Sysprep manually. These tasks are as follows:

- Set a random, encrypted password for the administrator account.
- Generate and install the host certificate used for Remote Desktop Connection.
- Dynamically extend the operating system partition to include any unpartitioned space.
- Execute the specified user data (and Cloud-Init, if it's installed). For more information about specifying user data, see [Work with instance user data \(p. 885\)](#).

EC2Config performs the following tasks every time the instance starts:

- Change the host name to match the private IP address in Hex notation (this task is disabled by default and must be enabled in order to run at instance start).
- Configure the key management server (AWS KMS), check for Windows activation status, and activate Windows as necessary.
- Mount all Amazon EBS volumes and instance store volumes, and map volume names to drive letters.
- Write event log entries to the console to help with troubleshooting (this task is disabled by default and must be enabled in order to run at instance start).
- Write to the console that Windows is ready.
- Add a custom route to the primary network adapter to enable the following IP addresses when a single NIC or multiple NICs are attached: 169.254.169.250, 169.254.169.251, and 169.254.169.254. These addresses are used by Windows Activation and when you access instance metadata.

Note

If the Windows OS is configured to use IPv4, these IPv4 link-local addresses can be used. If the Windows OS has the IPv4 network protocol stack disabled and uses IPv6 instead, add [fd00:ec2::240] in place of 169.254.169.250 and 169.254.169.251. Then add [fd00:ec2::254] in place of 169.254.169.254.

EC2Config performs the following task every time a user logs in:

- Display wallpaper information to the desktop background.

While the instance is running, you can request that EC2Config perform the following task on demand:

- Run Sysprep and shut down the instance so that you can create an AMI from it. For more information, see [Create a standardized Amazon Machine Image \(AMI\) using Sysprep \(p. 154\)](#).

Install the latest version of EC2Config

By default, the EC2Config service is included in AMIs prior to Windows Server 2016. When the EC2Config service is updated, new Windows AMIs from AWS include the latest version of the service. However, you need to update your own Windows AMIs and instances with the latest version of EC2Config.

Note

EC2Launch replaces EC2Config on Windows Server 2016 and 2019. For more information, see [Configure a Windows instance using EC2Launch \(p. 743\)](#). The latest launch service for all supported Windows Server versions is [EC2Launch v2 \(p. 692\)](#), which replaces both EC2Config and EC2Launch.

For information about how to receive notifications for EC2Config updates, see [Subscribe to EC2Config service notifications \(p. 778\)](#). For information about the changes in each version, see the [EC2Config version history \(p. 766\)](#).

Before you begin

- Verify that you have .NET framework 3.5 SP1 or greater.
- By default, Setup replaces your settings files with default settings files during installation and restarts the EC2Config service when the installation is completed. If you changed EC2Config service settings, copy the config.xml file from the %Program Files%\Amazon\Ec2ConfigService\Settings directory. After you update the EC2Config service, you can restore this file to retain your configuration changes.
- If your version of EC2Config is earlier than version 2.1.19 and you are installing version 2.2.12 or earlier, you must first install version 2.1.19. To install version 2.1.19, download [EC2Install_2.1.19.zip](#), unzip the file, and then run EC2Install.exe.

Note

If your version of EC2Config is earlier than version 2.1.19 and you are installing version 2.3.313 or later, you can install it directly without installing version 2.1.19 first.

Verify the EC2Config version

Use the following procedure to verify the version of EC2Config that is installed on your instances.

To verify the installed version of EC2Config

1. Launch an instance from your AMI and connect to it.
2. In Control Panel, select **Programs and Features**.
3. In the list of installed programs, look for Ec2ConfigService. Its version number appears in the **Version** column.

Update EC2Config

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](#).

Use the following procedure to download and install the latest version of EC2Config on your instances.

To download and install the latest version of EC2Config

1. Download and unzip the [EC2Config installer](#).

2. Run EC2Install.exe. For a complete list of options, run EC2Install with the /? option. By default, setup displays prompts. To run the command with no prompts, use the /quiet option.

Important

To keep the custom settings from the config.xml file that you saved, run EC2Install with the /norestart option, restore your settings, and then restart the EC2Config service manually.

3. If you are running EC2Config version 4.0 or later, you must restart SSM Agent on the instance from the Microsoft Services snap-in.

Note

The updated EC2Config version information will not appear in the instance System Log or Trusted Advisor check until you reboot or stop and start your instance.

To download and install the latest version of EC2Config using PowerShell

To download, unzip, and install the latest version of EC2Config using PowerShell, run the following commands from a PowerShell window:

```
$Url = "https://s3.amazonaws.com/ec2-downloads-windows/EC2Config/EC2Install.zip"
$DownloadZipFile = "$env:USERPROFILE\Desktop\" + $(Split-Path -Path $Url -Leaf)
$ExtractPath = "$env:USERPROFILE\Desktop\"
Invoke-WebRequest -Uri $Url -OutFile $DownloadZipFile
$ExtractShell = New-Object -ComObject Shell.Application
$ExtractFiles = $ExtractShell.Namespace($DownloadZipFile).Items()
$ExtractShell.NameSpace($ExtractPath).CopyHere($ExtractFiles)
Start-Process $ExtractPath
Start-Process `
    -FilePath $env:USERPROFILE\Desktop\EC2Install.exe `
    -ArgumentList "/S"
```

Verify the installation by checking C:\Program Files\Amazon\ for the Ec2ConfigService directory.

Stop, restart, delete, or uninstall EC2Config

You can manage the EC2Config service just as you would any other service.

To apply updated settings to your instance, you can stop and restart the service. If you're manually installing EC2Config, you must stop the service first.

To stop the EC2Config service

1. Launch and connect to your Windows instance.
2. On the **Start** menu, point to **Administrative Tools**, and then click **Services**.
3. In the list of services, right-click **EC2Config**, and select **Stop**.

To restart the EC2Config service

1. Launch and connect to your Windows instance.
2. On the **Start** menu, point to **Administrative Tools**, and then click **Services**.
3. In the list of services, right-click **EC2Config**, and select **Restart**.

If you don't need to update the configuration settings, create your own AMI, or use AWS Systems Manager, you can delete and uninstall the service. Deleting a service removes its registry subkey. Uninstalling a service removes the files, the registry subkey, and any shortcuts to the service.

To delete the EC2Config service

1. Start a command prompt window.
2. Run the following command:

```
sc delete ec2config
```

To uninstall EC2Config

1. Launch and connect to your Windows instance.
2. On the **Start** menu, click **Control Panel**.
3. Double-click **Programs and Features**.
4. On the list of programs, select **EC2ConfigService**, and click **Uninstall**.

EC2Config and AWS Systems Manager

The EC2Config service processes Systems Manager requests on instances created from AMIs for versions of Windows Server prior to Windows Server 2016 that were published before November 2016.

Instances created from AMIs for versions of Windows Server prior to Windows Server 2016 that were published after November 2016 include the EC2Config service and SSM Agent. EC2Config performs all of the tasks described earlier, and SSM Agent processes requests for Systems Manager capabilities like Run Command and State Manager.

You can use Run Command to upgrade your existing instances to use to the latest version of the EC2Config service and SSM Agent. For more information, see [Update SSM Agent by using Run Command](#) in the *AWS Systems Manager User Guide*.

EC2Config and Sysprep

The EC2Config service runs Sysprep, a Microsoft tool that enables you to create a customized Windows AMI that can be reused. When EC2Config calls Sysprep, it uses the files in %ProgramFiles%\Amazon\EC2ConfigService\Settings to determine which operations to perform. You can edit these files indirectly using the **EC2 Service Properties** dialog box, or directly using an XML editor or a text editor. However, there are some advanced settings that aren't available in the **Ec2 Service Properties** dialog box, so you must edit those entries directly.

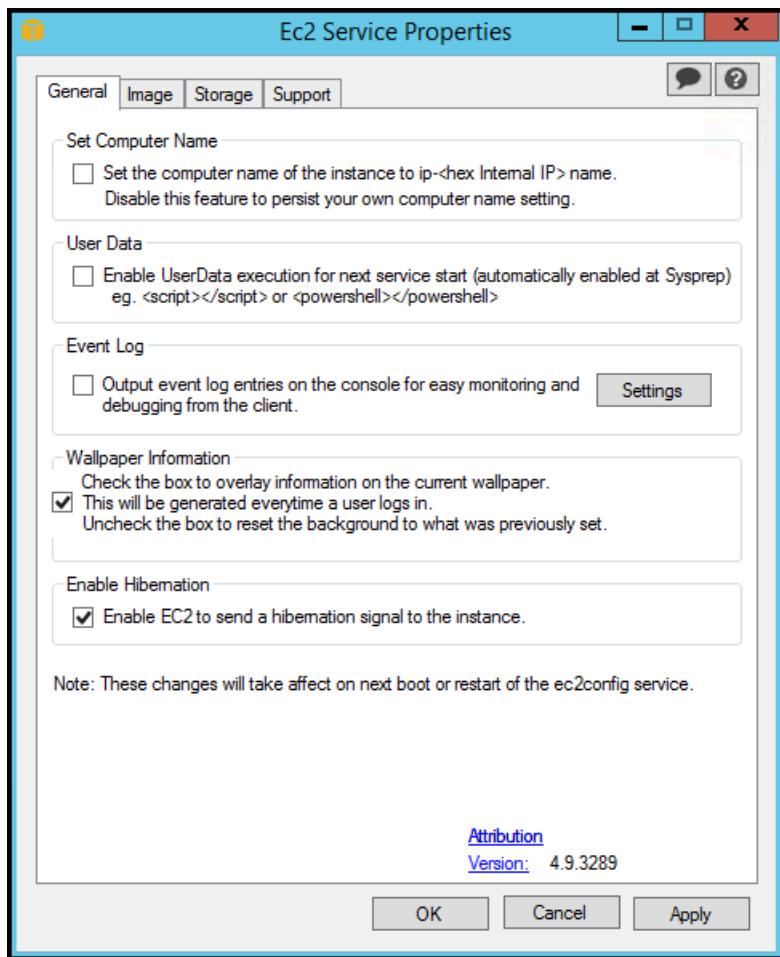

If you create an AMI from an instance after updating its settings, the new settings are applied to any instance that's launched from the new AMI. For information about creating an AMI, see [Create a custom Windows AMI \(p. 151\)](#).

EC2 service properties

The following procedure describes how to use the **Ec2 Service Properties** dialog box to enable or disable settings.

To change settings using the Ec2 Service Properties dialog box

1. Launch and connect to your Windows instance.
2. From the **Start** menu, click **All Programs**, and then click **EC2ConfigService Settings**.

3. On the **General** tab of the **EC2 Service Properties** dialog box, you can enable or disable the following settings.

Set Computer Name

If this setting is enabled (it is disabled by default), the host name is compared to the current internal IP address at each boot; if the host name and internal IP address do not match, the host name is reset to contain the internal IP address and then the system reboots to pick up the new host name. To set your own host name, or to prevent your existing host name from being modified, do not enable this setting.

User Data

User data execution enables you to specify scripts in the instance metadata. By default, these scripts are run during the initial launch. You can also configure them to run the next time you reboot or start the instance, or every time you reboot or start the instance.

If you have a large script, we recommend that you use user data to download the script, and then run it.

For more information, see [User data execution \(p. 856\)](#).

Event Log

Use this setting to display event log entries on the console during boot for easy monitoring and debugging.

Click **Settings** to specify filters for the log entries sent to the console. The default filter sends the three most recent error entries from the system event log to the console.

Wallpaper Information

Use this setting to display system information on the desktop background. The following is an example of the information displayed on the desktop background.

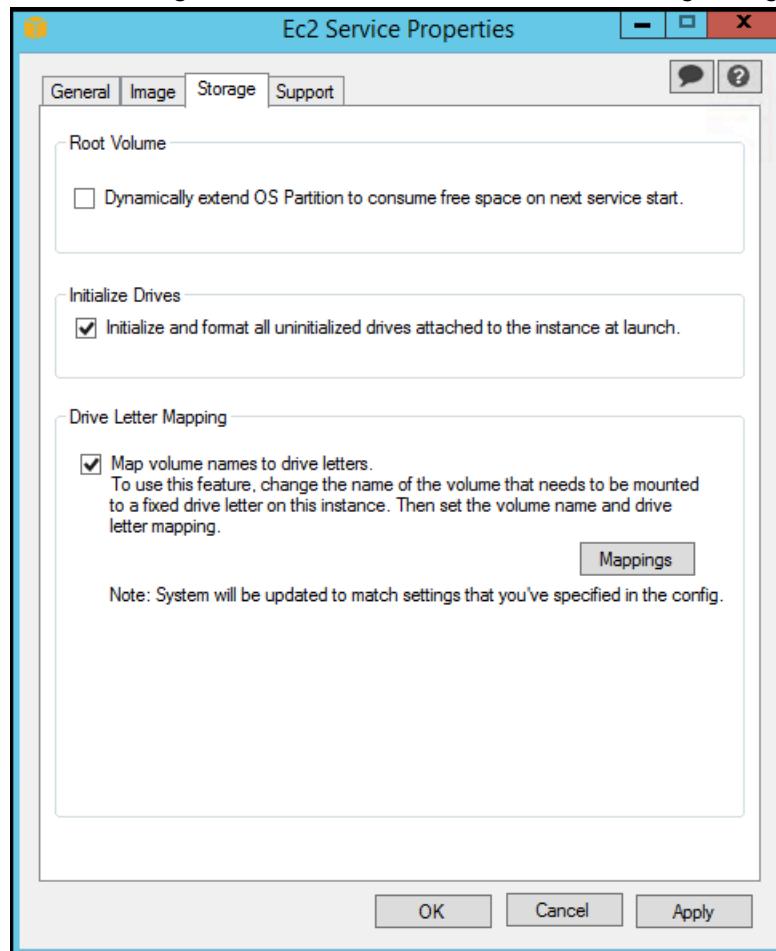

```
Hostname      : WIN-U0RFOJCTPUU
Instance ID   : i-d583f76a
Public IP Address : 54.208.43.227
Private IP Address : 172.31.42.195
Availability Zone : us-east-1b
Instance Size   : t2.micro
Architecture    : AMD64
```

The information displayed on the desktop background is controlled by the settings file EC2ConfigService\Settings\WallpaperSettings.xml.

Enable Hibernation

Use this setting to allow EC2 to signal the operating system to perform hibernation.

4. Click the **Storage** tab. You can enable or disable the following settings.

Root Volume

This setting dynamically extends Disk 0/Volume 0 to include any unpartitioned space. This can be useful when the instance is booted from a root device volume that has a custom size.

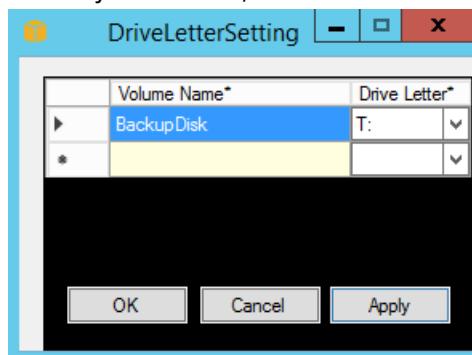

Initialize Drives

This setting formats and mounts all volumes attached to the instance during start.

Drive Letter Mapping

The system maps the volumes attached to an instance to drive letters. For Amazon EBS volumes, the default is to assign drive letters going from D: to Z:. For instance store volumes, the default depends on the driver. AWS PV drivers and Citrix PV drivers assign instance store volumes drive letters going from Z: to A:. Red Hat drivers assign instance store volumes drive letters going from D: to Z:.

To choose the drive letters for your volumes, click **Mappings**. In the **DriveLetterSetting** dialog box, specify the **Volume Name** and **Drive Letter** values for each volume, click **Apply**, and then click **OK**. We recommend that you select drive letters that avoid conflicts with drive letters that are likely to be in use, such as drive letters in the middle of the alphabet.

After you specify a drive letter mapping and attach a volume with same label as one of the volume names that you specified, EC2Config automatically assigns your specified drive letter to that volume. However, the drive letter mapping fails if the drive letter is already in use. Note that EC2Config doesn't change the drive letters of volumes that were already mounted when you specified the drive letter mapping.

5. To save your settings and continue working on them later, click **OK** to close the **EC2 Service Properties** dialog box. If you have finished customizing your instance and want to create an AMI from that instance, see [Create a standardized Amazon Machine Image \(AMI\) using Sysprep \(p. 154\)](#).

EC2Config settings files

The settings files control the operation of the EC2Config service. These files are located in the C:\\Program Files\\Amazon\\Ec2ConfigService\\Settings directory:

- ActivationSettings.xml—Controls product activation using a key management server (AWS KMS).
- AWS.EC2.Windows.CloudWatch.json—Controls which performance counters to send to CloudWatch and which logs to send to CloudWatch Logs.
- BundleConfig.xml—Controls how EC2Config prepares an instance store-backed instance for AMI creation.
- Config.xml—Controls the primary settings.
- DriveLetterConfig.xml—Controls drive letter mappings.

- `EventLogConfig.xml`—Controls the event log information that's displayed on the console while the instance is booting.
- `WallpaperSettings.xml`—Controls the information that's displayed on the desktop background.

ActivationSettings.xml

This file contains settings that control product activation. When Windows boots, the EC2Config service checks whether Windows is already activated. If Windows is not already activated, it attempts to activate Windows by searching for the specified AWS KMS server.

- `SetAutodiscover`—Indicates whether to detect a AWS KMS automatically.
- `TargetKMSServer`—Stores the private IP address of a AWS KMS. The AWS KMS must be in the same Region as your instance.
- `DiscoverFromZone`—Discovers the AWS KMS server from the specified DNS zone.
- `ReadFromUserData`—Gets the AWS KMS server from UserData.
- `LegacySearchZones`—Discovers the AWS KMS server from the specified DNS zone.
- `DoActivate`—Attempts activation using the specified settings in the section. This value can be `true` or `false`.
- `LogResultToConsole`—Displays the result to the console.

BundleConfig.xml

This file contains settings that control how EC2Config prepares an instance for AMI creation.

- `AutoSysprep`—Indicates whether to use Sysprep automatically. Change the value to `Yes` to use Sysprep.
- `SetRDPCertificate`—Sets a self-signed certificate to the Remote Desktop server. This enables you to securely RDP into the instances. Change the value to `Yes` if the new instances should have the certificate.

This setting is not used with Windows Server 2008 or Windows Server 2012 instances because they can generate their own certificates.

- `SetPasswordAfterSysprep`—Sets a random password on a newly launched instance, encrypts it with the user launch key, and outputs the encrypted password to the console. Change the value of this setting to `No` if the new instances should not be set to a random encrypted password.

Config.xml

Plug-ins

- `Ec2SetPassword`—Generates a random encrypted password each time you launch an instance. This feature is disabled by default after the first launch so that reboots of this instance don't change a password set by the user. Change this setting to `Enabled` to continue to generate passwords each time you launch an instance.

This setting is important if you are planning to create an AMI from your instance.

- `Ec2SetComputerName`—Sets the host name of the instance to a unique name based on the IP address of the instance and reboots the instance. To set your own host name, or prevent your existing host name from being modified, you must disable this setting.
- `Ec2InitializeDrives`—Initializes and formats all volumes during startup. This feature is enabled by default.

- **Ec2EventLog**—Displays event log entries in the console. By default, the three most recent error entries from the system event log are displayed. To specify the event log entries to display, edit the EventLogConfig.xml file located in the EC2ConfigService\Settings directory. For information about the settings in this file, see [Eventlog Key](#) in the MSDN Library.
- **Ec2ConfigureRDP**—Sets up a self-signed certificate on the instance, so users can securely access the instance using Remote Desktop. This feature is disabled on Windows Server 2008 and Windows Server 2012 instances because they can generate their own certificates.
- **Ec2OutputRDPCert**—Displays the Remote Desktop certificate information to the console so that the user can verify it against the thumbprint.
- **Ec2SetDriveLetter**—Sets the drive letters of the mounted volumes based on user-defined settings. By default, when an Amazon EBS volume is attached to an instance, it can be mounted using the drive letter on the instance. To specify your drive letter mappings, edit the DriveLetterConfig.xml file located in the EC2ConfigService\Settings directory.
- **Ec2WindowsActivate**—The plug-in handles Windows activation. It checks to see if Windows is activated. If not, it updates the AWS KMS client settings, and then activates Windows.

To modify the AWS KMS settings, edit the ActivationSettings.xml file located in the EC2ConfigService\Settings directory.

- **Ec2DynamicBootVolumeSize**—Extends Disk 0/Volume 0 to include any unpartitioned space.
- **Ec2HandleUserData**—Creates and runs scripts created by the user on the first launch of an instance after Sysprep is run. Commands wrapped in script tags are saved to a batch file, and commands wrapped in PowerShell tags are saved to a .ps1 file (corresponds to the User Data check box on the Ec2 Service Properties dialog box).
- **Ec2ElasticGpuSetup**—Installs the Elastic GPU software package if the instance is associated with an elastic GPU.
- **Ec2FeatureLogging**—Sends Windows feature installation and corresponding service status to the console. Supported only for the Microsoft Hyper-V feature and corresponding vmms service.

Global Settings

- **ManageShutdown**—Ensures that instances launched from instance store-backed AMIs do not terminate while running Sysprep.
- **SetDnsSuffixList**—Sets the DNS suffix of the network adapter for Amazon EC2. This allows DNS resolution of servers running in Amazon EC2 without providing the fully qualified domain name.
- **WaitForMetaDataAvailable**—Ensures that the EC2Config service will wait for metadata to be accessible and the network available before continuing with the boot. This check ensures that EC2Config can obtain information from metadata for activation and other plug-ins.
- **ShouldAddRoutes**—Adds a custom route to the primary network adapter to enable the following IP addresses when multiple NICs are attached: 169.254.169.250, 169.254.169.251, and 169.254.169.254. These addresses are used by Windows Activation and when you access instance metadata.
- **RemoveCredentialsfromSysprepOnStartup**—Removes the administrator password from Sysprep.xml the next time the service starts. To ensure that this password persists, edit this setting.

DriveLetterConfig.xml

This file contains settings that control drive letter mappings. By default, a volume can be mapped to any available drive letter. You can mount a volume to a particular drive letter as follows.

```
<?xml version="1.0" standalone="yes"?>
<DriveLetterMapping>
  <Mapping>
    <VolumeName></VolumeName>
    <DriveLetter></DriveLetter>
```

```
</Mapping>
. .
<Mapping>
  <VolumeName></VolumeName>
  <DriveLetter></DriveLetter>
</Mapping>
</DriveLetterMapping>
```

- **VolumeName**—The volume label. For example, *My Volume*. To specify a mapping for an instance storage volume, use the label Temporary Storage X, where X is a number from 0 to 25.
- **DriveLetter**—The drive letter. For example, *M:*. The mapping fails if the drive letter is already in use.

EventLogConfig.xml

This file contains settings that control the event log information that's displayed on the console while the instance is booting. By default, we display the three most recent error entries from the System event log.

- **Category**—The event log key to monitor.
- **ErrorType**—The event type (for example, Error, Warning, Information.)
- **NumEntries**—The number of events stored for this category.
- **LastMessageTime**—To prevent the same message from being pushed repeatedly, the service updates this value every time it pushes a message.
- **AppName**—The event source or application that logged the event.

WallpaperSettings.xml

This file contains settings that control the information that's displayed on the desktop background. The following information is displayed by default.

- **Hostname**—Displays the computer name.
- **Instance ID**—Displays the ID of the instance.
- **Public IP Address**—Displays the public IP address of the instance.
- **Private IP Address**—Displays the private IP address of the instance.
- **Availability Zone**—Displays the Availability Zone in which the instance is running.
- **Instance Size**—Displays the type of instance.
- **Architecture**—Displays the setting of the PROCESSOR_ARCHITECTURE environment variable.

You can remove any of the information that's displayed by default by deleting its entry. You can add additional instance metadata to display as follows.

```
<WallpaperInformation>
  <name>display_name</name>
  <source>metadata</source>
  <identifier>meta-data/path</identifier>
</WallpaperInformation>
```

You can add additional System environment variables to display as follows.

```
<WallpaperInformation>
  <name>display_name</name>
  <source>EnvironmentVariable</source>
  <identifier>variable-name</identifier>
```

```
</WallpaperInformation>
```

InitializeDrivesSettings.xml

This file contains settings that control how EC2Config initializes drives.

By default, EC2Config initialize drives that were not brought online with the operating system. You can customize the plugin as follows.

```
<InitializeDrivesSettings>
  <SettingsGroup>setting</SettingsGroup>
</InitializeDrivesSettings>
```

Use a settings group to specify how you want to initialize drives:

FormatWithTRIM

Enables the TRIM command when formatting drives. After a drive has been formatted and initialized, the system restores TRIM configuration.

Starting with EC2Config version 3.18, the TRIM command is disabled during the disk format operation by default. This improves formatting times. Use this setting to enable TRIM during the disk format operation for EC2Config version 3.18 and later.

FormatWithoutTRIM

Disables the TRIM command when formatting drives and improves formatting times in Windows. After a drive has been formatted and initialized, the system restores TRIM configuration.

DisableInitializeDrives

Disables formatting for new drives. Use this setting to initialize drives manually.

Configure proxy settings for the EC2Config service

You can configure the EC2Config service to communicate through a proxy using one of the following methods: the AWS SDK for .NET, the system.net element, or Microsoft Group Policy and Internet Explorer. Using the AWS SDK for .NET is the preferred method because you can specify sign-in credentials.

Methods

- [Configure proxy settings using the AWS SDK for .NET \(Preferred\) \(p. 764\)](#)
- [Configure proxy settings using the system.net element \(p. 765\)](#)
- [Configure proxy settings using Microsoft Group Policy and Microsoft Internet Explorer \(p. 766\)](#)

Configure proxy settings using the AWS SDK for .NET (Preferred)

You can configure proxy settings for the EC2Config service by specifying the proxy element in the Ec2Config.exe.config file. For more information, see [Configuration Files Reference for AWS SDK for .NET](#).

To specify the proxy element in Ec2Config.exe.config

1. Edit the Ec2Config.exe.config file on an instance where you want the EC2Config service to communicate through a proxy. By default, the file is located in the following directory:
%ProgramFiles%\Amazon\Ec2ConfigService.

2. Add the following aws element to the configSections. Do not add this to any existing sectionGroups.

For EC2Config versions 3.17 or earlier

```
<configSections>
    <section name="aws" type="Amazon.AWSSection, AWSSDK"/>
</configSections>
```

For EC2Config versions 3.18 or later

```
<configSections>
    <section name="aws" type="Amazon.AWSSection, AWSSDK.Core"/>
</configSections>
```

3. Add the following aws element to the Ec2Config.exe.config file.

```
<aws>
    <proxy
        host="string value"
        port="string value"
        username="string value"
        password="string value" />
</aws>
```

4. Save your changes.

Configure proxy settings using the system.net element

You can specify proxy settings in a system.net element in the Ec2Config.exe.config file. For more information, see [defaultProxy Element \(Network Settings\)](#) on MSDN.

To specify the system.net element in Ec2Config.exe.config

1. Edit the Ec2Config.exe.config file on an instance where you want the EC2Config service to communicate through a proxy. By default, the file is located in the following directory:
%ProgramFiles%\Amazon\Ec2ConfigService.
2. Add a defaultProxy entry to system.net. For more information, see [defaultProxy Element \(Network Settings\)](#) on MSDN.

For example, the following configuration routes all traffic to use the proxy that is currently configured for Internet Explorer, with the exception of the metadata and licensing traffic, which will bypass the proxy.

```
<defaultProxy>
    <proxy usesystemdefault="true" />
    <bypasslist>
        <add address="169.254.169.250" />
        <add address="169.254.169.251" />
        <add address="169.254.169.254" />
        <add address="[fd00:ec2::250]" />
        <add address="[fd00:ec2::254]" />
    </bypasslist>
</defaultProxy>
```

3. Save your changes.

Configure proxy settings using Microsoft Group Policy and Microsoft Internet Explorer

The EC2Config service runs under the Local System user account. You can specify instance-wide proxy settings for this account in Internet Explorer after you change Group Policy settings on the instance.

To configure proxy settings using Group Policy and Internet Explorer

1. On an instance where you want the EC2Config service to communicate through a proxy, open a Command prompt as an Administrator, type **gpedit.msc**, and press Enter.
2. In the Local Group Policy Editor, under **Local Computer Policy**, choose **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Internet Explorer**.
3. In the right-pane, choose **Make proxy settings per-machine (rather than per-user)** and then choose **Edit policy setting**.
4. Choose **Enabled**, and then choose **Apply**.
5. Open Internet Explorer, and then choose the **Tools** button.
6. Choose **Internet Option**, and then choose the **Connections** tab.
7. Choose **LAN settings**.
8. Under **Proxy server**, choose the **Use a proxy server for your LAN** option.
9. Specify address and port information and then choose **OK**.

EC2Config version history

Windows AMIs prior to Windows Server 2016 include an optional service called the EC2Config service (`EC2Config.exe`). EC2Config starts when the instance boots and performs tasks during startup and each time you stop or start the instance. For information about the EC2Config versions included in the Windows AMIs, see [AWS Windows AMIs \(p. 41\)](#).

You can receive notifications when new versions of the EC2Config service are released. For more information, see [Subscribe to EC2Config service notifications \(p. 778\)](#).

The following table describes the released versions of EC2Config. For information about the updates for SSM Agent, see [Systems Manager SSM Agent Release Notes](#).

Version	Details	Release date
4.9.5467	<ul style="list-style-type: none">Added retry capability for discovering console port.New version of SSM Agent 3.1.2282.0.	1 August 2023
4.9.5288	<ul style="list-style-type: none">Updated AWS Core SDK to version 3.7.103.23.Fixed issue where the AWS-UpdateEC2Config SSM document fails to update EC2Config on instances enabled with only IMDSv2.New version of SSM Agent 3.1.2144.0.	8 March 2023
4.9.5231	<ul style="list-style-type: none">New version of SSM Agent 3.1.1927.0.	14 February 2023
4.9.5103	<ul style="list-style-type: none">Fixed issue where ephemeral volumes are incorrectly identified on r5d and i4i instance families.New version of SSM Agent 3.1.1856.0.	5 December 2022
4.9.5064	<ul style="list-style-type: none">Updated to use PCI segment information to select the console port.	16 November 2022

Version	Details	Release date
	<ul style="list-style-type: none"> Signed PowerShell scripts and added copyright headers. Fixed primary network adapter selection logic. New version of SSM Agent 3.1.1732.0. 	
4.9.4588	<ul style="list-style-type: none"> Updated IMDS wait logic to make only IMDSv2 requests. Added libec2launch.dll launch-agent shared library. New version of SSM Agent 3.1.1188.0. 	31 May 2022
4.9.4556	<ul style="list-style-type: none"> Added wait logic to ensure full initialization of NIC before use. New version of Log4Net 2.0.14.0 picks up security patch. New version of SSM Agent 3.1.1045.0 picks up security patch. 	1 March 2022
4.9.4536	<ul style="list-style-type: none"> Fixed issue where userdata crashes when the Temp folder is missing. New version of SSM Agent 3.1.804.0. 	31 January 2022
4.9.4508	<ul style="list-style-type: none"> Fixed issue to correctly compute diskpart script path. New version of SSM Agent 3.1.338.0. 	6 October 2021
4.9.4500	<ul style="list-style-type: none"> Updated Install-EgpuManagerConfig with IMDS v2 support. Updated web links to use https. New version of SSM Agent 3.1.282.0 	7 September 2021
4.9.4419	<ul style="list-style-type: none"> Fixed IMDS version 1 fallback logic Updated all usage of Windows temp directory to EC2Config temp directory New version of SSM Agent 3.0.1124.0 	2 June 2021
4.9.4381	<ul style="list-style-type: none"> Added support for SSM document schema version 2.2 in EC2ConfigUpdater Added AWS Nitro Enclaves package version to console log New version of SSM Agent 3.0.529.0 	4 May 2021
4.9.4326	<ul style="list-style-type: none"> Removed all links in the settings UI This is the last EC2Config version that supports Windows Server 2008. 	3 March 2021
4.9.4279	<ul style="list-style-type: none"> Fixed security issue related to Ec2ConfigMonitor scheduled task Fixed drive letter mapping issue and incorrect ephemeral disk count Added OsCurrentBuild and OsReleaseId to console output New version of SSM Agent 2.3.871.0 	11 December 2020
4.9.4222	<ul style="list-style-type: none"> Fixed IMDS version 1 fallback logic New version of SSM Agent 2.3.842.0 	7 April 2020
4.9.4122	<ul style="list-style-type: none"> Added support for IMDS v2 New version of SSM Agent 2.3.814.0 	4 March 2020

4.9.3230	<ul style="list-style-type: none"> Drive Letter Mapping description updated to better align to functionality New version of SSM Agent 2.3.372.0 	10 January 2019
4.9.3160	<ul style="list-style-type: none"> Increased wait time for primary NIC Added default configuration for RSS and Receive Queue settings for ENA devices Disabled hibernation during Sysprep New version of SSM Agent 2.3.344.0 Upgraded AWS SDK to 3.3.29.13 	15 December 2018
4.9.3067	<ul style="list-style-type: none"> Improvements made to instance hibernation New version of SSM Agent 2.3.235.0 	8 November 2018
4.9.3034	<ul style="list-style-type: none"> Added route 169.254.169.253/32 for DNS server New version of SSM Agent 2.3.193.0 	24 October 2018
4.9.2986	<ul style="list-style-type: none"> Added signing for all EC2Config related binaries New version of SSM Agent 2.3.136.0 	11 October 2018
4.9.2953	New version of SSM Agent (2.3.117.0)	2 October 2018
4.9.2926	New version of SSM Agent (2.3.68.0)	18 September 2018
4.9.2905	<ul style="list-style-type: none"> New version of SSM Agent (2.3.50.0) Added route 169.254.169.123/32 to AMZN time service Added route 169.254.169.249/32 to GRID license service Fixed an issue causing EBS NVMe volumes to be marked as ephemeral 	17 September 2018
4.9.2854	New version of SSM Agent (2.3.13.0)	17 August 2018
4.9.2831	New version of SSM Agent (2.2.916.0)	7 August 2018
4.9.2818	New version of SSM Agent (2.2.902.0)	31 July 2018

Version	Details	Release date
4.9.2756	New version of SSM Agent (2.2.800.0)	27 June 2018
4.9.2688	New version of SSM Agent (2.2.607.0)	25 May 2018
4.9.2660	New version of SSM Agent (2.2.546.0)	11 May 2018
4.9.2644	New version of SSM Agent (2.2.493.0)	26 April 2018
4.9.2586	New version of SSM Agent (2.2.392.0)	28 March 2018
4.9.2565	<ul style="list-style-type: none"> • New version of SSM Agent (2.2.355.0) • Fixed an issue on M5 and C5 instances (unable to find PV drivers) • Add console logging for instance type, newest PV drivers, and NVMe drivers 	13 March 2018
4.9.2549	New version of SSM Agent (2.2.325.0)	8 March 2018
4.9.2461	New version of SSM Agent (2.2.257.0)	15 February 2018
4.9.2439	New version of SSM Agent (2.2.191.0)	6 February 2018
4.9.2400	New version of SSM Agent (2.2.160.0)	16 January 2018
4.9.2327	<ul style="list-style-type: none"> • New version of SSM Agent (2.2.120.0) • Added COM port discovery on Amazon EC2 bare metal instances • Added Hyper-V status logging on Amazon EC2 bare metal instances 	2 January 2018
4.9.2294	New version of SSM Agent (2.2.103.0)	4 December 2017
4.9.2262	New version of SSM Agent (2.2.93.0)	15 November 2017
4.9.2246	New version of SSM Agent (2.2.82.0)	11 November 2017
4.9.2218	New version of SSM Agent (2.2.64.0)	29 October 2017
4.9.2212	New version of SSM Agent (2.2.58.0)	23 October 2017
4.9.2203	New version of SSM Agent (2.2.45.0)	19 October 2017
4.9.2188	New version of SSM Agent (2.2.30.0)	10 October 2017
4.9.2180	<ul style="list-style-type: none"> • New version of SSM Agent (2.2.24.0) • Added the Elastic GPU plugin for GPU instances 	5 October 2017
4.9.2143	New version of SSM Agent (2.2.16.0)	1 October 2017

Version	Details	Release date
4.9.2140	New version of SSM Agent (2.1.10.0)	
4.9.2130	New version of SSM Agent (2.1.4.0)	
4.9.2106	New version of SSM Agent (2.0.952.0)	
4.9.2061	New version of SSM Agent (2.0.922.0)	
4.9.2047	New version of SSM Agent (2.0.913.0)	
4.9.2031	New version of SSM Agent (2.0.902.0)	
4.9.2016	<ul style="list-style-type: none"> • New version of SSM Agent (2.0.879.0) • Fixed the CloudWatch Logs directory path for Windows Server 2003 	
4.9.1981	<ul style="list-style-type: none"> • New version of SSM Agent (2.0.847.0) • Fixed the issue with <code>important.txt</code> being generated in EBS volumes. 	
4.9.1964	New version of SSM Agent (2.0.842.0)	
4.9.1951	<ul style="list-style-type: none"> • New version of SSM Agent (2.0.834.0) • Fixed the issue with drive letter not being mapped from Z: for ephemeral drives. 	
4.9.1925	<ul style="list-style-type: none"> • New version of SSM Agent (2.0.822.0) • [Bug] This version is not a valid update target from SSM Agent v4.9.1775. 	
4.9.1900	New version of SSM Agent (2.0.805.0)	
4.9.1876	<ul style="list-style-type: none"> • New version of SSM Agent (2.0.796.0) • Fixed an issue with output/error redirection for admin userdata execution. 	
4.9.1863	<ul style="list-style-type: none"> • New version of SSM Agent (2.0.790.0) • Fixed problems with attaching multiple EBS volumes to an Amazon EC2 instance. • Improved CloudWatch to take a configuration path, keeping the backwards compatibility. 	
4.9.1791	New version of SSM Agent (2.0.767.0)	
4.9.1775	New version of SSM Agent (2.0.761.0)	
4.9.1752	New version of SSM Agent (2.0.755.0)	
4.9.1711	New version of SSM Agent (2.0.730.0)	
4.8.1676	New version of SSM Agent (2.0.716.0)	
4.7.1631	New version of SSM Agent (2.0.682.0)	
4.6.1579	<ul style="list-style-type: none"> • New version of SSM Agent (2.0.672.0) • Fixed agent update issue with v4.3, v4.4, and v4.5 	

Version	Details	Release date
4.5.1534	New version of SSM Agent (2.0.645.1)	
4.4.1503	New version of SSM Agent (2.0.633.0)	
4.3.1472	New version of SSM Agent (2.0.617.1)	
4.2.1442	New version of SSM Agent (2.0.599.0)	
4.1.1378	New version of SSM Agent (2.0.558.0)	
4.0.1343	<ul style="list-style-type: none"> • Run Command, State Manager, the CloudWatch agent, and domain join support have been moved into another agent called SSM Agent. SSM Agent will be installed as part of the EC2Config upgrade. For more information, see EC2Config and AWS Systems Manager (p. 757). • If you have a proxy set up in EC2Config, you will need to update your proxy settings for SSM Agent before upgrading. If you do not update the proxy settings, you will not be able to use Run Command to manage your instances. To avoid this, see the following information before updating to the newer version: Installing and Configuring SSM Agent on Windows Instances in the <i>AWS Systems Manager User Guide</i>. • If you previously enabled CloudWatch integration on your instances by using a local configuration file (AWS.EC2.Windows.CloudWatch.json), you will need to configure the file to work with SSM Agent. 	
3.19.1153	<ul style="list-style-type: none"> • Re-enabled activation plugin for instances with old AWS KMS configuration. Skip activation for BYOL users. • Change default TRIM behavior to be disabled during disk format operation and added FormatWithTRIM for overriding InitializeDisks plugin with userdata. 	
3.18.1118	<ul style="list-style-type: none"> • Fix to reliably add routes to the primary network adapter. • Updates to improve support for AWS services. 	
3.17.1032	<ul style="list-style-type: none"> • Fixes duplicate system logs appearing when filters set to same category. • Fixes to prevent from hanging during disk initialization. 	
3.16.930	Added support to log "Window is Ready to use" event to Windows Event Log on start.	
3.15.880	Fix to allow uploading Systems Manager Run Command output to S3 bucket names with '.' character.	
3.14.786	<p>Added support to override InitializeDisks plugin settings. For example: To speed up SSD disk initialize, you can temporarily disable TRIM by specifying this in userdata:</p> <pre><InitializeDrivesSettings><SettingsGroup>FormatWithoutTRIM</SettingsGroup></InitializeDrivesSettings></pre>	
3.13.727	Systems Manager Run Command - Fixes to process commands reliably after windows reboot.	

Version	Details	Release date
3.12.649	<ul style="list-style-type: none"> Fix to gracefully handle reboot when running commands/scripts. Fix to reliably cancel running commands. Add support for (optionally) uploading MSI logs to S3 when installing applications via Systems Manager Run Command. 	
3.11.521	<ul style="list-style-type: none"> Fixes to enable RDP thumbprint generation for Windows Server 2003. Fixes to include timezone and UTC offset in the EC2Config log lines. Systems Manager support to run Run Command commands in parallel. Roll back previous change to bring partitioned disks online. 	
3.10.442	<ul style="list-style-type: none"> Fix Systems Manager configuration failures when installing MSI applications. Fix to reliably bring storage disks online. Updates to improve support for AWS services. 	
3.9.359	<ul style="list-style-type: none"> Fix in post Sysprep script to leave the configuration of windows update in a default state. Fix the password generation plugin to improve the reliability in getting GPO password policy settings. Restrict EC2Config/SSM log folder permissions to the local Administrators group. Updates to improve support for AWS services. 	
3.8.294	<ul style="list-style-type: none"> Fixed an issue with CloudWatch that prevented logs from getting uploaded when not on primary drive. Improved the disk initialization process by adding retry logic. Added improved error handling when the SetPassword plugin occasionally failed during AMI creation. Updates to improve support for AWS services. 	
3.7.308	<ul style="list-style-type: none"> Improvements to the ec2config-cli utility for config testing and troubleshooting within instance. Avoid adding static routes for AWS KMS and meta-data service on an OpenVPN adapter. Fixed an issue where user-data execution was not honoring the "persist" tag. Improved error handling when logging to the EC2 console is not available. Updates to improve support for AWS services. 	
3.6.269	<ul style="list-style-type: none"> Windows activation reliability fix to first use link local address 169.254.0.250/251 for activating windows via AWS KMS Improved proxy handling for Systems Manager, Windows Activation and Domain Join scenarios Fixed an issue where duplicate lines of user accounts were added to the Sysprep answer file 	

Version	Details	Release date
3.5.228	<ul style="list-style-type: none"> Addressed a scenario where the CloudWatch plugin may consume excessive CPU and memory reading Windows Event Logs Added a link to the CloudWatch configuration documentation in the EC2Config Settings UI 	
3.4.212	<ul style="list-style-type: none"> Fixes to EC2Config when used in combination with VM-Import. Fixed service naming issue in the WiX installer. 	
3.3.174	<ul style="list-style-type: none"> Improved exception handling for Systems Manager and domain join failures. Change to support Systems Manager SSM schema versioning. Fixed formatting ephemeral disks on Win2K3. Change to support configuring disk size greater than 2TB. Reduced virtual memory usage by setting GC mode to default. Support for downloading artifacts from UNC path in aws:psModule and aws:application plugin. Improved logging for Windows activation plugin. 	
3.2.97	<ul style="list-style-type: none"> Performance improvements by delay loading Systems Manager SSM assemblies. Improved exception handling for malformed sysprep2008.xml. Command line support for Systems Manager "Apply" configuration. Change to support domain join when there is a pending computer rename. Support for optional parameters in the aws:applications plugin. Support for command array in aws:psModule plugin. 	
3.0.54	<ul style="list-style-type: none"> Enable support for Systems Manager. Automatically domain join EC2 Windows instances to an AWS directory via Systems Manager. Configure and upload CloudWatch logs/metrics via Systems Manager. Install PowerShell modules via Systems Manager. Install MSI applications via Systems Manager. 	
2.4.233	<ul style="list-style-type: none"> Added scheduled task to recover EC2Config from service startup failures. Improvements to the Console log error messages. Updates to improve support for AWS services. 	
2.3.313	<ul style="list-style-type: none"> Fixed an issue with large memory consumption in some cases when the CloudWatch Logs feature is enabled. Fixed an upgrade bug so that ec2config versions lower than 2.1.19 can now upgrade to latest. Updated COM port opening exception to be more friendly and useful in logs. Ec2configServiceSettings UI disabled resizing and fixed the attribution and version display placement in UI. 	

Version	Details	Release date
2.2.12	<ul style="list-style-type: none"> Handled NullPointerException while querying a registry key for determining Windows Sysprep state which returned null occasionally. Freed up unmanaged resources in finally block. 	
2.2.11	Fixed a issue in CloudWatch plugin for handling empty log lines.	
2.2.10	<ul style="list-style-type: none"> Removed configuring CloudWatch Logs settings through UI. Enable users to define CloudWatch Logs settings in %ProgramFiles%\Amazon\Ec2ConfigService\Settings \AWS.EC2.Windows.CloudWatch.json file to allow future enhancements. 	
2.2.9	Fixed unhandled exception and added logging.	
2.2.8	<ul style="list-style-type: none"> Fixes Windows OS version check in EC2Config Installer to support Windows Server 2003 SP1 and later. Fixes null value handling when reading registry keys related to updating Sysprep config files. 	
2.2.7	<ul style="list-style-type: none"> Added support for EC2Config to run during Sysprep execution for Windows 2008 and greater. Improved exception handling and logging for better diagnostics 	
2.2.6	<ul style="list-style-type: none"> Reduced the load on the instance and on CloudWatch Logs when uploading log events. Addressed an upgrade issue where the CloudWatch Logs plug-in did not always stay enabled 	
2.2.5	<ul style="list-style-type: none"> Added support to upload logs to CloudWatch Log Service. Fixed a race condition issue in Ec2OutputRDPCert plug-in Changed EC2Config Service recovery option to Restart from TakeNoAction Added more exception information when EC2Config Crashes 	
2.2.4	<ul style="list-style-type: none"> Fixed a typo in PostSysprep.cmd Fixed the bug which EC2Config does not pin itself onto start menu for OS2012+ 	
2.2.3	<ul style="list-style-type: none"> Added option to install EC2Config without service starting immediately upon install. To use, run 'Ec2Install.exe start=false' from the command prompt Added parameter in wallpaper plugin to control adding/ removing wallpaper. To use, run 'Ec2WallpaperInfo.exe set' or 'Ec2WallpaperInfo.exe revert' from the command prompt Added checking for RealTimelsUniversal key, output incorrect settings of the RealTimelsUniversal registry key to the Console Removed EC2Config dependency on Windows temp folder Removed UserData execution dependency on .Net 3.5 	
2.2.2	<ul style="list-style-type: none"> Added check to service stop behavior to check that resources are being released Fixed issue with long execution times when joined to domain 	

Version	Details	Release date
2.2.1	<ul style="list-style-type: none"> Updated Installer to allow upgrades from older versions Fixed Ec2WallpaperInfo bug in .Net4.5 only environment Fixed intermittent driver detection bug Added silent install option. Execute Ec2Install.exe with the '-q' option. eg: 'Ec2Install.exe -q' 	
2.2.0	<ul style="list-style-type: none"> Added support for .Net4 and .Net4.5 only environments Updated Installer 	
2.1.19	<ul style="list-style-type: none"> Added ephemeral disk labeling support when using Intel network driver (eg. C3 instance Type). For more information, see Enhanced networking on Windows (p. 1326). Added AMI Origin Version and AMI Origin Name support to the console output Made changes to the Console Output for consistent formatting/parsing Updated Help File 	
2.1.18	<ul style="list-style-type: none"> Added EC2Config WMI Object for Completion notification (- Namespace root\Amazon -Class EC2_ConfigService) Improved Performance of Startup WMI query with large Event Logs; could cause prolonged high CPU during initial execution 	
2.1.17	<ul style="list-style-type: none"> Fixed UserData execution issue with Standard Output and Standard Error buffer filling Fixed incorrect RDP thumbprint sometimes appearing in Console Output for >= w2k8 OS Console Output now contains 'RDPCERTIFICATE-SubjectName:' for Windows 2008+, which contains the machine name value Added D:\ to Drive Letter Mapping dropdown Moved Help button to top right and changed look/feel Added Feedback survey link to top right 	
2.1.16	<ul style="list-style-type: none"> General Tab includes link to EC2Config download page for new Versions Desktop Wallpaper overlay now stored in Users Local Appdata folder instead of My Documents to support MyDoc redirection MSSQLServer name sync'd with system in Post-Sysprep script (2008+) Reordered Application Folder (moved files to Plugin directory and removed duplicate files) Changed System Log Output (Console): <ul style="list-style-type: none"> *Moved to a date, name, value format for easier parsing (Please start migrating dependencies to new format) *Added 'Ec2SetPassword' plugin status *Added Sysprep Start and End times Fixed issue of Ephemeral Disks not being labeled as 'Temporary Storage' for non-english Operating Systems Fixed EC2Config Uninstall failure after running Sysprep 	

Version	Details	Release date
2.1.15	<ul style="list-style-type: none"> Optimized requests to the Metadata service Metadata now bypass Proxy Settings Ephemeral Disks labeled as 'Temporary Storage' and Important.txt placed on volume when found (Citrix PV drivers only). For more information, see Upgrade PV drivers on Windows instances (p. 786). Ephemeral Disks assigned drive letters from Z to A (Citrix PV drivers only) - assignment can be overwritten using Drive Letter Mapping plugin with Volume labels 'Temporary Storage X' where x is a number 0-25) UserData now runs immediately following 'Windows is Ready' 	
2.1.14	Desktop wallpaper fixes	
2.1.13	<ul style="list-style-type: none"> Desktop wallpaper will display hostname by default Removed dependency on Windows Time service Route added in cases where multiple IPs are assigned to a single interface 	
2.1.11	<ul style="list-style-type: none"> Changes made to Ec2Activation Plugin -Verifies Activation status every 30 days -If Grace Period has 90 days remaining (out of 180), reattempts activation 	
2.1.10	<ul style="list-style-type: none"> Desktop wallpaper overlay no longer persists with Sysprep or Shutdown without Sysprep Userdata option to run on every service start with <persist>true</persist> Changed location and name of /DisableWinUpdate.cmd to / Scripts/PostSysprep.cmd Administrator password set to not expire by default in /Scripts/ PostSysprep.cmd Uninstall will remove EC2Config PostSysprep script from c:\windows\setup\script\CommandComplete.cmd Add Route supports custom interface metrics 	
2.1.9	UserData Execution no longer limited to 3851 Characters	
2.1.7	<ul style="list-style-type: none"> OS Version and language identifier written to console EC2Config version written to console PV driver version written to console Detection of Bug Check and output to the console on next boot when found Option added to config.xml to persist Sysprep credentials Add Route Retry logic in cases of ENI being unavailable at start User Data execution PID written to console Minimum generated password length retrieved from GPO Set service start to retry 3 attempts Added S3_DownloadFile.ps1 and S3_Upload file.ps1 examples to /Scripts folder 	

Version	Details	Release date
2.1.6	<ul style="list-style-type: none"> • Version information added to General tab • Renamed the Bundle tab to Image • Simplified the process of specifying passwords and moved the password-related UI from the General tab to the Image tab • Renamed the Disk Settings tab to Storage • Added a Support tab with common tools for troubleshooting • Windows Server 2003 sysprep.ini set to extend OS partition by default • Added the private IP address to the wallpaper • Private IP address displayed on wallpaper • Added retry logic for Console output • Fixed Com port exception for metadata accessibility -- caused EC2Config to terminate before console output is displayed • Checks for activation status on every boot -- activates as necessary • Fixed issue of relative paths -- caused when manually executing wallpaper shortcut from startup folder; pointing to Administrator/logs • Fixed default background color for Windows Server 2003 user (other than Administrator) 	
2.1.2	<ul style="list-style-type: none"> • Console timestamps in UTC (Zulu) • Removed appearance of hyperlink on Sysprep tab • Addition of feature to dynamically expand Root Volume on first boot for Windows 2008+ • When Set-Password is enabled, now automatically enables EC2Config to set the password • EC2Config checks activation status prior to running Sysprep (presents warning if not activated) • Windows Server 2003 Sysprep.xml now defaults to UTC timezone instead of Pacific • Randomized Activation Servers • Renamed Drive Mapping tab to Disk Settings • Moved Initialize Drives UI items from General to the Disk Settings tab • Help button now points to HTML help file • Updated HTML help file with changes • Updated 'Note' text for Drive Letter Mappings • Added InstallUpdates.ps1 to /Scripts folder for automating Patches and cleanup prior to Sysprep 	
2.1.0	<ul style="list-style-type: none"> • Desktop wallpaper displays instance information by default upon first logon (not disconnect/reconnect) • PowerShell can be run from the userdata by surrounding the code with <powershell></powershell> 	

Subscribe to EC2Config service notifications

Amazon SNS can notify you when new versions of the EC2Config service are released. Use the following procedure to subscribe to these notifications.

To subscribe to EC2Config notifications

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must select this Region because the SNS notifications that you are subscribing to were created in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. In the **Create subscription** dialog box, do the following:
 - a. For **Topic ARN**, use the following Amazon Resource Name (ARN):

arn:aws:sns:us-east-1:801119661308:ec2-windows-ec2config
 - b. For **Protocol**, choose Email.
 - c. For **Endpoint**, type an email address that you can use to receive the notifications.
 - d. Choose **Create subscription**.
6. You'll receive an email asking you to confirm your subscription. Open the email and follow the directions to complete your subscription.

Whenever a new version of the EC2Config service is released, we send notifications to subscribers. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

To unsubscribe from EC2Config notifications

1. Open the Amazon SNS console.
2. In the navigation pane, choose **Subscriptions**.
3. Select the subscription and then choose **Actions, Delete subscriptions**. When prompted for confirmation, choose **Delete**.

Troubleshoot issues with the EC2Config service

The following information can help you troubleshoot issues with the EC2Config service.

Update EC2Config on an unreachable instance

Use the following procedure to update the EC2Config service on a Windows Server instance that is inaccessible using Remote Desktop.

To update EC2Config on an Amazon EBS-backed Windows instance that you can't connect to

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Locate the affected instance. Select the instance and choose **Instance state**, and then choose **Stop instance**.

Warning

When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

4. Choose **Launch instances** and create a temporary t2.micro instance in the same Availability Zone as the affected instance. Use a different AMI than the one that you used to launch the affected instance.

Important

If you do not create the instance in the same Availability Zone as the affected instance you will not be able to attach the root volume of the affected instance to the new instance.

5. In the EC2 console, choose **Volumes**.
6. Locate the root volume of the affected instance. [Detach the volume \(p. 1752\)](#) and then [attach the volume \(p. 1729\)](#) to the temporary instance that you created earlier. Attach it with the default device name (xvdf).
7. Use Remote Desktop to connect to the temporary instance, and then use the Disk Management utility to [make the volume available for use \(p. 1731\)](#).
8. [Download](#) the latest version of the EC2Config service. Extract the files from the .zip file to the Temp directory on the drive you attached.
9. On the temporary instance, open the Run dialog box, type **regedit**, and press Enter.
10. Choose HKEY_LOCAL_MACHINE. From the **File** menu, choose **Load Hive**. Choose the drive and then navigate to and open the following file: Windows\System32\config\SOFTWARE. When prompted, specify a key name.
11. Select the key you just loaded and navigate to Microsoft\Windows\CurrentVersion. Choose the RunOnce key. If this key doesn't exist, choose CurrentVersion from the context (right-click) menu, choose **New** and then choose **Key**. Name the key RunOnce.
12. From the context (right-click) menu choose the RunOnce key, choose **New** and then choose **String Value**. Enter Ec2Install as the name and C:\Temp\Ec2Install.exe /quiet as the data.
13. Choose the HKEY_LOCAL_MACHINE*specified key name*\Microsoft\Windows NT \CurrentVersion\Winlogon key. From the context (right-click) menu choose **New**, and then choose **String Value**. Enter AutoAdminLogon as the name and 1 as the value data.
14. Choose the HKEY_LOCAL_MACHINE*specified key name*\Microsoft\Windows NT \CurrentVersion\Winlogon> key. From the context (right-click) menu choose **New**, and then choose **String Value**. Enter DefaultUserName as the name and Administrator as the value data.
15. Choose the HKEY_LOCAL_MACHINE*specified key name*\Microsoft\Windows NT \CurrentVersion\Winlogon key. From the context (right-click) menu choose **New**, and then choose **String Value**. Type DefaultPassword as the name and enter a password in the value data.
16. In the Registry Editor navigation pane, choose the temporary key that you created when you first opened Registry Editor.
17. From the **File** menu, choose **Unload Hive**.
18. In Disk Management Utility, choose the drive you attached earlier, open the context (right-click) menu, and choose **Offline**.
19. In the Amazon EC2 console, detach the affected volume from the temporary instance and reattach it to your instance with the device name /dev/sda1. You must specify this device name to designate the volume as a root volume.
20. [Stop and start your instance \(p. 594\)](#) the instance.
21. After the instance starts, check the system log and verify that you see the message Windows is ready to use.
22. Open Registry Editor and choose HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT \CurrentVersion\Winlogon. Delete the String Value keys you created earlier: **AutoAdminLogon**, **DefaultUserName**, and **DefaultPassword**.
23. Delete or stop the temporary instance you created in this procedure.

Paravirtual drivers for Windows instances

Windows AMIs contain a set of drivers to permit access to virtualized hardware. These drivers are used by Amazon EC2 to map instance store and Amazon EBS volumes to their devices. The following table shows key differences between the different drivers.

	RedHat PV	Citrix PV	AWS PV
Instance type	Not supported for all instance types. If you specify an unsupported instance type, the instance is impaired.	Supported for Xen instance types.	Supported for Xen instance types.
Attached volumes	Supports up to 16 attached volumes.	Supports more than 16 attached volumes.	Supports more than 16 attached volumes.
Network	The driver has known issues where the network connection resets under high loads; for example, fast FTP file transfers.		The driver automatically configures jumbo frames on the network adapter when on a compatible instance type. When the instance is in a cluster placement group (p. 1352) , this offers better network performance between instances in the cluster placement group.

The following table shows which PV drivers you should run on each version of Windows Server on Amazon EC2.

Windows Server version	PV driver version
Windows Server 2022	AWS PV latest version
Windows Server 2019	AWS PV latest version
Windows Server 2016	AWS PV latest version
Windows Server 2012 R2	AWS PV latest version

Windows Server version	PV driver version
Windows Server 2012	AWS PV latest version
Windows Server 2008 R2	AWS PV version 8.3.5
Windows Server 2008	Citrix PV 5.9
Windows Server 2003	Citrix PV 5.9

- [Troubleshoot PV drivers \(p. 791\)](#)

AWS PV drivers

The AWS PV drivers are stored in the %ProgramFiles%\Amazon\Xentools directory. This directory also contains public symbols and a command line tool, xenstore_client.exe, that enables you to access entries in XenStore. For example, the following PowerShell command returns the current time from the Hypervisor:

```
PS C:\> [DateTime]::FromFileTimeUTC((gwmi -n root\wmi -cl
AWSXenStoreBase).XenTime).ToString("hh:mm:ss")
11:17:00
```

The AWS PV driver components are listed in the Windows registry under HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services. These driver components are as follows: xenbus, xeniface, xennet, xenvbd, and xenvif.

AWS PV drivers also have a Windows service named LiteAgent, which runs in user-mode. It handles tasks such as shutdown and restart events from AWS APIs on Xen generation instances. You can access and manage services by running Services.msc from the command line. When running on Nitro generation instances, the AWS PV drivers are not used and the LiteAgent service will self-stop starting with driver version 8.2.4. Updating to the latest AWS PV driver also updates the LiteAgent and improves reliability on all instance generations.

Install the latest AWS PV drivers

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](#).

Amazon Windows AMIs contain a set of drivers to permit access to virtualized hardware. These drivers are used by Amazon EC2 to map instance store and Amazon EBS volumes to their devices. We recommend that you install the latest drivers to improve stability and performance of your EC2 Windows instances.

Installation options

- You can use AWS Systems Manager to automatically update the PV drivers. For more information, see [Walkthrough: Automatically Update PV Drivers on EC2 Windows Instances \(Console\)](#) in the [AWS Systems Manager User Guide](#).
- You can [download](#) the driver package and run the install program manually. Be sure to check the `readme.txt` file for system requirements. For information about downloading and installing the AWS PV drivers, or upgrading a domain controller, see [Upgrade Windows Server instances \(AWS PV upgrade\) \(p. 786\)](#).

AWS PV driver package history

The following table shows the changes to AWS PV drivers for each driver release.

Package version	Details	Release date
8.4.3	Fixed bugs in the package installer to improve the upgrade experience.	24 January 2023
8.4.2	Stability fixes to address race condition.	13 April 2022
8.4.1	Improved package installer.	7 January 2022
8.4.0	<ul style="list-style-type: none">• Stability fixes to address rare cases of stuck disk IO.• Stability fixes to address rare cases of crashes during EBS volume detachment.• Added feature to distribute load across multiple cores for workloads that leverage more than 20,000 IOPS and experience degradation due to bottlenecks. To enable this feature, see Workloads that leverage more than 20,000 disk IOPS experience degradation due to CPU bottlenecks (p. 796).• AWS PV 8.4 installation on Windows Server 2008 R2 will fail. AWS PV version 8.3.5 and earlier are supported on Windows Server 2008 R2.	2 March 2021
8.3.5	Improved package installer.	7 January 2022
8.3.4	Improved reliability of network device attachment.	4 August 2020
8.3.3	<ul style="list-style-type: none">• Update to XenStore-facing component to prevent bug check during error-handling paths.• Update to storage component to avoid crashes when an invalid SRB is submitted. <p>To update this driver on Windows Server 2008 R2 instances, you must first verify that the appropriate patches are installed to address the following Microsoft Security Advisory: Microsoft Security Advisory 3033929.</p>	4 February 2020
8.3.2	Enhanced reliability of networking components.	30 July 2019
8.3.1	Improved performance and robustness of storage component.	12 June 2019

Package version	Details	Release date
<u>8.2.7</u>	Improved efficiency to support migrating to latest generation instance types.	20 May 2019
<u>8.2.6</u>	Improved efficiency of crash dump path.	15 January 2019
<u>8.2.5</u>	Additional security enhancements. PowerShell installer now available in package.	12 December 2018
<u>8.2.4</u>	Reliability improvements.	2 October 2018
<u>8.2.3</u>	Bug fixes and performance improvements. Report EBS volume ID as disk serial number for EBS volumes. This enables cluster scenarios such as S2D.	29 May 2018
<u>8.2.1</u>	Network and storage performance improvements plus multiple robustness fixes. To verify that this version has been installed, refer to the following Windows registry value: HKLM\Software\Amazon\PVDriver\Version 8.2.1.	8 March 2018
<u>7.4.6</u>	Stability fixes to make AWS PV drivers more resilient.	26 April 2017
7.4.3	Added support for Windows Server 2016. Stability fixes for all supported Windows OS versions. *AWS PV driver version 7.4.3's signature expires on March 29, 2019. We recommend updating to the latest AWS PV driver.	18 Nov 2016
7.4.2	Stability fixes for support of X1 instance type.	2 Aug 2016
7.4.1	<ul style="list-style-type: none"> • Performance improvement in AWS PV Storage driver. • Stability fixes in AWS PV Storage driver: Fixed an issue where the instances were hitting a system crash with bug check code 0x0000DEAD. • Stability fixes in AWS PV Network driver. • Added support for Windows Server 2008R2. 	12 July 2016
7.3.2	<ul style="list-style-type: none"> • Improved logging and diagnostics. • Stability fix in AWS PV Storage driver. In some cases disks may not surface in Windows after reattaching the disk to the instance. • Added support for Windows Server 2012. 	24 June 2015
7.3.1	TRIM update: Fix related to TRIM requests. This fix stabilizes instances and improves instance performance when managing large numbers of TRIM requests.	
7.3.0	TRIM support: The AWS PV driver now sends TRIM requests to the hypervisor. Ephemeral disks will properly process TRIM requests given the underlying storage supports TRIM (SSD). Note that EBS-based storage does not support TRIM as of March 2015.	

Package version	Details	Release date
7.2.5	<ul style="list-style-type: none"> • Stability fix in AWS PV Storage drivers: In some cases the AWS PV driver could dereference invalid memory and cause a system failure. • Stability fix while generating a crash dump: In some cases the AWS PV driver could get stuck in a race condition when writing a crash dump. Before this release, the issue could only be resolved by forcing the driver to stop and restart which lost the memory dump. 	
7.2.4	Device ID persistence: This driver fix masks the platform PCI device ID and forces the system to always surface the same device ID, even if the instance is moved. More generally, the fix affects how the hypervisor surfaces virtual devices. The fix also includes modifications to the co-installer for the AWS PV drivers so the system persists mapped virtual devices.	
7.2.2	<ul style="list-style-type: none"> • Load the AWS PV drivers in Directory Services Restore Mode (DSRM) mode: Directory Services Restore Mode is a safe mode boot option for Windows Server domain controllers. • Persist device ID when virtual network adapter device is reattached: This fix forces the system to check the MAC address mapping and persist the device ID. This fix ensures that adapters retain their static settings if the adapters are reattached. 	
7.2.1	<ul style="list-style-type: none"> • Run in safe mode: Fixed an issue where the driver would not load in safe mode. Previously the AWS PV Drivers would only instantiate in normal running systems. • Add disks to Microsoft Windows Storage Pools: Previously we synthesized page 83 queries. The fix disabled page 83 support. Note this does not affect storage pools that are used in a cluster environment because PV disks are not valid cluster disks. 	
7.2.0	Base: The AWS PV base version.	

Citrix PV drivers

The Citrix PV drivers are stored in the %ProgramFiles%\Citrix\XenTools (32-bit instances) or %ProgramFiles(x86)%\Citrix\XenTools (64-bit instances) directory.

The Citrix PV driver components are listed in the Windows registry under HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services. These driver components are as follows: xenevtchn, xeniface, xennet, Xennet6, xensvc, xenvbd, and xenvif.

Citrix also has a driver component named XenGuestAgent, which runs as a Windows service. It handles tasks such as shutdown and restart events from the API. You can access and manage services by running Services.msc from the command line.

If you are encountering networking errors while performing certain workloads, you may need to disable the TCP offloading feature for the Citrix PV driver. For more information, see [TCP offloading \(p. 795\)](#).

RedHat PV drivers

RedHat drivers are supported for legacy instances, but are not recommended on newer instances with more than 12GB of RAM due to driver limitations. Instances with more than 12GB of RAM running

RedHat drivers can fail to boot and become inaccessible. We recommend upgrading RedHat drivers to Citrix PV drivers, and then upgrade Citrix PV drivers to AWS PV drivers.

The source files for the RedHat drivers are in the %ProgramFiles%\RedHat (32-bit instances) or %ProgramFiles(x86)%\RedHat (64-bit instances) directory. The two drivers are rhelnet, the RedHat Paravirtualized network driver, and rhelscsi, the RedHat SCSI miniport driver.

Subscribe to notifications

Amazon SNS can notify you when new versions of EC2 Windows Drivers are released. Use one of the following methods to subscribe to these notifications.

Note

You must specify the Region for the SNS Topic you subscribe to.

Subscribe to EC2 notifications from the console

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must select this Region because the SNS notifications that you are subscribing to are in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. In the **Create subscription** dialog box, do the following:
 - a. For **TopicARN**, copy the following Amazon Resource Name (ARN):
`arn:aws:sns:us-east-1:801119661308:ec2-windows-drivers`
 - b. For **Protocol**, choose Email.
 - c. For **Endpoint**, type an email address that you can use to receive the notifications.
 - d. Choose **Create subscription**.
6. You'll receive a confirmation email. Open the email and follow the directions to complete your subscription.

Subscribe to EC2 notifications using the AWS CLI

To subscribe to EC2 notifications with the AWS CLI, use the following command.

```
aws sns subscribe --topic-arn arn:aws:sns:us-east-1:801119661308:ec2-windows-drivers --region us-east-1 --protocol email --notification-endpoint YourUserName@YourDomainName.ext
```

Subscribe to EC2 notifications using the AWS Tools for PowerShell

To subscribe to EC2 notifications with Tools for Windows PowerShell, use the following command.

```
Connect-SNSNotification -TopicArn 'arn:aws:sns:us-east-1:801119661308:ec2-windows-drivers' -Region us-east-1 -Protocol email -Endpoint 'YourUserName@YourDomainName.ext'
```

Whenever new EC2 Windows drivers are released, we send notifications to subscribers. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

Unsubscribe from Amazon EC2 Windows driver notification

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation pane, choose **Subscriptions**.

3. Select the check box for the subscription and then choose **Actions, Delete subscriptions**. When prompted for confirmation, choose **Delete**.

Upgrade PV drivers on Windows instances

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](#).

We recommend that you install the latest PV drivers to improve the stability and performance of your EC2 Windows instances. The directions on this page help you download the driver package and run the install program.

To verify which driver your Windows instance uses

Open **Network Connections** in Control Panel and view **Local Area Connection**. Check whether the driver is one of the following:

- AWS PV Network Device
- Citrix PV Ethernet Adapter
- RedHat PV NIC Driver

Alternatively, you can check the output from the `pnputil -e` command.

System requirements

Be sure to check the `readme.txt` file in the download for system requirements.

Contents

- [Upgrade Windows Server instances \(AWS PV upgrade\) \(p. 786\)](#)
- [Upgrade a domain controller \(AWS PV upgrade\) \(p. 787\)](#)
- [Upgrade Windows Server 2008 and 2008 R2 instances \(Redhat to Citrix PV upgrade\) \(p. 789\)](#)
- [Upgrade your Citrix Xen guest agent service \(p. 791\)](#)

Upgrade Windows Server instances (AWS PV upgrade)

Use the following procedure to perform an in-place upgrade of AWS PV drivers, or to upgrade from Citrix PV drivers to AWS PV drivers on Windows Server 2008 R2, Windows Server 2012, Windows Server 2012 R2, Windows Server 2016, Windows Server 2019, or Windows Server 2022. This upgrade is not available for RedHat drivers, or for other versions of Windows Server.

Some older versions of Windows Server can't use the latest drivers. To verify which driver version to use for your operating system, see the driver version table in the [Paravirtual drivers for Windows instances \(p. 780\)](#) page.

Important

If your instance is a domain controller, see [Upgrade a domain controller \(AWS PV upgrade\) \(p. 787\)](#). The upgrade process for domain controller instances is different than standard editions of Windows.

To upgrade AWS PV drivers

1. We recommend that you create an AMI as a backup as follows, in case you need to roll back your changes.

- a. When you stop an instance, the data on any instance store volumes is erased. Before you stop an instance, verify that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
 - b. In the navigation pane, choose **Instances**.
 - c. Select the instance that requires the driver upgrade, and choose **Instance state, Stop instance**.
 - d. After the instance is stopped, select the instance, choose **Actions**, then **Image and templates**, and then choose **Create image**.
 - e. Choose **Instance state, Start instance**.
2. Connect to the instance using Remote Desktop.
 3. We recommend that you take all non-system disks offline and note any drive letter mappings to the secondary disks in Disk Management before you perform this upgrade. This step is not required if you are performing an in-place update of AWS PV drivers. We also recommend setting non-essential services to **Manual** start-up in the Services console.
 4. [Download](#) the latest driver package to the instance.

Or, run the following PowerShell command:

```
Invoke-WebRequest https://s3.amazonaws.com/ec2-windows-drivers-downloads/AWSPV/Latest/AWSPVDriver.zip -outfile $env:USERPROFILE\pv_driver.zip  
Expand-Archive $env:UserProfile\pv_driver.zip -DestinationPath  
$env:UserProfile\pv_drivers
```

5. Extract the contents of the folder and then run AWSPVDriverSetup.msi.

After running the MSI, the instance automatically reboots and then upgrades the driver. The instance will not be available for up to 15 minutes. After the upgrade is complete and the instance passes both health checks in the Amazon EC2 console, you can verify that the new driver was installed by connecting to the instance using Remote Desktop and then running the following PowerShell command:

```
Get-ItemProperty HKLM:\SOFTWARE\Amazon\PVDriver
```

Verify that the driver version is the same as the latest version listed in the Driver Version History table. For more information, see [AWS PV driver package history \(p. 782\)](#) Open Disk Management to review any offline secondary volumes and bring them online corresponding to the drive letters noted in Step 6.

If you previously disabled [TCP offloading \(p. 795\)](#) using Netsh for Citrix PV drivers we recommend that you re-enable this feature after upgrading to AWS PV drivers. TCP Offloading issues with Citrix drivers are not present in the AWS PV drivers. As a result, TCP Offloading provides better performance with AWS PV drivers.

If you previously applied a static IP address or DNS configuration to the network interface, you might need to reapply the static IP address or DNS configuration after upgrading AWS PV drivers.

Upgrade a domain controller (AWS PV upgrade)

Use the following procedure on a domain controller to perform either an in-place upgrade of AWS PV drivers, or to upgrade from Citrix PV drivers to AWS PV drivers.

To upgrade a domain controller

1. We recommend that you create a backup of your domain controller in case you need to roll back your changes. Using an AMI as a backup is not supported. For more information, see [Backup and Restore Considerations for Virtualized Domain Controllers](#) in the Microsoft documentation.
2. Run the following command to configure Windows to boot into Directory Services Restore Mode (DSRM).

Warning

Before running this command, confirm that you know the DSRM password. You'll need this information so that you can log in to your instance after the upgrade is complete and the instance automatically reboots.

```
bcdedit /set {default} safeboot dsrepair
```

PowerShell:

```
PS C:\> bcdedit /set "{default}" safeboot dsrepair
```

The system must boot into DSRM because the upgrade utility removes Citrix PV storage drivers so it can install AWS PV drivers. Therefore we recommend noting any drive letter and folder mappings to the secondary disks in Disk Management. When Citrix PV storage drivers are not present, secondary drives are not detected. Domain controllers that use an NTDS folder on secondary drives will not boot because the secondary disk is not detected.

Warning

After you run this command do not manually reboot the system. The system will be unreachable because Citrix PV drivers do not support DSRM.

3. Run the following command to add **DisableDCCheck** to the registry:

```
reg add HKLM\SOFTWARE\Wow6432Node\Amazon\AWSPVDriverSetup /v DisableDCCheck /t REG_SZ /d true
```

4. [Download](#) the latest driver package to the instance.
5. Extract the contents of the folder and then run AWSPVDriverSetup.msi.

After running the MSI, the instance automatically reboots and then upgrades the driver. The instance will not be available for up to 15 minutes.

6. After the upgrade is complete and the instance passes both health checks in the Amazon EC2 console, connect to the instance using Remote Desktop. Open Disk Management to review any offline secondary volumes and bring them online corresponding to the drive letters and folder mappings noted earlier.

You must connect to the instance by specifying the user name in the following format *hostname\administrator*. For example, Win2k12TestBox\administrator.

7. Run the following command to remove the DSRM boot configuration:

```
bcdedit /deletevalue safeboot
```

8. Reboot the instance.
9. To complete the upgrade process, verify that the new driver was installed. In Device Manager, under **Storage Controllers**, locate **AWS PV Storage Host Adapter**. Verify that the driver version is the same as the latest version listed in the Driver Version History table. For more information, see [AWS PV driver package history \(p. 782\)](#).

10. Run the following command to delete **DisableDCCheck** from the registry:

```
reg delete HKLM\SOFTWARE\Wow6432Node\Amazon\AWSPVDriverSetup /v DisableDCCheck
```

Note

If you previously disabled [TCP offloading \(p. 795\)](#) using Netsh for Citrix PV drivers we recommend that you re-enable this feature after upgrading to AWS PV Drivers. TCP Offloading

issues with Citrix drivers are not present in the AWS PV drivers. As a result, TCP Offloading provides better performance with AWS PV drivers.

Upgrade Windows Server 2008 and 2008 R2 instances (Redhat to Citrix PV upgrade)

Before you start upgrading your RedHat drivers to Citrix PV drivers, make sure you do the following:

- Install the latest version of the EC2Config service. For more information, see [Install the latest version of EC2Config \(p. 755\)](#).
- Verify that you have Windows PowerShell 3.0 installed. To verify the version that you have installed, run the following command in a PowerShell window:

```
PS C:\> $PSVersionTable.PSVersion
```

Windows PowerShell 3.0 is bundled in the Windows Management Framework (WMF) version 3.0 install package. If you need to install Windows PowerShell 3.0, see [Windows Management Framework 3.0](#) in the Microsoft Download Center.

- Back up your important information on the instance, or create an AMI from the instance. For more information about creating an AMI, see [Create a custom Windows AMI \(p. 151\)](#). If you create an AMI, make sure that you do the following:
 - Write down your password.
 - Do not run the Sysprep tool manually or using the EC2Config service.
 - Set your Ethernet adapter to obtain an IP address automatically using DHCP. For more information, see [Configure TCP/IP Settings](#) in the Microsoft TechNet Library.

To upgrade RedHat drivers

1. Connect to your instance and log in as the local administrator. For more information about connecting to your instance, see [Connect to your Windows instance \(p. 626\)](#).
2. In your instance, [download](#) the Citrix PV upgrade package.
3. Extract the contents of the upgrade package to a location of your choice.
4. Double-click the **Upgrade.bat** file. If you get a security warning, choose **Run**.
5. In the **Upgrade Drivers** dialog box, review the information and choose **Yes** if you are ready to start the upgrade.
6. In the **Red Hat Paravirtualized Xen Drivers for Windows uninstaller** dialog box, choose **Yes** to remove the RedHat software. Your instance will be rebooted.

Note

If you do not see the uninstaller dialog box, choose **Red Hat Paravirtualize** in the Windows taskbar.

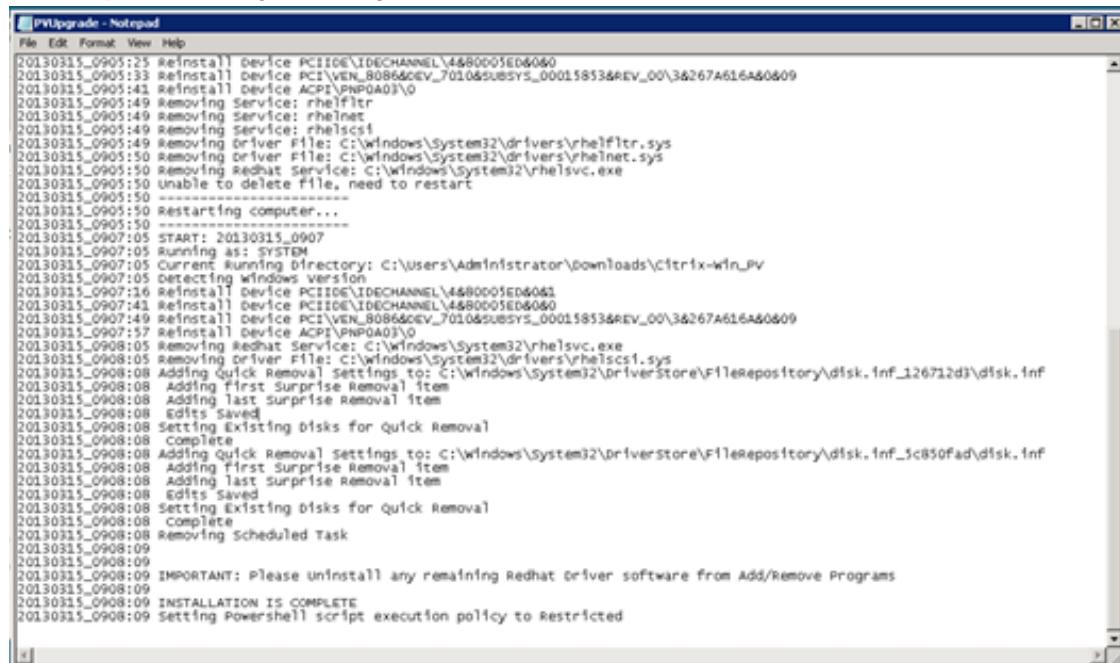

7. Check that the instance has rebooted and is ready to be used.
 - a. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
 - b. On the **Instances** page, select **Actions**, then **Monitor and troubleshoot**, and then choose **Get system log**.
 - c. The upgrade operations should have restarted the server 3 or 4 times. You can see this in the log file by the number of times Windows is Ready to use is displayed.

```

Upgrade your Citrix Xen guest agent service

If you are using Citrix PV drivers on Windows Server, you can upgrade the Citrix Xen guest agent service. This Windows service handles tasks such as shutdown and restart events from the API. You can run this upgrade package on any version of Windows Server, as long as the instance is running Citrix PV drivers.

Important

For Windows Server 2008 R2 and later, we recommend you upgrade to AWS PV drivers that include the Guest Agent update.

Before you start upgrading your drivers, make sure you back up your important information on the instance, or create an AMI from the instance. For more information about creating an AMI, see [Create a custom Windows AMI \(p. 151\)](#). If you create an AMI, make sure you do the following:

- Do not enable the Sysprep tool in the EC2Config service.
- Write down your password.
- Set your Ethernet adapter to DHCP.

To upgrade your Citrix Xen guest agent service

1. Connect to your instance and log in as the local administrator. For more information about connecting to your instance, see [Connect to your Windows instance \(p. 626\)](#).
2. On your instance, [download](#) the Citrix upgrade package.
3. Extract the contents of the upgrade package to a location of your choice.
4. Double-click the **Upgrade.bat** file. If you get a security warning, choose **Run**.
5. In the **Upgrade Drivers** dialog box, review the information and choose **Yes** if you are ready to start the upgrade.
6. When the upgrade is complete, the PVUpgrade.log file will open and contain the text UPGRADE IS COMPLETE.
7. Reboot your instance.

Troubleshoot PV drivers

The following are solutions to issues that you might encounter with older Amazon EC2 images and PV drivers.

Contents

- [Windows Server 2012 R2 loses network and storage connectivity after an instance reboot \(p. 791\)](#)
- [TCP offloading \(p. 795\)](#)
- [Time synchronization \(p. 796\)](#)
- [Workloads that leverage more than 20,000 disk IOPS experience degradation due to CPU bottlenecks \(p. 796\)](#)

Windows Server 2012 R2 loses network and storage connectivity after an instance reboot

Important

This issue occurs only with AMIs made available before September 2014.

Windows Server 2012 R2 Amazon Machine Images (AMIs) made available before September 10, 2014 can lose network and storage connectivity after an instance reboot. The error in the AWS Management Console system log states: "Difficulty detecting PV driver details for Console Output." The connectivity

loss is caused by the Plug and Play Cleanup feature. This feature scans for and disables inactive system devices every 30 days. The feature incorrectly identifies the EC2 network device as inactive and removes it from the system. When this happens, the instance loses network connectivity after a reboot.

For systems that you suspect could be affected by this issue, you can download and run an in-place driver upgrade. If you are unable to perform the in-place driver upgrade, you can run a helper script. The script determines if your instance is affected. If it is affected, and the Amazon EC2 network device has not been removed, the script disables the Plug and Play Cleanup scan. If the network device was removed, the script repairs the device, disables the Plug and Play Cleanup scan, and enables your instance to reboot with network connectivity enabled.

Contents

- [Choose how to fix problems \(p. 792\)](#)
- [Method 1 - Enhanced networking \(p. 792\)](#)
- [Method 2 - Registry configuration \(p. 793\)](#)
- [Run the remediation script \(p. 795\)](#)

Choose how to fix problems

There are two methods for restoring network and storage connectivity to an instance affected by this issue. Choose one of the following methods:

Method	Prerequisites	Procedure Overview
Method 1 - Enhanced networking	Enhanced networking is only available in a virtual private cloud (VPC) which requires a C3 instance type. If the server does not currently use the C3 instance type, then you must temporarily change it.	You change the server instance type to a C3 instance. Enhanced networking then enables you to connect to the affected instance and fix the problem. After you fix the problem, you change the instance back to the original instance type. This method is typically faster than Method 2 and less likely to result in user error. You will incur additional charges as long as the C3 instance is running.
Method 2 - Registry configuration	Ability to create or access a second server. Ability to change Registry settings.	You detach the root volume from the affected instance, attach it to a different instance, connect, and make changes in the Registry. You will incur additional charges as long as the additional server is running. This method is slower than Method 1, but this method has worked in situations where Method 1 failed to resolve the problem.

Method 1 - Enhanced networking

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.

3. Locate the affected instance. Select the instance and choose **Instance state**, and then choose **Stop instance**.

Warning

When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

4. After the instance is stopped, create a backup. Select the instance and choose **Actions**, then **Image and templates**, and then choose **Create image**.
5. Change the instance type to any C3 instance type.
6. Start the instance.
7. Connect to the instance using Remote Desktop and then download the AWS PV Drivers Upgrade package to the instance.
8. Extract the contents of the folder and run AWSPVDriverSetup.msi.

After running the MSI, the instance automatically reboots and then upgrades the drivers. The instance will not be available for up to 15 minutes.

9. After the upgrade is complete and the instance passes both health checks in the Amazon EC2 console, connect to the instance using Remote Desktop and verify that the new drivers were installed. In Device Manager, under **Storage Controllers**, locate **AWS PV Storage Host Adapter**. Verify that the driver version is the same as the latest version listed in the Driver Version History table. For more information, see [AWS PV driver package history \(p. 782\)](#).
10. Stop the instance and change the instance back to its original instance type.
11. Start the instance and resume normal use.

Method 2 - Registry configuration

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Locate the affected instance. Select the instance, choose **Instance state**, and then choose **Stop instance**.

Warning

When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

4. Choose **Launch instances** and create a temporary Windows Server 2008 or Windows Server 2012 instance in the same Availability Zone as the affected instance. Do not create a Windows Server 2012 R2 instance.

Important

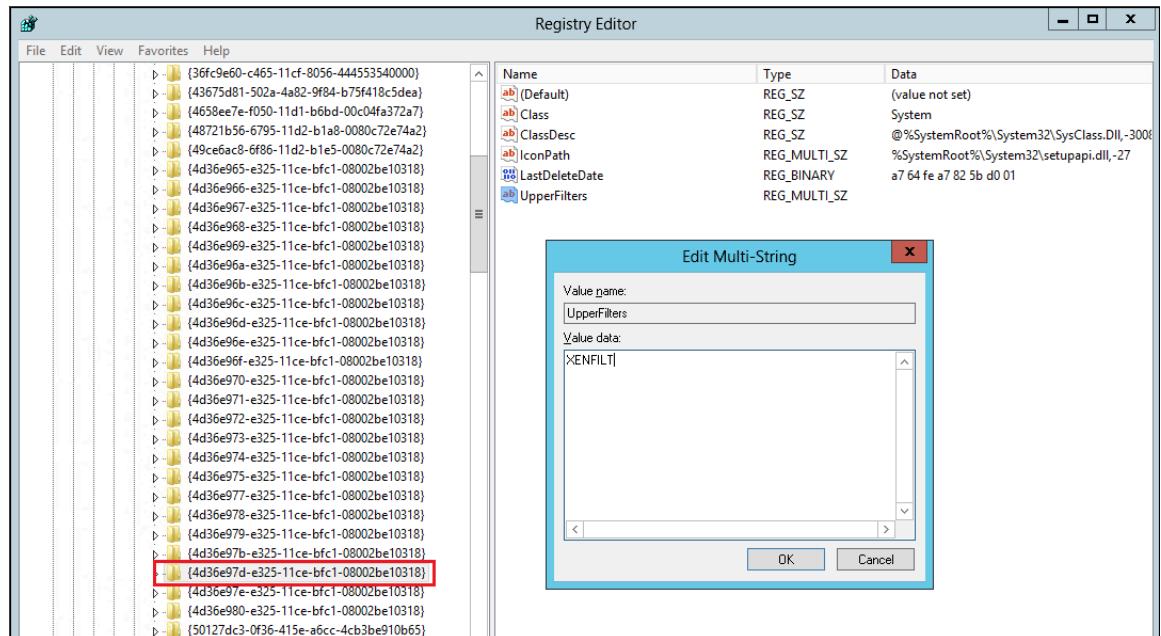

If you do not create the instance in the same Availability Zone as the affected instance you will not be able to attach the root volume of the affected instance to the new instance.

5. In the navigation pane, choose **Volumes**.
6. Locate the root volume of the affected instance. [Detach the volume \(p. 1752\)](#) and then [attach the volume \(p. 1729\)](#) to the temporary instance you created earlier. Attach it with the default device name (xvdf).
7. Use Remote Desktop to connect to the temporary instance, and then use the Disk Management utility to [make the volume available for use \(p. 1731\)](#).
8. On the temporary instance, open the **Run** dialog box, type **regedit**, and press Enter.
9. In the Registry Editor navigation pane, choose **HKEY_Local_Machine**, and then from the **File** menu choose **Load Hive**.
10. In the **Load Hive** dialog box, navigate to *Affected Volume\Windows\System32\config\System* and type a temporary name in the **Key Name** dialog box. For example, enter *OldSys*.
11. In the navigation pane of the Registry Editor, locate the following keys:

HKEY_LOCAL_MACHINE\your_temporary_key_name\ControlSet001\Control\Class\4d36e97d-e325-11ce-bfc1-08002be10318

HKEY_LOCAL_MACHINE\your_temporary_key_name\ControlSet001\Control\Class\4d36e96a-e325-11ce-bfc1-08002be10318

12. For each key, double-click **UpperFilters**, enter a value of XENFILT, and then choose **OK**.

13. Locate the following key:

HKEY_LOCAL_MACHINE\your_temporary_key_name\ControlSet001\Services\XENBUS\Parameters

14. Create a new string (REG_SZ) with the name ActiveDevice and the following value:

PCI\VEN_5853&DEV_0001&SUBSYS_00015853&REV_01

15. Locate the following key:

HKEY_LOCAL_MACHINE\your_temporary_key_name\ControlSet001\Services\XENBUS

16. Change the **Count** from 0 to 1.

17. Locate and delete the following keys:

HKEY_LOCAL_MACHINE\your_temporary_key_name\ControlSet001\Services\xenvbd\StartOverride

HKEY_LOCAL_MACHINE\your_temporary_key_name\ControlSet001\Services\xenfilt\StartOverride

18. In the Registry Editor navigation pane, choose the temporary key that you created when you first opened the Registry Editor.
19. From the **File** menu, choose **Unload Hive**.
20. In the Disk Management Utility, choose the drive you attached earlier, open the context (right-click) menu, and choose **Offline**.
21. In the Amazon EC2 console, detach the affected volume from the temporary instance and reattach it to your Windows Server 2012 R2 instance with the device name /dev/sda1. You must specify this device name to designate the volume as a root volume.

22. [Start](#) the instance.
23. Connect to the instance using Remote Desktop and then [download](#) the AWS PV Drivers Upgrade package to the instance.
24. Extract the contents of the folder and run AwSPVDriverSetup.msi.

After running the MSI, the instance automatically reboots and then upgrades the drivers. The instance will not be available for up to 15 minutes.
25. After the upgrade is complete and the instance passes both health checks in the Amazon EC2 console, connect to the instance using Remote Desktop and verify that the new drivers were installed. In Device Manager, under **Storage Controllers**, locate **AWS PV Storage Host Adapter**. Verify that the driver version is the same as the latest version listed in the Driver Version History table. For more information, see [AWS PV driver package history \(p. 782\)](#).
26. Delete or stop the temporary instance you created in this procedure.

Run the remediation script

If you are unable to perform an in-place driver upgrade or migrate to a newer instance you can run the remediation script to fix the problems caused by the Plug and Play Cleanup task.

To run the remediation script

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance for which you want to run the remediation script. Choose **Instance state**, and then choose **Stop instance**.

Warning

When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

4. After the instance is stopped, create a backup. Select the instance, choose **Actions**, then **Image and templates**, and then choose **Create image**.
5. Choose **Instance state**, and then choose **Start instance**.
6. Connect to the instance by using Remote Desktop and then [download](#) the RemediateDriverIssue.zip folder to the instance.
7. Extract the contents of the folder.
8. Run the remediation script according to the instructions in the Readme.txt file. The file is located in the folder where you extracted RemediateDriverIssue.zip.

TCP offloading

Important

This issue does not apply to instances running AWS PV or Intel network drivers.

By default, TCP offloading is enabled for the Citrix PV drivers in Windows AMIs. If you encounter transport-level errors or packet transmission errors (as visible on the Windows Performance Monitor)—for example, when you're running certain SQL workloads—you may need to disable this feature.

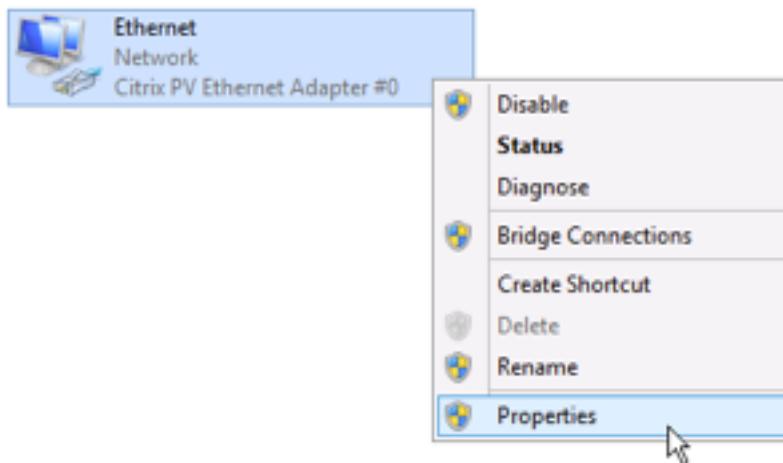

Warning

Disabling TCP offloading may reduce the network performance of your instance.

To disable TCP offloading for Windows Server 2012 and 2008

1. Connect to your instance and log in as the local administrator.
2. If you're using Windows Server 2012, press **Ctrl+Esc** to access the **Start** screen, and then choose **Control Panel**. If you're using Windows Server 2008, choose **Start** and select **Control Panel**.

3. Choose **Network and Internet**, then **Network and Sharing Center**.
4. Choose **Change adapter settings**.
5. Right-click **Citrix PV Ethernet Adapter #0** and select **Properties**.

6. In the **Local Area Connection Properties** dialog box, choose **Configure** to open the **Citrix PV Ethernet Adapter #0 Properties** dialog box.
7. On the **Advanced** tab, disable each of the properties, except for **Correct TCP/UDP Checksum Value**. To disable a property, select it from **Property** and choose **Disabled** from **Value**.
8. Choose **OK**.
9. Run the following commands from a Command Prompt window.

```
netsh int ip set global taskoffload=disabled
netsh int tcp set global chimney=disabled
netsh int tcp set global rss=disabled
netsh int tcp set global netdma=disabled
```

10. Reboot the instance.

Time synchronization

Prior to the release of the 2013.02.13 Windows AMI, the Citrix Xen guest agent could set the system time incorrectly. This can cause your DHCP lease to expire. If you have issues connecting to your instance, you might need to update the agent.

To determine whether you have the updated Citrix Xen guest agent, check whether the C:\Program Files\Citrix\XenGuestAgent.exe file is from March 2013. If the date on this file is earlier than that, update the Citrix Xen guest agent service. For more information, see [Upgrade your Citrix Xen guest agent service \(p. 791\)](#).

Workloads that leverage more than 20,000 disk IOPS experience degradation due to CPU bottlenecks

You can be affected by this issue if you are using Windows instances running AWS PV drivers that leverage more than 20,000 IOPS, and you experience bug check code 0x9E: USER_MODE_HEALTH_MONITOR.

Disk reads and writes (IOs) in the AWS PV drivers occur in two phases: **IO preparation** and **IO completion**. By default, the preparation phase runs on a single arbitrary core. The completion phase runs on core 0. The amount of computation required to process an IO varies based on its size and other properties. Some IOs use more computation in the preparation phase, and others in the completion phase. When an instance drives more than 20,000 IOPS, the preparation or completion phase may result

in a bottleneck, where the CPU upon which it runs is at 100% capacity. Whether or not the preparation or completion phase becomes a bottleneck depends on the properties of the IOs used by the application.

Starting with AWS PV drivers 8.4.0, the load of the preparation phase and the completion phase can be distributed across multiple cores, eliminating bottlenecks. Each application uses different IO properties. Therefore, applying one of the following configurations may raise, lower, or not impact the performance of your application. After you apply any of these configurations, monitor the application to verify that it is meeting your desired performance.

1. Prerequisites

Before you begin this troubleshooting procedure, verify the following prerequisites:

- Your instance uses AWS PV drivers version 8.4.0 or later. To upgrade, see [Upgrade PV drivers on Windows instances \(p. 786\)](#).
- You have RDP access to the instance. For steps to connect to your Windows instance using RDP, see [Connect to your Windows instance using RDP \(p. 627\)](#).
- You have administrator access on the instance.

2. Observe CPU load on your instance

You can use Windows Task Manager to view the load on each CPU to determine potential bottlenecks to disk IO.

1. Verify that your application is running and handling traffic similar to your production workload.
2. Connect to your instance using RDP.
3. Choose the **Start** menu on your instance.
4. Enter Task Manager in the **Start** menu to open Task Manager.
5. If Task Manager displays the Summary View, choose **More details** to expand the detailed view.
6. Choose the **Performance** tab.
7. Select **CPU** in the left pane.
8. Right-click on the graph in the main pane and select **Change graph to>Logical processors** to display each individual core.
9. Depending on how many cores are on your instance, you may see lines displaying CPU load over time, or you may just see a number.
 - If you see graphs displaying load over time, look for CPUs where the box is almost entirely shaded.
 - If you see a number on each core, look for cores that consistently show 95% or greater.

10Note whether core 0 or a different core is experiencing a heavy load.

3. Choose which configuration to apply

Configuration name	When to apply this configuration	Notes
Default configuration	Workload is driving less than 20,000 IOPS, or other configurations did not improve performance or stability.	For this configuration, IO occurs on a few cores, which may benefit smaller workloads by increasing cache locality and reducing context switching.
Allow driver to choose whether to distribute completion	Workload is driving more than 20,000 IOPS and moderate or high load is observed on core 0.	This configuration is recommended for all Xen instances using PV 8.4.0 or later and leveraging more than

Configuration name	When to apply this configuration	Notes
		20,000 IOPS, whether or not problems are encountered.
<u>Distribute both preparation and completion</u>	Workload is driving more than 20,000 IOPS, and either allowing the driver to choose the distribution did not improve performance, or a core other than 0 is experiencing a high load.	This configuration enables distribution of both IO preparation and IO completion.

Note

We recommend that you do not distribute IO preparation without also distributing IO completion (setting `DpcRedirection` without setting `NotifierDistributed`) because the completion phase is sensitive to overload by the preparation phase when the preparation phase is running in parallel.

Registry key values

- *NotifierDistributed*

Value 0 or not present — The completion phase will run on core 0.

Value 1 — The driver chooses to run the completion phase on core 0 or one additional core per attached disk.

Value 2 — The driver runs the completion phase on one additional core per attached disk.

- *DpcRedirection*

Value 0 or not present — The preparation phase will run on a single, arbitrary core.

Value 1 — The preparation phase is distributed across multiple cores.

Default configuration

Apply the default configuration with AWS PV driver versions prior to 8.4.0, or if performance or stability degradation is observed after applying one of the other configurations in this section.

1. Connect to your instance using RDP.
2. Open a new PowerShell command prompt as an administrator.
3. Run the following commands to remove the `NotifierDistributed` and `DpcRedirection` registry keys.

```
Remove-ItemProperty -Path HKLM:\System\CurrentControlSet\Services\xenvbd\Parameters -Name NotifierDistributed
```

```
Remove-ItemProperty -Path HKLM:\System\CurrentControlSet\Services\xenvbd\Parameters -Name DpcRedirection
```

4. Reboot your instance.

Allow driver to choose whether to distribute completion

Set `NotifierDistributed` registry key to allow the PV storage driver to choose whether or not to distribute IO completion.

1. Connect to your instance using RDP.
2. Open a new PowerShell command prompt as an administrator.
3. Run the following command to set the `NotifierDistributed` registry key.

```
Set-ItemProperty -Type DWORD -Path HKLM:\System\CurrentControlSet\Services\xenvbd
\Parameters -Value 0x00000001 -Name NotifierDistributed
```

4. Reboot your instance.

Distribute both preparation and completion

Set `NotifierDistributed` and `DpcRedirection` registry keys to always distribute both the preparation and completion phases.

1. Connect to your instance using RDP.
2. Open a new PowerShell command prompt as an administrator.
3. Run the following commands to set the `NotifierDistributed` and `DpcRedirection` registry keys.

```
Set-ItemProperty -Type DWORD -Path HKLM:\System\CurrentControlSet\Services\xenvbd
\Parameters -Value 0x00000002 -Name NotifierDistributed
```

```
Set-ItemProperty -Type DWORD -Path HKLM:\System\CurrentControlSet\Services\xenvbd
\Parameters -Value 0x00000001 -Name DpcRedirection
```

4. Reboot your instance.

AWS NVMe drivers for Windows instances

Amazon EBS volumes and instance store volumes are exposed as NVMe block devices on [Nitro-based instances \(p. 218\)](#). Windows Server 2012 R2 and later include an NVMe driver, [StorNVMe](#), that is provided by Microsoft. However, to achieve the full performance and features provided by Amazon EBS you must have the AWS NVMe driver installed when using an NVMe block device. The latest AWS Windows AMIs for Windows Server 2008 R2 and later contain the required AWS NVMe driver.

For more information about EBS and NVMe, see [Amazon EBS and NVMe on Windows instances \(p. 1939\)](#). For more information about SSD instance store and NVMe, see [SSD instance store volumes \(p. 2012\)](#).

Install or upgrade AWS NVMe drivers using PowerShell

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](#).

If you are not using the latest AWS Windows AMIs provided by Amazon, use the following procedure to install the current AWS NVMe driver. You should perform this update at a time when it is convenient to reboot your instance. Either the install script will reboot your instance or you must reboot it as the final step.

Prerequisites

PowerShell 3.0 or later

To download and install the latest AWS NVMe driver

1. We recommend that you create an AMI as a backup as follows, in case you need to roll back your changes.
 - a. When you stop an instance, the data on any instance store volumes is erased. Before you stop an instance, verify that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
 - b. In the navigation pane, choose **Instances**.
 - c. Select the instance that requires the driver upgrade, and choose **Instance state, Stop instance**.
 - d. After the instance is stopped, select the instance, choose **Actions**, then **Image and templates**, and then choose **Create image**.
 - e. Choose **Instance state, Start instance**.
2. Connect to your instance and log in as the local administrator.
3. Download and extract the drivers to your instance using one of the following options:
 - Using a browser:
 - a. [Download](https://s3.amazonaws.com/ec2-windows-drivers-downloads/NVMe/Latest/AWSNVMe.zip) the latest driver package to the instance.
 - b. Extract the zip archive.
 - Using PowerShell:

```
Invoke-WebRequest https://s3.amazonaws.com/ec2-windows-drivers-downloads/NVMe/Latest/AWSNVMe.zip -outfile $env:USERPROFILE\ nvme_driver.zip
Expand-Archive $env:UserProfile\ nvme_driver.zip -DestinationPath $env:UserProfile\ nvme_driver
```

4. Install the driver to your instance by running the `install.ps1` PowerShell script from the `nvme_driver` directory (`.\install.ps1`). If you get an error, make sure you are using PowerShell 3.0 or later.

`install.ps1` allows you to specify whether the `ebsnvme-id` tool should be installed with the driver. To install the `ebsnvme-id` tool, specify `InstallEBSNVMeIdTool` ‘Yes’. If you do not want to install the tool, specify `InstallEBSNVMeIdTool` ‘No’. If you do not specify `InstallEBSNVMeIdTool`, and the tool is already present at `C:\ProgramData\Amazon\Tools`, the package will upgrade the tool by default. If the tool is not present, `install.ps1` will not upgrade the tool by default. If you do not want to install the tool as part of the package, and want to install it later, you can download it from Amazon S3:

[Download](#) the latest `ebsnvme-id` tool.

5. If the installer does not reboot your instance, reboot the instance.

Install or upgrade AWS NVMe drivers with Distributor

You can use Distributor, a capability of AWS Systems Manager, to install the NVMe driver package one time or with scheduled updates.

1. For the instructions for how to install the NVMe driver package using Distributor, see the procedures in [Install or update packages](#) in the *Amazon EC2 Systems Manager User Guide*.
2. For **Document version**, select the AWSNVMe package.
3. To install the ebsnvme-id tool , specify {"SSM_InstallEBSNVMeIdTool": "Yes"} for **Additional Arguments**. If you do not want to install the tool, specify {"SSM_InstallEBSNVMeIdTool": "No"}.

If SSM_InstallEBSNVMeIdTool is not specified for **Additional Arguments**, and the tool is already present at C:\ProgramData\Amazon\Tools, the package will upgrade the tool by default. If the tool is not present, the package will not upgrade the tool by default. **Additional Arguments** must be formatted using valid JSON syntax. For examples of how to pass additional arguments for the aws configure package, see the [Amazon EC2 Systems Manager documentation](#). If you do not want to install the tool as part of the package, and want to install it later, you can download it from Amazon S3:

[Download](#) the latest ebsnvme-id tool.

4. If the installer does not reboot your instance, reboot the instance.

AWS NVMe driver version history

The following table shows the corresponding NVMe driver version to download for each Windows Server version on Amazon EC2.

Windows Server version	AWSNVMe driver version
Windows Server 2022	latest
Windows Server 2019	latest
Windows Server 2016	latest
Windows Server 2012 R2	latest
Windows Server 2012	latest
Windows Server 2008 R2	1.3.2 and earlier

The following table describes the released versions of the AWS NVMe driver.

Driver version	Details	Release date
1.4.2	Fixed a bug where the AWS NVMe driver did not support instance store volumes on D3 instances.	16 March 2023
1.4.1	Reports Namespace Preferred Write Granularity (NPGW) for EBS volumes that support this optional NVMe feature. For more information, see section 8.25, "Improving Performance through I/O Size and Alignment Adherence," in the NVMe Base Specification, version 1.4 .	20 May 2022
1.4.0	<ul style="list-style-type: none">• Added support for IOCTLs that allow applications to interact with NVMe devices. This support allows applications to get IdentifyController, IdentifyNamespace, and NameSpace list from the NVMe device. For more information, see Protocol-specific queries in the Microsoft documentation.	23 November 2021

Driver version	Details	Release date
	<ul style="list-style-type: none"> AWSNVMe 1.4.0 installation on Windows Server 2008 R2 will fail. AWSNVMe version 1.3.2 and earlier are supported on Windows Server 2008 R2. The 1.4.0 driver version and the latest ebsnvme-id tool (<code>ebsnvme-id.exe</code>) are combined in a single package. This combination allows you to install both driver and tool from a single package. For more details, see Install or upgrade AWS NVMe drivers using PowerShell (p. 799). Bug fixes and reliability improvements. 	
1.3.2	Fixed issue with modifying EBS volumes actively processing IO, which may result in data corruption. Customers who do not modify online EBS volumes (for example, resizing or changing type) are not impacted.	10 September 2019
1.3.1	Reliability Improvements.	21 May 2019
1.3.0	Device optimization improvements.	31 August 2018
1.2.0	Performance and reliability improvements for AWS NVMe devices on all supported instances, including bare metal instances.	13 June 2018
1.0.0	AWS NVMe driver for supported instance types running Windows Server.	12 February 2018

Subscribe to notifications

Amazon SNS can notify you when new versions of EC2 Windows Drivers are released. Use the following procedure to subscribe to these notifications.

To subscribe to EC2 notifications from the console

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must select this Region because the SNS notifications that you are subscribing to are in this Region.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. In the **Create subscription** dialog box, do the following:
 - a. For **TopicARN**, copy the following Amazon Resource Name (ARN):

```
arn:aws:sns:us-east-1:801119661308:ec2-windows-drivers
```
 - b. For **Protocol**, choose Email.
 - c. For **Endpoint**, type an email address that you can use to receive the notifications.
 - d. Choose **Create subscription**.
6. You'll receive a confirmation email. Open the email and follow the directions to complete your subscription.

Whenever new EC2 Windows drivers are released, we send notifications to subscribers. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

To unsubscribe from Amazon EC2 Windows driver notification

1. Open the Amazon SNS console at <https://console.aws.amazon.com/sns/v3/home>.
2. In the navigation pane, choose **Subscriptions**.
3. Select the check box for the subscription and then choose **Actions, Delete subscriptions**. When prompted for confirmation, choose **Delete**.

To subscribe to EC2 notifications using the AWS CLI

To subscribe to EC2 notifications with the AWS CLI, use the following command.

```
aws sns subscribe --topic-arn arn:aws:sns:us-east-1:801119661308:ec2-windows-drivers --  
protocol email --notification-endpoint YourUserName@YourDomainName.ext
```

To subscribe to EC2 notifications using AWS Tools for Windows PowerShell

To subscribe to EC2 notifications with AWS Tools for Windows PowerShell, use the following command.

```
Connect-SNSNotification -TopicArn 'arn:aws:sns:us-east-1:801119661308:ec2-windows-drivers'  
-Protocol email -Region us-east-1 -Endpoint 'YourUserName@YourDomainName.ext'
```

Optimize CPU options

Amazon EC2 instances support multithreading, which enables multiple threads to run concurrently on a single CPU core. Each thread is represented as a virtual CPU (vCPU) on the instance. An instance has a default number of CPU cores, which varies according to instance type. For example, an m5.xlarge instance type has two CPU cores and two threads per core by default—four vCPUs in total.

Note

Each vCPU is a thread of a CPU core, except for T2 instances and 64-bit ARM platforms such as instances powered by AWS Graviton2 processors and Apple Silicon Mac instances.

In most cases, there is an Amazon EC2 instance type that has a combination of memory and number of vCPUs to suit your workloads. However, you can specify the following CPU options to optimize your instance for specific workloads or business needs:

- **Number of CPU cores:** You can customize the number of CPU cores for the instance. You might do this to potentially optimize the licensing costs of your software with an instance that has sufficient amounts of RAM for memory-intensive workloads but fewer CPU cores.
- **Threads per core:** You can disable multithreading by specifying a single thread per CPU core. You might do this for certain workloads, such as high performance computing (HPC) workloads.

You can specify these CPU options during instance launch. There is no additional or reduced charge for specifying CPU options. You're charged the same as instances that are launched with default CPU options.

Contents

- [Rules for specifying CPU options \(p. 804\)](#)
- [CPU cores and threads per CPU core per instance type \(p. 804\)](#)
- [Specify CPU options for your instance \(p. 834\)](#)
- [View the CPU options for your instance \(p. 838\)](#)

Rules for specifying CPU options

To specify the CPU options for your instance, be aware of the following rules:

- You can't specify CPU options for bare metal instances.
- CPU options can only be specified during instance launch and cannot be modified after launch.
- When you launch an instance, you must specify both the number of CPU cores and threads per core in the request. For example requests, see [Specify CPU options for your instance \(p. 834\)](#).
- The number of vCPUs for the instance is the number of CPU cores multiplied by the threads per core. To specify a custom number of vCPUs, you must specify a valid number of CPU cores and threads per core for the instance type. You cannot exceed the default number of vCPUs for the instance. For more information, see [CPU cores and threads per CPU core per instance type \(p. 804\)](#).
- To disable multithreading, specify one thread per core.
- When you [change the instance type \(p. 344\)](#) of an existing instance, the CPU options automatically change to the default CPU options for the new instance type.
- The specified CPU options persist after you stop, start, or reboot an instance.

CPU cores and threads per CPU core per instance type

The following tables list the instance types that support specifying CPU options.

Contents

- [General purpose instances \(p. 804\)](#)
- [Compute optimized instances \(p. 814\)](#)
- [Memory optimized instances \(p. 819\)](#)
- [Storage optimized instances \(p. 830\)](#)
- [Accelerated computing instances \(p. 833\)](#)

General purpose instances

Instance type	Default vCPUs	Default CPU cores	Default threads per core	Valid CPU cores	Valid threads per core
m2.xlarge	2	2	1	1, 2	1
m2.2xlarge	4	4	1	1, 2, 3, 4	1
m2.4xlarge	8	8	1	1, 2, 3, 4, 5, 6, 7, 8	1
m3.large	2	1	2	1	1, 2
m3.xlarge	4	2	2	1, 2	1, 2
m3.2xlarge	8	4	2	1, 2, 3, 4	1, 2
m4.large	2	1	2	1	1, 2
m4.xlarge	4	2	2	1, 2	1, 2
m4.2xlarge	8	4	2	1, 2, 3, 4	1, 2

Specify CPU options for your instance

You can specify CPU options during instance launch.

The following examples describe how to specify the CPU options when using the launch instance wizard in the EC2 console and the [run-instances](#) AWS CLI command, and the create launch template page in the

EC2 console and the [create-launch-template](#) AWS CLI command. For EC2 Fleet or Spot Fleet, you must specify the CPU options in a launch template.

The following examples are for an `r4.4xlarge` instance type, which has the following [default values \(p. 819\)](#):

- Default CPU cores: 8
- Default threads per core: 2
- Default vCPUs: 16 ($8 * 2$)
- Valid number of CPU cores: 1, 2, 3, 4, 5, 6, 7, 8
- Valid number of threads per core: 1, 2

Disable multithreading

To disable multithreading, specify 1 thread per core.

New console

To disable multithreading during instance launch

1. Follow the [Quickly launch an instance \(p. 554\)](#) procedure and configure your instance as needed.
2. Expand **Advanced details**, and select the **Specify CPU options** check box.
3. For **Core count**, choose the number of required CPU cores. In this example, to specify the default CPU core count for an `r4.4xlarge` instance, choose 8.
4. To disable multithreading, for **Threads per core**, choose 1.
5. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an instance using the new launch instance wizard \(p. 552\)](#).

Old console

To disable multithreading during instance launch

1. Follow the [Launch an instance using the old launch instance wizard \(p. 561\)](#) procedure.
2. On the **Configure Instance Details** page, for **CPU options**, choose **Specify CPU options**.
3. For **Core count**, choose the number of required CPU cores. In this example, to specify the default CPU core count for an `r4.4xlarge` instance, choose 8.
4. To disable multithreading, for **Threads per core**, choose 1.
5. Continue as prompted by the wizard. When you've finished reviewing your options on the **Review Instance Launch** page, choose **Launch**. For more information, see [Launch an instance using the old launch instance wizard \(p. 561\)](#).

AWS CLI

To disable multithreading during instance launch

Use the [run-instances](#) AWS CLI command and specify a value of 1 for `ThreadsPerCore` for the `--cpu-options` parameter. For `CoreCount`, specify the number of CPU cores. In this example, to specify the default CPU core count for an `r4.4xlarge` instance, specify a value of 8.

```
aws ec2 run-instances \
--image-id ami-1a2b3c4d \
--instance-type r4.4xlarge \
```

```
--cpu-options "CoreCount=8,ThreadsPerCore=1" \
--key-name MyKeyPair
```

Specify a custom number of vCPUs at launch

You can customize the number of CPU cores and threads per core for the instance.

The following example launches an `r4.4xlarge` instance with six vCPUs.

New console

To specify a custom number of vCPUs during instance launch

1. Follow the [Quickly launch an instance \(p. 554\)](#) procedure and configure your instance as needed.
2. Expand **Advanced details**, and select the **Specify CPU options** check box.
3. To get 6 vCPUs, specify 3 CPU cores and 2 threads per core, as follows:
 - For **Core count**, choose **3**.
 - For **Threads per core**, choose **2**.
4. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an instance using the new launch instance wizard \(p. 552\)](#).

Old console

To specify a custom number of vCPUs during instance launch

1. Follow the [Launch an instance using the old launch instance wizard \(p. 561\)](#) procedure.
2. On the **Configure Instance Details** page, for **CPU options**, choose **Specify CPU options**.
3. To get 6 vCPUs, specify 3 CPU cores and 2 threads per core, as follows:
 - For **Core count**, choose **3**.
 - For **Threads per core**, choose **2**.
4. Continue as prompted by the wizard. When you've finished reviewing your options on the **Review Instance Launch** page, choose **Launch**. For more information, see [Launch an instance using the old launch instance wizard \(p. 561\)](#).

AWS CLI

To specify a custom number of vCPUs during instance launch

Use the `run-instances` AWS CLI command and specify the number of CPU cores and number of threads in the `--cpu-options` parameter. You can specify 3 CPU cores and 2 threads per core to get 6 vCPUs.

```
aws ec2 run-instances \
--image-id ami-1a2b3c4d \
--instance-type r4.4xlarge \
--cpu-options "CoreCount=3,ThreadsPerCore=2" \
--key-name MyKeyPair
```

Alternatively, specify 6 CPU cores and 1 thread per core (disable multithreading) to get 6 vCPUs:

```
aws ec2 run-instances \
```

```
--image-id ami-1a2b3c4d \
--instance-type r4.4xlarge \
--cpu-options "CoreCount=6,ThreadsPerCore=1" \
--key-name MyKeyPair
```

Specify a custom number of vCPUs in a launch template

You can customize the number of CPU cores and threads per core for the instance in a launch template.

The following example creates a launch template that specifies the configuration for an `r4.4xlarge` instance with 6 vCPUs.

Console

To specify a custom number of vCPUs in a launch template

1. Follow the [Create a new launch template using parameters you define \(p. 570\)](#) procedure and configure your launch template as needed.
2. Expand **Advanced details**, and select the **Specify CPU options** check box.
3. To get 6 vCPUs, specify 3 CPU cores and 2 threads per core, as follows:
 - For **Core count**, choose **3**.
 - For **Threads per core**, choose **2**.
4. In the **Summary** panel, review your instance configuration, and then choose **Create launch template**. For more information, see [Launch an instance from a launch template \(p. 567\)](#).

AWS CLI

To specify a custom number of vCPUs in a launch template

Use the [create-launch-template](#) AWS CLI command and specify the number of CPU cores and number of threads in the `CpuOptions` parameter. You can specify 3 CPU cores and 2 threads per core to get 6 vCPUs.

```
aws ec2 create-launch-template \
--launch-template-name TemplateForCPUOptions \
--version-description CPUOptionsVersion1 \
--launch-template-data file://template-data.json
```

The following is an example JSON file that contains the launch template data, which includes the CPU options, for the instance configuration for this example.

```
{
    "NetworkInterfaces": [
        {
            "AssociatePublicIpAddress": true,
            "DeviceIndex": 0,
            "Ipv6AddressCount": 1,
            "SubnetId": "subnet-7b16de0c"
        }
    ],
    "ImageId": "ami-8c1be5f6",
    "InstanceType": "r4.4xlarge",
    "TagSpecifications": [
        {
            "ResourceType": "instance",
            "Tags": [
                {
                    "Key": "Name",
                    "Value": "webserver"
                }
            ]
        }
    ]
}
```

```
        }],
    "CpuOptions": {
        "CoreCount":3,
        "ThreadsPerCore":2
    }
}
```

Alternatively, specify 6 CPU cores and 1 thread per core (disable multithreading) to get 6 vCPUs:

```
{
    "NetworkInterfaces": [
        {
            "AssociatePublicIpAddress": true,
            "DeviceIndex": 0,
            "Ipv6AddressCount": 1,
            "SubnetId": "subnet-7b16de0c"
        }
    ],
    "ImageId": "ami-8c1be5f6",
    "InstanceType": "r4.4xlarge",
    "TagSpecifications": [
        {
            "ResourceType": "instance",
            "Tags": [
                {
                    "Key": "Name",
                    "Value": "webserver"
                }
            ]
        }
    ],
    "CpuOptions": {
        "CoreCount":6,
        "ThreadsPerCore":1
    }
}
```

View the CPU options for your instance

You can view the CPU options for an existing instance in the Amazon EC2 console or by describing the instance using the AWS CLI.

Console

To view the CPU options for an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the left navigation pane, choose **Instances** and select the instance.
3. On the **Details** tab, under **Host and placement group**, find **Number of vCPUs**.

AWS CLI

To view the CPU options for an instance (AWS CLI)

Use the [describe-instances](#) command.

```
aws ec2 describe-instances --instance-ids i-123456789abcde123
```

```
...
    "Instances": [
        {
            "Monitoring": {
                "State": "disabled"
            }
        }
    ]
}
```

```
        },
        "PublicDnsName": "ec2-198-51-100-5.eu-central-1.compute.amazonaws.com",
        "State": {
            "Code": 16,
            "Name": "running"
        },
        "EbsOptimized": false,
        "LaunchTime": "2018-05-08T13:40:33.000Z",
        "PublicIpAddress": "198.51.100.5",
        "PrivateIpAddress": "172.31.2.206",
        "ProductCodes": [],
        "VpcId": "vpc-1a2b3c4d",
        "CpuOptions": {
            "CoreCount": 34,
            "ThreadsPerCore": 1
        },
        "StateTransitionReason": "",
        ...
    }
...
]
```

In the output that's returned, the `CoreCount` field indicates the number of cores for the instance. The `ThreadsPerCore` field indicates the number of threads per core.

Alternatively, connect to your instance and use Task Manager to view the CPU information for your instance.

You can use AWS Config to record, assess, audit, and evaluate configuration changes for instances, including terminated instances. For more information, see [Getting Started with AWS Config](#) in the *AWS Config Developer Guide*.

Set the time for a Windows instance

A consistent and accurate time reference is crucial for many server tasks and processes. Most system logs include a time stamp that you can use to determine when problems occur and in what order the events take place. If you use the AWS CLI or an AWS SDK to make requests from your instance, these tools sign requests on your behalf. If the date and time of your instance are not set correctly, the date in the signature may not match the date of the request, and AWS rejects the request.

Amazon provides the Amazon Time Sync Service, which is accessible from all EC2 instances, and is also used by other AWS services. This service uses a fleet of satellite-connected and atomic reference clocks in each Region to deliver accurate current time readings of the Coordinated Universal Time (UTC) global standard through Network Time Protocol (NTP). The Amazon Time Sync Service automatically smooths any leap seconds that are added to UTC.

The Amazon Time Sync Service is available through NTP at the 169.254.169.123 IPv4 address or the fd00:ec2::123 IPv6 address for any instance running in a VPC. Your instance does not require access to the internet, and you do not have to configure your security group rules or your network ACL rules to allow access. The latest versions of AWS Windows AMIs synchronize with the Amazon Time Sync Service by default.

Note

The examples in this section use the IPv4 address of the Amazon Time Sync Service: 169.254.169.123. If you are retrieving time for EC2 instances over the IPv6 address, ensure that you use the IPv6 address instead: fd00:ec2::123. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 218\)](#).

Should I use UTC for my instances?

We recommend that you use Coordinated Universal Time (UTC) for your instances to avoid human error and to facilitate synchronization across your CloudWatch Logs, Metrics, local logs, and other services. You can, however, choose to use a different time zone to better suit your requirements.

When you use local timezones rather than UTC, make sure that you account for aspects such as daylight savings time (when applicable) for automation, code, scheduled jobs, troubleshooting activities (correlating logs), and more.

Use the following procedures to configure the Amazon Time Sync Service on your instance from the command prompt. Alternatively, you can use external NTP sources. For more information about NTP and public time sources, see <http://www.ntp.org/>. An instance must have access to the internet for the external NTP time sources to work.

For Linux instances, see [Set the time for your Linux instance](#).

Contents

- [Change the time zone \(p. 840\)](#)
- [Configure network time protocol \(NTP\) \(p. 841\)](#)
- [Default network time protocol \(NTP\) settings for Amazon Windows AMIs \(p. 842\)](#)
- [Amazon Time Sync Public NTP \(p. 843\)](#)
- [Configure time settings for Windows Server 2008 and later \(p. 843\)](#)
- [Related resources \(p. 844\)](#)

Change the time zone

Windows instances are set to the UTC time zone by default. You can change the time to correspond to your local time zone or a time zone for another part of your network.

To change the time zone on an instance

1. From your instance, open a Command Prompt window.
2. Identify the time zone to use on the instance. To get a list of time zones, use the following command:

```
tzutil /l
```

This command returns a list of all available time zones, using the following format:

```
display name  
time zone ID
```

3. Locate the time zone ID to assign to the instance.
4. Assign to an alternate time zone by using the following command:

```
tzutil /s "Pacific Standard Time"
```

The new time zone should take effect immediately.

Note

You can assign the recommended UTC time zone by using the following command:

```
tzutil /s "UTC"
```

To configure Amazon Time Sync Public NTP for Microsoft Windows

For a backup to the Amazon Time Sync link-local service, and to connect resources outside of Amazon EC2 to the Amazon Time Sync Service, you can use the Amazon Time Sync Public NTP pool located at `time.aws.com`. Amazon Time Sync Public NTP, like the Amazon Time Sync service, automatically smooths any leap seconds that are added to UTC. The Amazon Time Sync Service Public NTP is supported globally by our fleet of satellite-connected and atomic reference clocks in each AWS Region. See [Configuring Clients to Amazon Time Sync Public NTP](#) for configuration instructions.

1. Open the **Control Panel**.
2. Choose the **Date and Time** icon.
3. Choose the **Internet Timetab**. This will not be available if your PC is part of a domain. In that case, it will synchronize time with the domain controller. You can configure the controller to use Amazon Time Sync Public NTP.
4. Choose **Change settings**.
5. Select the check box for **Synchronize with an Internet time server**.
6. Next to **Server**, enter **time.aws.com**.

To configure Amazon Time Sync Public NTP for Windows Server

- Follow [Microsoft's instructions](#) to update your registry.

Configure network time protocol (NTP)

Amazon provides the Amazon Time Sync Service, which is accessible from all EC2 instances, and is also used by other AWS services. We recommend that you configure your instance to use the Amazon Time Sync Service. This service uses a fleet of satellite-connected and atomic reference clocks in each AWS Region to deliver accurate current time readings of the Coordinated Universal Time (UTC) global standard. The Amazon Time Sync Service automatically smooths any leap seconds that are added to UTC. This service is available at the 169.254.169.123 IPv4 address or the fd00:ec2::123 IPv6 address for any instance running in a VPC, and your instance does not require internet access to use it. Starting with the August 2018 release, Windows AMIs use the Amazon Time Sync Service by default.

To verify the NTP configuration

1. From your instance, open a Command Prompt window.
2. Get the current NTP configuration by typing the following command:

```
w32tm /query /configuration
```

This command returns the current configuration settings for the Windows instance.

3. (Optional) Get the status of the current configuration by typing the following command:

```
w32tm /query /status
```

This command returns information such as the last time the instance synced with the NTP server and the poll interval.

To change the NTP server to use the Amazon Time Sync Service

1. From the Command Prompt window, run the following command:

```
w32tm /config /manualpeerlist:169.254.169.123 /syncfromflags:manual /update
```

- Verify your new settings by using the following command:

```
w32tm /query /configuration
```

In the output that's returned, verify that NtpServer displays the 169.254.169.123 IP address.

You can change the instance to use a different set of NTP servers if required. For example, if you have Windows instances that do not have internet access, you can configure them to use an NTP server located within your private network. If your instance is within a domain, you should change the settings to use the domain controllers as the time source to avoid time skew. The security group of your instance must be configured to allow outbound UDP traffic on port 123 (NTP).

To change the NTP servers

- From the Command Prompt window, run the following command:

```
w32tm /config /manualpeerlist:"NTP servers" /syncfromflags:manual /update
```

Where *NTP servers* is a space-delimited list of NTP servers for the instance to use.

- Verify your new settings by using the following command:

```
w32tm /query /configuration
```

Default network time protocol (NTP) settings for Amazon Windows AMIs

Amazon Machine Images (AMIs) generally adhere to the out-of-the-box defaults except in cases where changes are required to function on EC2 infrastructure. The following settings have been determined to work well in a virtual environment, as well as to keep any clock drift to within one second of accuracy:

- Update Interval** – governs how frequently the time service will adjust system time towards accuracy. AWS configures the update interval to occur once every two minutes.
- NTP Server** – starting with the August 2018 release, AMIs will now use the Amazon Time Sync Service by default. This time service is accessible from any EC2 Region at the 169.254.169.123 endpoint. Additionally, the 0x9 flag indicates that the time service is acting as a client, and to use SpecialPollInterval to determine how frequently to check in with the configured time server.
- Type** – "NTP" means that the service acts as a standalone NTP client instead of acting as part of a domain.
- Enabled and InputProvider** – the time service is enabled and provides time to the operating system.
- Special Poll Interval** – checks against the configured NTP Server every 900 seconds, or 15 minutes.

Registry Path	Key Name	Data
HKLM:\System\CurrentControlSet\services\w32time\Config	UpdateInterval	120

Registry Path	Key Name	Data
HKLM:\System\CurrentControlSet\services\w32time\Parameters	NtpServer	169.254.169.123,0x9
HKLM:\System\CurrentControlSet\services\w32time\Parameters	Type	NTP
HKLM:\System\CurrentControlSet\services\w32time\TimeProviders\NtpClient	Enabled	1
HKLM:\System\CurrentControlSet\services\w32time\TimeProviders\NtpClient	InputProvider	1
HKLM:\System\CurrentControlSet\services\w32time\TimeProviders\NtpClient	SpecialPollInterval	900

Amazon Time Sync Public NTP

To configure Amazon Time Sync Public NTP for Microsoft Windows

For a backup to the Amazon Time Sync link-local service, and to connect resources outside of Amazon EC2 to the Amazon Time Sync Service, you can use the Amazon Time Sync Public NTP pool located at `time.aws.com`. Amazon Time Sync Public NTP, like the Amazon Time Sync service, automatically smooths any leap seconds that are added to UTC. The Amazon Time Sync Service Public NTP is supported globally by our fleet of satellite-connected and atomic reference clocks in each AWS Region. See [Configuring Clients to Amazon Time Sync Public NTP](#) for configuration instructions.

1. Open the **Control Panel**.
2. Choose the **Date and Time** icon.
3. Choose the **Internet Time** tab. This will not be available if your PC is part of a domain. In that case, it will synchronize time with the domain controller. You can configure the controller to use Amazon Time Sync Public NTP.
4. Choose **Change settings**.
5. Select the check box for **Synchronize with an Internet time server**.
6. Next to **Server**, enter `time.aws.com`.

To configure Amazon Time Sync Public NTP for Windows Server

- Follow [Microsoft's instructions](#) to update your registry.

Configure time settings for Windows Server 2008 and later

When you change the time on a Windows instance, you must ensure that the time persists through system restarts. Otherwise, when the instance restarts, it reverts back to using UTC time. For Windows

Server 2008 and later, you can persist your time setting by adding a **RealTimeIsUniversal** registry key. This key is set by default on all current generation instances. To verify whether the **RealTimeIsUniversal** registry key is set, see Step 4 in the following procedure. If the key is not set, follow the these steps from the beginning.

To set the RealTimeIsUniversal registry key

1. From the instance, open a Command Prompt window.
 2. Use the following command to add the registry key:

```
reg add "HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\TimeZoneInformation" /v RealTimeIsUniversal /d 1 /t REG_DWORD /f
```

- If you are using a Windows Server 2008 AMI (*not* Windows Server 2008 R2) that was created before February 22, 2013, we recommend updating to the latest AWS Windows AMI. If you are using an AMI running Windows Server 2008 R2 (*not* Windows Server 2008), you must verify that the Microsoft hotfix [KB2922223](#) is installed. If this hotfix is not installed, we recommend updating to the latest AWS Windows AMI.
 - (Optional) Verify that the instance saved the key successfully using the following command:

```
reg query "HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\TimeZoneInformation" /s
```

Related resources

For more information about how the Windows operating system coordinates and manages time, including the addition of a leap second, see the following documentation:

- [How the Windows Time Service Works](#) (Microsoft)
 - [W32tm](#) (Microsoft)
 - [How the Windows Time service treats a leap second](#) (Microsoft)
 - [The story around Leap Seconds and Windows: It's likely not Y2K](#) (Microsoft)

Set the password for a Windows instance

When you connect to a Windows instance, you must specify a user account and password that has permission to access the instance. The first time that you connect to an instance, you are prompted to specify the Administrator account and the default password.

With AWS Windows AMIs for Windows Server 2012 R2 and earlier, the [EC2Config service \(p. 753\)](#) generates the default password. With AWS Windows AMIs for Windows Server 2016 and 2019, [EC2Launch \(p. 743\)](#) generates the default password. With AWS Windows AMIs for Windows Server 2022 and later, [EC2Launch v2 \(p. 692\)](#) generates the default password.

Note

With Windows Server 2016 and later, `Password never expires` is disabled for the local administrator. With Windows Server 2012 R2 and earlier, `Password never expires` is enabled for the local administrator.

Change the Administrator password after connecting

When you connect to an instance the first time, we recommend that you change the Administrator password from its default value. Use the following procedure to change the Administrator password for a Windows instance.

Important

Store the new password in a safe place. You won't be able to retrieve the new password using the Amazon EC2 console. The console can only retrieve the default password. If you attempt to connect to the instance using the default password after changing it, you'll get a "Your credentials did not work" error.

To change the local Administrator password

1. Connect to the instance and open a command prompt.
2. Run the following command. If your new password includes special characters, enclose the password in double quotes.

```
net user Administrator "new_password"
```

3. Store the new password in a safe place.

Change a lost or expired password

If you lose your password or it expires, you can generate a new password. For password reset procedures, see [Reset a lost or expired Windows administrator password \(p. 2134\)](#).

Add Windows components using installation media

Windows Server operating systems include many optional components. Including all optional components in each Amazon EC2 Windows Server AMI is not practical. Instead, we provide you with installation media EBS snapshots that have the necessary files to configure or install components on your Windows instance.

To access and install the optional components, you must find the correct EBS snapshot for your version of Windows Server, create a volume from the snapshot, and attach the volume to your instance.

Before you begin

Use the AWS Management Console or a command line tool to get the instance ID and Availability Zone of your instance. You must create your EBS volume in the same Availability Zone as your instance.

Add Windows components using the console

Use the following procedure to use the AWS Management Console to add Windows components to your instance.

To add Windows components to your instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Snapshots**.
3. From the **Filter** bar, choose **Public snapshots**.
4. Add the **Owner Alias** filter and choose **amazon**.
5. Add the **Description** filter and enter **Windows**.
6. Press Enter
7. Select the snapshot that matches your system architecture and language preference. For example, select **Windows 2019 English Installation Media** if your instance is running Windows Server 2019.
8. Choose **Actions, Create volume from snapshot**.
9. For **Availability Zone**, select the Availability Zone that matches your Windows instance. Choose **Add tag** and enter **Name** for the tag key and a descriptive name for the tag value. Choose **Create volume**.
10. In the **Successfully created volume** message (green banner), choose the volume that you just created.
11. Choose **Actions, Attach volume**.
12. From **Instance**, select the instance ID.
13. For **Device name**, enter the name of the device for the attachment. If you need help with the device name, see [Device names on Windows instances \(p. 2024\)](#).
14. Choose **Attach volume**.
15. Connect to your instance and make the volume available. For more information, see [Make an Amazon EBS volume available for use on Windows \(p. 1731\)](#).

Important

Do not initialize the volume.

16. Open **Control Panel, Programs and Features**. Choose **Turn Windows features on or off**. If you are prompted for installation media, specify the EBS volume with the installation media.
17. (Optional) When you are finished with the installation media, you can detach the volume. After you detach the volume, you can delete it. For more information, see [Detach an Amazon EBS volume from a Windows instance \(p. 1752\)](#) and [Delete an Amazon EBS volume \(p. 1755\)](#).

Add Windows components using the Tools for Windows PowerShell

Use the following procedure to use the Tools for Windows PowerShell to add Windows components to your instance.

To add Windows components to your instance using the Tools for Windows PowerShell

1. Use the [Get-EC2Snapshot](#) cmdlet with the Owner and description filters to get a list of the available installation media snapshots.

```
PS C:\> Get-EC2Snapshot -Owner amazon -Filter @{ Name="description"; Values="Windows*" }
```

2. In the output, note the ID of the snapshot that matches your system architecture and language preference. For example:

```
...
DataEncryptionKeyId : 
Description          : Windows 2019 English Installation Media
```

```
Encrypted      : False
KmsKeyId       :
OwnerAlias     : amazon
OwnerId        : 123456789012
Progress       : 100%
SnapshotId    : snap-22da283e
StartTime      : 10/25/2019 8:00:47 PM
State          : completed
StateMessage   :
Tags           : {}
VolumeId       : vol-be5eafcb
VolumeSize     : 6
...
```

3. Use the [New-EC2Volume](#) cmdlet to create a volume from the snapshot. Specify the same Availability Zone as your instance.

```
PS C:\> New-EC2Volume -AvailabilityZone us-east-1a -VolumeType gp2 -
SnapshotId snap-22da283e
```

4. In the output, note the volume ID.

```
Attachments    : {}
AvailabilityZone : us-east-1a
CreateTime     : 4/18/2017 10:50:25 AM
Encrypted      : False
Iops           : 100
KmsKeyId       :
Size           : 6
SnapshotId    : snap-22da283e
State          : creating
Tags           : {}
VolumeId       : vol-06aa9e1fbf8b82ed1
VolumeType     : gp2
```

5. Use the [Add-EC2Volume](#) cmdlet to attach the volume to your instance.

```
PS C:\> Add-EC2Volume -InstanceId i-087711ddaf98f9489 -VolumeId vol-06aa9e1fbf8b82ed1 -
Device xvh
```

6. Connect to your instance and make the volume available. For more information, see [Make an Amazon EBS volume available for use on Windows \(p. 1731\)](#).

Important

Do not initialize the volume.

7. Open **Control Panel, Programs and Features**. Choose **Turn Windows features on or off**. If you are prompted for installation media, specify the EBS volume with the installation media.
8. (Optional) When you are finished with the installation media, use the [Dismount-EC2Volume](#) cmdlet to detach the volume from your instance. After you detach the volume, you can use the [Remove-EC2Volume](#) cmdlet to delete the volume.

Add Windows components using the AWS CLI

Use the following procedure to use the AWS CLI to add Windows components to your instance.

To add Windows components to your instance using the AWS CLI

1. Use the [describe-snapshots](#) command with the owner-ids parameter and description filter to get a list of the available installation media snapshots.

```
aws ec2 describe-snapshots --owner-ids amazon --filters  
Name=description,Values=Windows*
```

2. In the output, note the ID of the snapshot that matches your system architecture and language preference. For example:

```
{  
    "Snapshots": [  
        ...  
        {  
            "OwnerAlias": "amazon",  
            "Description": "Windows 2019 English Installation Media",  
            "Encrypted": false,  
            "VolumeId": "vol-be5eafcb",  
            "State": "completed",  
            "VolumeSize": 6,  
            "Progress": "100%",  
            "StartTime": "2019-10-25T20:00:47.000Z",  
            "SnapshotId": "snap-22da283e",  
            "OwnerId": "123456789012"  
        },  
        ...  
    ]  
}
```

3. Use the [create-volume](#) command to create a volume from the snapshot. Specify the same Availability Zone as your instance.

```
aws ec2 create-volume --snapshot-id snap-22da283e --volume-type gp2 --availability-zone us-east-1a
```

4. In the output, note the volume ID.

```
{  
    "AvailabilityZone": "us-east-1a",  
    "Encrypted": false,  
    "VolumeType": "gp2",  
    "VolumeId": "vol-0c98b37f30bcbe290",  
    "State": "creating",  
    "Iops": 100,  
    "SnapshotId": "snap-22da283e",  
    "CreateTime": "2017-04-18T10:33:10.940Z",  
    "Size": 6  
}
```

5. Use the [attach-volume](#) command to attach the volume to your instance.

```
aws ec2 attach-volume --volume-id vol-0c98b37f30bcbe290 --instance-id i-01474ef662b89480 --device xvdf
```

6. Connect to your instance and make the volume available. For more information, see [Make an Amazon EBS volume available for use on Windows \(p. 1731\)](#).

Important

Do not initialize the volume.

7. Open **Control Panel, Programs and Features**. Choose **Turn Windows features on or off**. If you are prompted for installation media, specify the EBS volume with the installation media.
8. (Optional) When you are finished with the installation media, use the [detach-volume](#) command to detach the volume from your instance. After you detach the volume, you can use the [delete-volume](#) command to delete the volume.

Configure a secondary private IPv4 address for your Windows instance

You can specify multiple private IPv4 addresses for your instances. After you assign a secondary private IPv4 address to an instance, you must configure the operating system on the instance to recognize the secondary private IPv4 address.

Configuring the operating system on a Windows instance to recognize a secondary private IPv4 address requires the following:

Topics

- [Prerequisite steps \(p. 849\)](#)
- [Step 1: Configure static IP addressing on your instance \(p. 849\)](#)
- [Step 2: Configure a secondary private IP address for your instance \(p. 851\)](#)
- [Step 3: Configure applications to Use the secondary private IP address \(p. 852\)](#)

Note

These instructions are based on Windows Server 2008 R2. The implementation of these steps may vary based on the operating system of the Windows instance.

Before you begin

As a best practice, launch your Windows instances using the latest AMIs. If you are using an older Windows AMI, ensure that it has the Microsoft hot fix referenced in <http://support.microsoft.com/kb/2582281>.

Prerequisite steps

1. Assign the secondary private IPv4 address to the network interface for the instance. You can assign the secondary private IPv4 address when you launch the instance, or after the instance is running. For more information, see [Assign a secondary private IPv4 address \(p. 1243\)](#).
2. Allocate an Elastic IP address and associate it with the secondary private IPv4 address. For more information, see [Allocate an Elastic IP address \(p. 1270\)](#) and [Associate an Elastic IP address with the secondary private IPv4 address \(p. 1245\)](#).

Step 1: Configure static IP addressing on your instance

To enable your Windows instance to use multiple IP addresses, you must configure your instance to use static IP addressing rather than a DHCP server.

Important

When you configure static IP addressing on your instance, the IP address must match exactly what is shown in the console, CLI, or API. If you enter these IP addresses incorrectly, the instance could become unreachable.

To configure static IP addressing on a Windows instance

1. Connect to your instance.
2. Find the IP address, subnet mask, and default gateway addresses for the instance by performing the following steps:
 - At a Command Prompt window, run the following command:

```
ipconfig /all
```

Review the following section in your output, and note the **IPv4 Address**, **Subnet Mask**, **Default Gateway**, and **DNS Servers** values for the network interface.

Ethernet adapter Local Area Connection:

```
Connection-specific DNS Suffix . :  
Description . . . . . :  
Physical Address . . . . . :  
DHCP Enabled. . . . . :  
Autoconfiguration Enabled . . . . . :  
IPv4 Address. . . . . : 10.0.0.131  
Subnet Mask . . . . . : 255.255.255.0  
Default Gateway . . . . . : 10.0.0.1  
DNS Servers . . . . . : 10.1.1.10  
10.1.1.20
```

3. Open the **Network and Sharing Center** by running the following command:

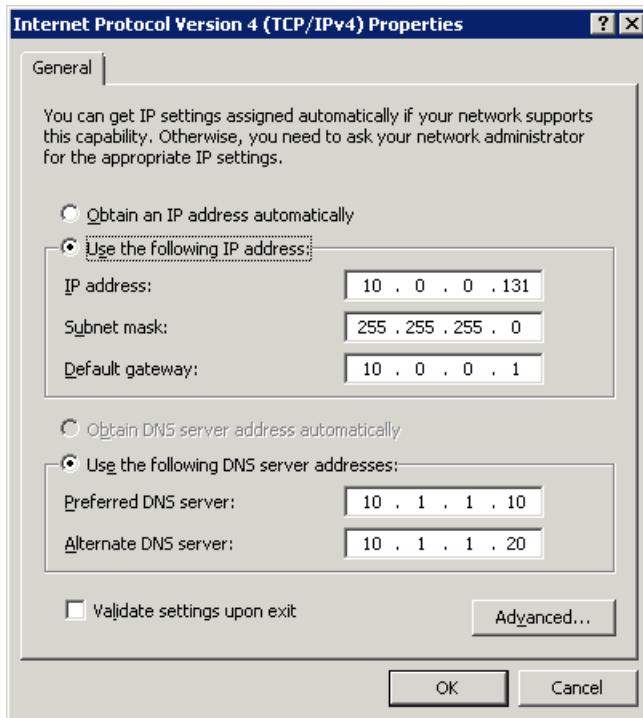

```
%SystemRoot%\system32\control.exe ncpa.cpl
```

4. Open the context (right-click) menu for the network interface (Local Area Connection) and choose **Properties**.
5. Choose **Internet Protocol Version 4 (TCP/IPv4), Properties**.
6. In the **Internet Protocol Version 4 (TCP/IPv4) Properties** dialog box, choose **Use the following IP address**, enter the following values, and then choose **OK**.

Field	Value
IP address	The IPv4 address obtained in step 2 above.
Subnet mask	The subnet mask obtained in step 2 above.
Default gateway	The default gateway address obtained in step 2 above.
Preferred DNS server	The DNS server obtained in step 2 above.
Alternate DNS server	The alternate DNS server obtained in step 2 above. If an alternate DNS server was not listed, leave this field blank.

Important

If you set the IP address to any value other than the current IP address, you will lose connectivity to the instance.

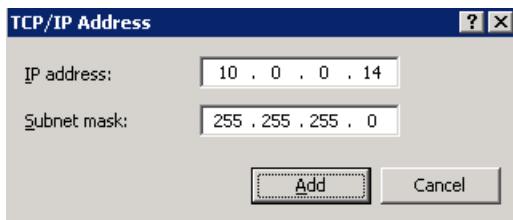

You will lose RDP connectivity to the Windows instance for a few seconds while the instance converts from using DHCP to static addressing. The instance retains the same IP address information as before, but now this information is static and not managed by DHCP.

Step 2: Configure a secondary private IP address for your instance

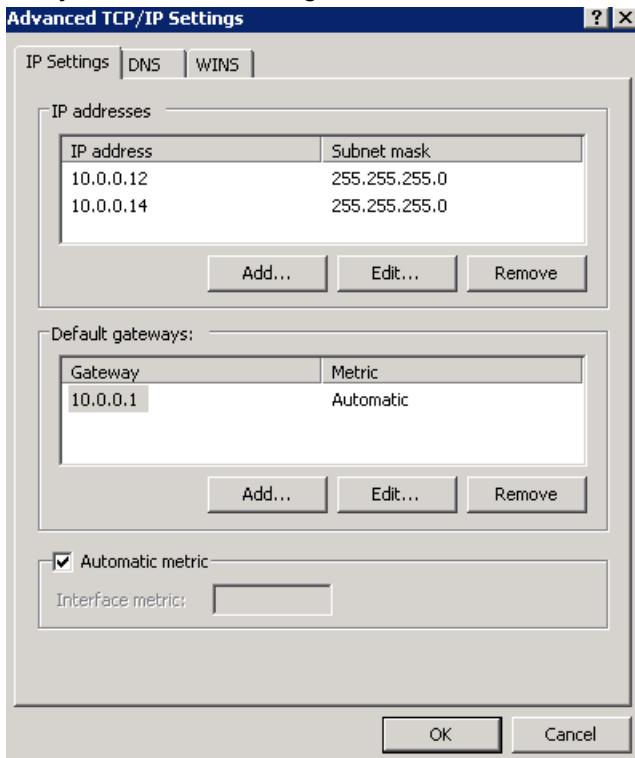

After you have set up static IP addressing on your Windows instance, you are ready to prepare a second private IP address.

To configure a secondary IP address

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances** and select your instance.
3. On the **Networking**, note the secondary IP address.
4. Connect to your instance.
5. On your Windows instance, choose **Start, Control Panel**.
6. Choose **Network and Internet, Network and Sharing Center**.
7. Select the network interface (Local Area Connection) and choose **Properties**.
8. On the **Local Area Connection Properties** page, choose **Internet Protocol Version 4 (TCP/IPv4), Properties, Advanced**.
9. Choose **Add**.
10. In the **TCP/IP Address** dialog box, type the secondary private IP address for **IP address**. For **Subnet mask**, type the same subnet mask that you entered for the primary private IP address in [Step 1: Configure static IP addressing on your instance \(p. 849\)](#), and then choose **Add**.

11. Verify the IP address settings and choose **OK**.

12. Choose **OK, Close**.
13. To confirm that the secondary IP address has been added to the operating system, at a command prompt, run the command **ipconfig /all**.

Step 3: Configure applications to Use the secondary private IP address

You can configure any applications to use the secondary private IP address. For example, if your instance is running a website on IIS, you can configure IIS to use the secondary private IP address.

To configure IIS to use the secondary private IP address

1. Connect to your instance.
2. Open Internet Information Services (IIS) Manager.
3. In the **Connections** pane, expand **Sites**.
4. Open the context (right-click) menu for your website and choose **Edit Bindings**.
5. In the **Site Bindings** dialog box, for **Type**, choose **http, Edit**.
6. In the **Edit Site Binding** dialog box, for **IP address**, select the secondary private IP address. (By default, each website accepts HTTP requests from all IP addresses.)

7. Choose **OK**, **Close**.

Run commands on your Windows instance at launch

When you launch a Windows instance using Amazon EC2, you can pass user data to the instance that can be used to perform automated configuration tasks, or to run scripts after the instance starts. Instance user data is treated as opaque data; it is up to the instance to interpret it. User data is processed by [EC2Launch v2 \(p. 692\)](#) on Windows Server 2022, [EC2Launch \(p. 743\)](#) on Windows Server 2016 and 2019, and [EC2Config \(p. 753\)](#) on Windows Server 2012 R2 and earlier.

For examples of the assembly of a `UserData` property in a AWS CloudFormation template, see [Base64 Encoded UserData Property](#) and [Base64 Encoded UserData Property with AccessKey and SecretKey](#).

For information about running commands on your Linux instance at launch, see [Running commands on your Linux instance at launch](#) in the *Amazon EC2 User Guide for Linux Instances*.

For an example of running commands on an instance within an Auto Scaling that work with lifecycle hooks, see [Tutorial: Configure user data to retrieve the target lifecycle state through instance metadata](#) in the *Amazon EC2 Auto Scaling User Guide*.

Contents

- [User data scripts \(p. 853\)](#)
- [User data execution \(p. 856\)](#)
- [User data and the console \(p. 858\)](#)
- [User data and the Tools for Windows PowerShell \(p. 860\)](#)

User data scripts

For EC2Config or EC2Launch to run scripts, you must enclose the script within a special tag when you add it to user data. The tag that you use depends on whether the commands run in a Command Prompt window (batch commands) or use Windows PowerShell.

If you specify both a batch script and a Windows PowerShell script, the batch script runs first and the Windows PowerShell script runs next, regardless of the order in which they appear in the instance user data.

If you use an AWS API, including the AWS CLI, in a user data script, you must use an instance profile when launching the instance. An instance profile provides the appropriate AWS credentials required by the user data script to make the API call. For more information, see [Instance profiles \(p. 1650\)](#). The permissions you assign to the IAM role depend on which services you are calling with the API. For more information, see [IAM roles for Amazon EC2](#).

Script type

- [Syntax for batch scripts \(p. 854\)](#)
- [Syntax for Windows PowerShell scripts \(p. 854\)](#)
- [Syntax for YAML configuration scripts \(p. 855\)](#)
- [Base64 encoding \(p. 856\)](#)

Syntax for batch scripts

Specify a batch script using the `<script>` tag. Separate the commands using line breaks as shown in the following example.

```
<script>
echo Current date and time >> %SystemRoot%\Temp\test.log
echo %DATE% %TIME% >> %SystemRoot%\Temp\test.log
</script>
```

By default, user data scripts run one time when you launch the instance. To run the user data scripts every time you reboot or start the instance, add `<persist>true</persist>` to the user data.

```
<script>
echo Current date and time >> %SystemRoot%\Temp\test.log
echo %DATE% %TIME% >> %SystemRoot%\Temp\test.log
</script>
<persist>true</persist>
```

EC2Launch v2 agent

To run an XML user data script as a detached process with the EC2Launch v2 **executeScript** task in the `Userdata` stage, add the following tag to your user data.

```
<detach>true</detach>
```

Note

The `detach` tag is not supported on previous launch agents.

```
<script>
echo Current date and time >> %SystemRoot%\Temp\test.log
echo %DATE% %TIME% >> %SystemRoot%\Temp\test.log
</script>
<detach>true</detach>
```

Syntax for Windows PowerShell scripts

The AWS Windows AMIs include the [AWS Tools for Windows PowerShell](#), so you can specify these cmdlets in user data. If you associate an IAM role with your instance, you don't need to specify credentials to the cmdlets, as applications that run on the instance use the role's credentials to access AWS resources (for example, Amazon S3 buckets).

Specify a Windows PowerShell script using the `<powershell>` tag. Separate the commands using line breaks. The `<powershell>` tag is case-sensitive.

For example:

```
<powershell>
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
```

```
</powershell>
```

By default, the user data scripts are run one time when you launch the instance. To run the user data scripts every time you reboot or start the instance, add `<persist>true</persist>` to the user data.

```
<powershell>
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

EC2Launch v2 agent

To run an XML user data script as a detached process with the EC2Launch v2 `executeScript` task in the `UserData` stage, add the following tag to your user data.

```
<detach>true</detach>
```

Note

The `detach` tag is not supported on previous launch agents.

```
<powershell>
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
<detach>true</detach>
```

Syntax for YAML configuration scripts

If you are using EC2Launch v2 to run scripts, you can use the YAML format. To view configuration tasks, details, and examples for EC2Launch v2, see [EC2Launch v2 task configuration \(p. 716\)](#).

Specify a YAML script with the `executeScript` task.

Example YAML syntax to run a PowerShell script

```
version: 1.0
tasks:
- task: executeScript
  inputs:
    - frequency: always
      type: powershell
      runAs: localSystem
  content: |-
    $file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
    New-Item $file -ItemType file
```

Example YAML syntax to run a batch script

```
version: 1.1
tasks:
- task: executeScript
  inputs:
    - frequency: always
      type: batch
      runAs: localSystem
  content: |-
    echo Current date and time >> %SystemRoot%\Temp\test.log
    echo %DATE% %TIME% >> %SystemRoot%\Temp\test.log
```

Base64 encoding

If you're using the Amazon EC2 API or a tool that does not perform base64 encoding of the user data, you must encode the user data yourself. If not, an error is logged about being unable to find script or powershell tags to run. The following is an example that encodes using Windows PowerShell.

```
$UserData =  
[System.Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($Script))
```

The following is an example that decodes using PowerShell.

```
$Script =  
[System.Text.Encoding]::UTF8.GetString([System.Convert]::FromBase64String($UserData))
```

For more information about base64 encoding, see <https://www.ietf.org/rfc/rfc4648.txt>.

User data execution

By default, all AWS Windows AMIs have user data execution enabled for the initial launch. You can specify that user data scripts are run the next time the instance reboots or restarts. Alternatively, you can specify that user data scripts are run every time the instance reboots or restarts.

Note

User data is not enabled to run by default after the initial launch. To enable user data to run when you reboot or start the instance, see [Subsequent reboots or starts \(p. 857\)](#).

User data scripts are run from the local administrator account when a random password is generated. Otherwise, user data scripts are run from the System account.

Instance launch

Scripts in the instance user data are run during the initial launch of the instance. If the `persist` tag is found, user data execution is enabled for subsequent reboots or starts. The log files for EC2Launch v2, EC2Launch, and EC2Config contain the output from the standard output and standard error streams.

EC2Launch v2

The log file for EC2Launch v2 is `C:\ProgramData\Amazon\EC2Launch\log\agent.log`.

Note

The `C:\ProgramData` folder might be hidden. To view the folder, you must show hidden files and folders.

The following information is logged when the user data is run:

- Info: Converting user-data to yaml format – If the user data was provided in XML format
- Info: Initializing user-data state – The start of user data execution
- Info: Frequency is: always – If the user data task is running on every boot
- Info: Frequency is: once – If the user data task is running just once
- Stage: postReadyUserData execution completed – The end of user data execution

EC2Launch

The log file for EC2Launch is `C:\ProgramData\Amazon\EC2-Windows\Launch\Log\UserdataExecution.log`.

The `C:\ProgramData` folder might be hidden. To view the folder, you must show hidden files and folders.

The following information is logged when the user data is run:

- Userdata execution begins – The start of user data execution
- <persist> tag was provided: true – If the persist tag is found
- Running userdata on every boot – If the persist tag is found
- <powershell> tag was provided.. running powershell content – If the powershell tag is found
- <script> tag was provided.. running script content – If the script tag is found
- Message: The output from user scripts – If user data scripts are run, their output is logged

EC2Config

The log file for EC2Config is C:\Program Files\Amazon\Ec2ConfigService\Logs\Ec2Config.log. The following information is logged when the user data is run:

- Ec2HandleUserData: Message: Start running user scripts – The start of user data execution
- Ec2HandleUserData: Message: Re-enabled userdata execution – If the persist tag is found
- Ec2HandleUserData: Message: Could not find <persist> and </persist> – If the persist tag is not found
- Ec2HandleUserData: Message: The output from user scripts – If user data scripts are run, their output is logged

Subsequent reboots or starts

When you update instance user data, user data scripts are not run automatically when you reboot or start the instance. However, you can enable user data execution so that user data scripts are run one time when you reboot or start the instance, or every time you reboot or start the instance.

If you choose the **Shutdown with Sysprep** option, user data scripts are run the next time the instance starts or reboots, even if you did not enable user data execution for subsequent reboots or starts. The user data scripts will not be executed on subsequent reboots or starts.

To enable user data execution with EC2Launch v2 (Preview AMIs)

- To run a task in user data on first boot, set frequency to once.
- To run a task in user data on every boot, set frequency to always.

To enable user data execution with EC2Launch (Windows Server 2016 or later)

1. Connect to your Windows instance.
2. Open a PowerShell command window and run the following command:

```
C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -Schedule
```

3. Disconnect from your Windows instance. To run updated scripts the next time the instance is started, stop the instance and update the user data. For more information, see [View and update the instance user data \(p. 859\)](#).

To enable user data execution with EC2Config (Windows Server 2012 R2 and earlier)

1. Connect to your Windows instance.

2. Open C:\Program Files\Amazon\Ec2ConfigService\Ec2ConfigServiceSetting.exe.
3. For **User Data**, select **Enable UserData execution for next service start**.
4. Disconnect from your Windows instance. To run updated scripts the next time the instance is started, stop the instance and update the user data. For more information, see [View and update the instance user data \(p. 859\)](#).

User data and the console

You can specify instance user data when you launch the instance. If the root volume of the instance is an EBS volume, you can also stop the instance and update its user data.

Specify instance user data at launch

Follow the procedure for [launching an instance \(p. 554\)](#). The **User data** field is located in the [Advanced details \(p. 559\)](#) section of the launch instance wizard. Enter your PowerShell script in the **User data** field, and then complete the instance launch procedure.

In the following screenshot of the **User data** field, the example script creates a file in the Windows temporary folder, using the current date and time in the file name. When you include <persist>true</persist>, the script is run every time you reboot or start the instance. If you leave the **User data has already been base64 encoded** check box empty, the Amazon EC2 console performs the base64 encoding for you.

User data - optional [Info](#)

Enter user data in the field.

```
<powershell>
$file = $env:SystemRoot+"\Temp\"+(Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

User data has already been base64 encoded

View and update the instance user data

You can view the instance user data for any instance, and you can update the instance user data for a stopped instance.

To update the user data for an instance using the console

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Instance state, Stop instance**.

Warning

When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

4. When prompted for confirmation, choose **Stop**. It can take a few minutes for the instance to stop.
5. With the instance still selected, choose **Actions, Instance settings, Edit user data**. You can't change the user data if the instance is running, but you can view it.
6. In the **Edit user data** dialog box, update the user data, and then choose **Save**. To run user data scripts every time you reboot or start the instance, add `<persist>true</persist>`, as shown in the following example:

Edit user data Info

Instance ID
 [I-0655799f982552ec9](#)

Current user data
User data currently associated with this instance

```
<powershell>
$file = $env:SystemRoot+"\Temp\"+(Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
```

New user data
This user data will replace the current user data

Modify user data as text
Add your user data below

Modify user data by importing a file
Description of importing a file and what will happen to it

```
<powershell>
$file = $env:SystemRoot+"\Temp\"+(Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

Input is already base64-encoded

7. Start the instance. If you enabled user data execution for subsequent reboots or starts, the updated user data scripts are run as part of the instance start process.

User data and the Tools for Windows PowerShell

You can use the Tools for Windows PowerShell to specify, modify, and view the user data for your instance. For information about viewing user data from your instance using instance metadata, see [Retrieve instance user data \(p. 885\)](#). For information about user data and the AWS CLI, see [User data and the AWS CLI](#) in the *Amazon EC2 User Guide for Linux Instances*.

Example: Specify instance user data at launch

Create a text file with the instance user data. To run user data scripts every time you reboot or start the instance, add `<persist>true</persist>`, as shown in the following example.

```
<powershell>
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
```

```
</powershell>
<persist>true</persist>
```

To specify instance user data when you launch your instance, use the [New-EC2Instance](#) command. This command does not perform base64 encoding of the user data for you. Use the following commands to encode the user data in a text file named script.txt.

```
PS C:\> $Script = Get-Content -Raw script.txt
PS C:\> $UserData =
[System.Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($Script))
```

Use the -UserData parameter to pass the user data to the [New-EC2Instance](#) command.

```
PS C:\> New-EC2Instance -ImageId ami-abcd1234 -MinCount 1 -MaxCount 1 -
InstanceType m3.medium \
-KeyName my-key-pair -SubnetId subnet-12345678 -SecurityGroupIds sg-1a2b3c4d \
-UserData $UserData
```

Example: Update instance user data for a stopped instance

You can modify the user data of a stopped instance using the [Edit-EC2InstanceAttribute](#) command.

Create a text file with the new script. Use the following commands to encode the user data in the text file named new-script.txt.

```
PS C:\> $NewScript = Get-Content -Raw new-script.txt
PS C:\> $NewUserData =
[System.Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($NewScript))
```

Use the -UserData and -Value parameters to specify the user data.

```
PS C:\> Edit-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -Attribute userData -
Value $NewUserData
```

Example: View instance user data

To retrieve the user data for an instance, use the [Get-EC2InstanceAttribute](#) command.

```
PS C:\> (Get-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -Attribute
userData).UserData
```

The following is example output. Note that the user data is encoded.

```
PHBvd2Vyc2h1bGw
+DQpSZW5hbWUtQ29tcHV0ZXIgLU51d05hbWUgdXNlcj1kYXRhLXRlc3QNCjwvcG93ZXJzaGVsbD4=
```

Use the following commands to store the encoded user data in a variable and then decode it.

```
PS C:\> $UserData_encoded = (Get-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -
Attribute userData).UserData
PS C:
\> [System.Text.Encoding]::UTF8.GetString([System.Convert]::FromBase64String($UserData_encoded))
```

The following is example output.

```
<powershell>
```

```
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

Example: Rename the instance to match the tag value

You can use the [Get-EC2Tag](#) command to read the tag value, rename the instance on first boot to match the tag value, and reboot. To run this command successfully, you must have a role with ec2:DescribeTags permissions attached to the instance because tag information is retrieved by the API call. For more information on settings permissions by using IAM roles, see [Attaching an IAM Role to an Instance](#).

Note

This script fails on Windows Server versions prior to 2008.

```
<powershell>
$instanceId = (invoke-webrequest http://169.254.169.254/latest/meta-data/instance-id - 
UseBasicParsing).content
$nameValue = (get-ec2tag -filter @{Name="resource-id";Value=
$instanceid},@{Name="key";Value="Name"}).Value
$pattern = "^(?!|[0-9]{1,15})[a-zA-Z0-9-]{1,15}$"
#Verify Name Value satisfies best practices for Windows hostnames
If ($nameValue -match $pattern)
{
    Try
        {Rename-Computer -NewName $nameValue -Restart -ErrorAction Stop}
    Catch
        {$ErrorMessage = $_.Exception.Message
        Write-Output "Rename failed: $ErrorMessage"}
}
Else
{
    Throw "Provided name not a valid hostname. Please ensure Name value is between 1 and
15 characters in length and contains only alphanumeric or hyphen characters"
</powershell>
```

You can also rename the instance using tags in instance metadata, if your instance is configured to [access tags from the instance metadata](#).

Note

This script fails on Windows Server versions prior to 2008.

```
<powershell>
$nameValue = Get-EC2InstanceMetadata -Path /tags/instance/Name
$pattern = "^(?!|[0-9]{1,15})[a-zA-Z0-9-]{1,15}$"
#Verify Name Value satisfies best practices for Windows hostnames
If ($nameValue -match $pattern)
{
    Try
        {Rename-Computer -NewName $nameValue -Restart -ErrorAction Stop}
    Catch
        {$ErrorMessage = $_.Exception.Message
        Write-Output "Rename failed: $ErrorMessage"}
}
Else
{
    Throw "Provided name not a valid hostname. Please ensure Name value is between 1 and
15 characters in length and contains only alphanumeric or hyphen characters"
</powershell>
```

Instance metadata and user data

Instance metadata is data about your instance that you can use to configure or manage the running instance. Instance metadata is divided into [categories \(p. 887\)](#), for example, host name, events, and security groups.

You can also use instance metadata to access *user data* that you specified when launching your instance. For example, you can specify parameters for configuring your instance, or include a simple script. You can build generic AMIs and use user data to modify the configuration files supplied at launch time. For example, if you run web servers for various small businesses, they can all use the same generic AMI and retrieve their content from the Amazon S3 bucket that you specify in the user data at launch. To add a new customer at any time, create a bucket for the customer, add their content, and launch your AMI with the unique bucket name provided to your code in the user data. If you launch more than one instance at the same time, the user data is available to all instances in that reservation. Each instance that is part of the same reservation has a unique ami-launch-index number, allowing you to write code that controls what to do. For example, the first host might elect itself as the original node in a cluster.

EC2 instances can also include *dynamic data*, such as an instance identity document that is generated when the instance is launched. For more information, see [Dynamic data categories \(p. 896\)](#).

Important

Although you can only access instance metadata and user data from within the instance itself, the data is not protected by authentication or cryptographic methods. Anyone who has direct access to the instance, and potentially any software running on the instance, can view its metadata. Therefore, you should not store sensitive data, such as passwords or long-lived encryption keys, as user data.

Note

The examples in this topic use the IPv4 address of the Instance Metadata Service (IMDS): 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 218\)](#).

Contents

- [Use IMDSv2 \(p. 863\)](#)
- [Configure the instance metadata options \(p. 868\)](#)
- [Retrieve instance metadata \(p. 876\)](#)
- [Work with instance user data \(p. 885\)](#)
- [Retrieve dynamic data \(p. 886\)](#)
- [Instance metadata categories \(p. 887\)](#)
- [Instance identity documents \(p. 896\)](#)
- [Instance identity roles \(p. 925\)](#)

Use IMDSv2

You can access instance metadata from a running instance using one of the following methods:

- Instance Metadata Service Version 1 (IMDSv1) – a request/response method
- Instance Metadata Service Version 2 (IMDSv2) – a session-oriented method

By default, you can use either IMDSv1 or IMDSv2, or both. The instance metadata service distinguishes between IMDSv1 and IMDSv2 requests based on whether, for any given request, either the PUT or GET headers, which are unique to IMDSv2, are present in that request.

You can configure the Instance Metadata Service (IMDS) on each instance so that local code or users must use IMDSv2. When you specify that IMDSv2 must be used, IMDSv1 no longer works. For information about how to configure your instance to use IMDSv2, see [Configure the instance metadata options \(p. 868\)](#).

For an extensive review of IMDSv2, see [Add defense in depth against open firewalls, reverse proxies, and SSRF vulnerabilities with enhancements to the EC2 Instance Metadata Service](#).

To retrieve instance metadata, see [Retrieve instance metadata \(p. 876\)](#).

Topics

- [How Instance Metadata Service Version 2 works \(p. 864\)](#)
- [Transition to using Instance Metadata Service Version 2 \(p. 865\)](#)
- [Use a supported AWS SDK \(p. 868\)](#)

How Instance Metadata Service Version 2 works

IMDSv2 uses session-oriented requests. With session-oriented requests, you create a session token that defines the session duration, which can be a minimum of one second and a maximum of six hours. During the specified duration, you can use the same session token for subsequent requests. After the specified duration expires, you must create a new session token to use for future requests.

Note

The examples in this section use the IPv4 address of the Instance Metadata Service (IMDS): 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 218\)](#).

The following example uses a PowerShell shell script and IMDSv2 to retrieve the top-level instance metadata items. The example:

- Creates a session token lasting six hours (21,600 seconds) using the PUT request
- Stores the session token header in a variable named token
- Requests the top-level metadata items using the token

```
PS C:\> [string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
PS C:\> Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} -Method GET -Uri http://169.254.169.254/latest/meta-data/
```

After you've created a token, you can reuse it until it expires. In the following example command, which gets the ID of the AMI used to launch the instance, the token that is stored in \$token in the previous example is reused.

```
PS C:\> Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} ` -Method GET -uri http://169.254.169.254/latest/meta-data/ami-id
```

When you use IMDSv2 to request instance metadata, the request must include the following:

1. Use a PUT request to initiate a session to the instance metadata service. The PUT request returns a token that must be included in subsequent GET requests to the instance metadata service. The token is required to access metadata using IMDSv2.
2. Include the token in all GET requests to the IMDS. When token usage is set to required, requests without a valid token or with an expired token receive a 401 – Unauthorized HTTP error code.
 - The token is an instance-specific key. The token is not valid on other EC2 instances and will be rejected if you attempt to use it outside of the instance on which it was generated.

- The PUT request must include a header that specifies the time to live (TTL) for the token, in seconds, up to a maximum of six hours (21,600 seconds). The token represents a logical session. The TTL specifies the length of time that the token is valid and, therefore, the duration of the session.
- After a token expires, to continue accessing instance metadata, you must create a new session using another PUT.
- You can choose to reuse a token or create a new token with every request. For a small number of requests, it might be easier to generate and immediately use a token each time you need to access the IMDS. But for efficiency, you can specify a longer duration for the token and reuse it rather than having to write a PUT request every time you need to request instance metadata. There is no practical limit on the number of concurrent tokens, each representing its own session. IMDSv2 is, however, still constrained by normal IMDS connection and throttling limits. For more information, see [Query throttling \(p. 883\)](#).

HTTP GET and HEAD methods are allowed in IMDSv2 instance metadata requests. PUT requests are rejected if they contain an X-Forwarded-For header.

By default, the response to PUT requests has a response hop limit (time to live) of 1 at the IP protocol level. If you need a bigger hop limit, you can adjust it by using the [modify-instance-metadata-options](#) AWS CLI command. For example, you might need a bigger hop limit for backward compatibility with container services running on the instance. For more information, see [Modify instance metadata options for existing instances \(p. 872\)](#).

Transition to using Instance Metadata Service Version 2

When migrating to IMDSv2, we recommend that you use the following tools and transition path.

Topics

- [Tools for helping with the transition to IMDSv2 \(p. 865\)](#)
- [Recommended path to requiring IMDSv2 \(p. 867\)](#)

Tools for helping with the transition to IMDSv2

If your software uses IMDSv1, use the following tools to help reconfigure your software to use IMDSv2.

AWS software

The latest versions of the AWS CLI and AWS SDKs support IMDSv2. To use IMDSv2, make sure that your EC2 instances have the latest versions of the CLI and SDKs. For information about updating the CLI, see [Installing, updating, and uninstalling the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

All Amazon Linux 2 software packages support IMDSv2.

For the minimum AWS SDK versions that support IMDSv2, see [Use a supported AWS SDK \(p. 868\)](#).

IMDS Packet Analyzer

The IMDS Packet Analyzer is an open-sourced tool that identifies and logs IMDSv1 calls from your instance's boot phase. This can assist in identifying the software making IMDSv1 calls on EC2 instances, allowing you to pinpoint exactly what you need to update to get your instances ready to use IMDSv2 only. You can run IMDS Packet Analyzer from a command line or install it as a service. For more information, see [IMDS Packet Analyzer on GitHub](#).

CloudWatch

IMDSv2 uses token-backed sessions, while IMDSv1 does not. The `MetadataNoToken` CloudWatch metric tracks the number of calls to the Instance Metadata Service (IMDS) that are using IMDSv1. By

tracking this metric to zero, you can determine if and when all of your software has been upgraded to use IMDSv2. For more information, see [Instance metrics \(p. 1185\)](#).

Updates to EC2 APIs and CLIs

For new instances, you can use the [RunInstances](#) API to launch new instances that require the use of IMDSv2. For more information, see [Configure instance metadata options for new instances \(p. 869\)](#).

For existing instances, you can use the [ModifyInstanceMetadataOptions](#) API to require the use of IMDSv2. For more information, see [Modify instance metadata options for existing instances \(p. 872\)](#).

To require the use of IMDSv2 on all new instances launched by Auto Scaling groups, your Auto Scaling groups can use either a launch template or a launch configuration. When you [create a launch template](#) or [create a launch configuration](#), you must configure the `MetadataOptions` parameters to require the use of IMDSv2. The Auto Scaling group launches new instances using the new launch template or launch configuration, but existing instances are not affected. For existing instances in an Auto Scaling group, you can use the [ModifyInstanceMetadataOptions](#) API to require the use of IMDSv2 on the existing instances, or terminate the instances and the Auto Scaling group will launch new replacement instances with the instance metadata options settings that are defined in the new launch template or launch configuration.

Use an AMI that configures IMDSv2 by default

When you launch an instance, you can automatically configure it to use IMDSv2 by default (the `HttpTokens` parameter is set to `required`) by launching it with an AMI that is configured with the `ImdsSupport` parameter set to `v2.0`. You can set the `ImdsSupport` parameter to `v2.0` when you register the AMI using the [register-image](#) CLI command, or you can modify an existing AMI by using the [modify-image-attribute](#) CLI command. For more information, see [Configure the AMI \(p. 870\)](#).

IAM policies and SCPs

You can use an IAM policy or AWS Organizations service control policy (SCP) to control users as follows:

- Can't launch an instance using the [RunInstances](#) API unless the instance is configured to use IMDSv2.
- Can't modify a running instance using the [ModifyInstanceMetadataOptions](#) API to re-enable IMDSv1.

The IAM policy or SCP must contain the following IAM condition keys:

- `ec2:MetadataHttpEndpoint`
- `ec2:MetadataHttpPutResponseHopLimit`
- `ec2:MetadataHttpTokens`

If a parameter in the API or CLI call does not match the state specified in the policy that contains the condition key, the API or CLI call fails with an `UnauthorizedOperation` response.

Furthermore, you can choose an additional layer of protection to enforce the change from IMDSv1 to IMDSv2. At the access management layer with respect to the APIs called via EC2 Role credentials, you can use a new condition key in either IAM policies or AWS Organizations service control policies (SCPs). Specifically, by using the condition key `ec2:RoleDelivery` with a value of `2.0` in your IAM policies, API calls made with EC2 Role credentials obtained from IMDSv1 will receive an `UnauthorizedOperation` response. The same thing can be achieved more broadly with that condition required by an SCP. This ensures that credentials delivered via IMDSv1 cannot actually be used to call APIs because any API calls not matching the specified condition will receive an `UnauthorizedOperation` error.

For example IAM policies, see [Work with instance metadata \(p. 1635\)](#). For more information on SCPs, see [Service Control Policies](#) in the *AWS Organizations User Guide*.

Recommended path to requiring IMDSv2

Using the above tools, we recommend that you follow this path for transitioning to IMDSv2.

Step 1: At the start

Update the SDKs, CLIs, and your software that use Role credentials on their EC2 instances to versions compatible with IMDSv2. For information about updating the CLI, see [Upgrading to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

Then, change your software that directly accesses instance metadata (in other words, that does not use an SDK) using the IMDSv2 requests. You can use the [IMDS Packet Analyzer](#) to identify the software that you need to change to use IMDSv2 requests.

Step 2: Track your transition progress

Track your transition progress by using the CloudWatch metric `MetadataNoToken`. This metric shows the number of IMDSv1 calls to the IMDS on your instances. For more information, see [Instance metrics \(p. 1185\)](#).

Step 3: When there is zero IMDSv1 usage

When the CloudWatch metric `MetadataNoToken` records zero IMDSv1 usage, your instances are ready to be fully transitioned to using IMDSv2. At this stage, you can do the following:

- **New instances**

When launching a new instance, you can do the following:

- Amazon EC2 console: In the launch instance wizard, set **Metadata accessible** to **Enabled** and **Metadata version** to **V2 only (token required)**. For more information, see [Configure the instance at launch \(p. 869\)](#).
- AWS CLI: Use the [run-instances](#) CLI command to specify that only IMDSv2 is to be used.

- **Existing instances**

For existing instances, you can do the following:

- Amazon EC2 console: On the **Instances** page, select your instance, choose **Actions, Instance settings, Modify instance metadata options**, and for **IMDSv2**, choose **Required**. For more information, see [Require the use of IMDSv2 \(p. 873\)](#).
- AWS CLI: Use the [modify-instance-metadata-options](#) CLI command to specify that only IMDSv2 is to be used.

You can modify the instance metadata options on running instances, and you don't need to restart the instances after modifying the instance metadata options.

Step 4: Check if your instances are transitioned to IMDSv2

You can check if any instances are not yet configured to require the use of IMDSv2, in other words, IMDSv2 is still configured as optional. If any instances are still configured as optional, you can modify the instance metadata options to make IMDSv2 required by repeating the preceding [Step 3 \(p. 867\)](#).

To filter your instances:

- Amazon EC2 console: On the **Instances** page, filter your instances by using the **IMDSv2 = optional** filter. For more information about filtering, see [Filter resources using the console \(p. 2077\)](#). You can also view whether IMDSv2 is required or optional for each instance: In the **Preferences** window, toggle on **IMDSv2** to add the **IMDSv2** column to the **Instances** table.

- AWS CLI: Use the [describe-instances](#) CLI command and filter by `metadata-options.http-tokens = optional`, as follows:

```
aws ec2 describe-instances --filters "Name=metadata-options.http-tokens,Values=optional"
--query "Reservations[*].Instances[*].[InstanceId]" --output text
```

Step 5: When all of your instances are transitioned to IMDSv2

The `ec2:MetadataHttpTokens`, `ec2:MetadataHttpPutResponseHopLimit`, and `ec2:MetadataHttpEndpoint` IAM condition keys can be used to control the use of the [RunInstances](#) and the [ModifyInstanceMetadataOptions](#) APIs and corresponding CLIs. If a policy is created, and a parameter in the API call does not match the state specified in the policy using the condition key, the API or CLI call fails with an `UnauthorizedOperation` response. For example IAM policies, see [Work with instance metadata \(p. 1635\)](#).

Use a supported AWS SDK

To use IMDSv2, your EC2 instances must use an AWS SDK version that supports using IMDSv2. The latest versions of the all AWS SDKs support using IMDSv2.

Important

We recommend that you stay up to date with SDK releases to keep up with the latest features, security updates, and underlying dependencies. Continued use of an unsupported SDK version is not recommended and is done at your discretion. For more information, see the [AWS SDKs and Tools maintenance policy](#) in the *AWS SDKs and Tools Reference Guide*.

The following are the minimum versions that support using IMDSv2:

- [AWS CLI](#) – 1.16.289
- [AWS Tools for Windows PowerShell](#) – 4.0.1.0
- [AWS SDK for .NET](#) – 3.3.634.1
- [AWS SDK for C++](#) – 1.7.229
- [AWS SDK for Go](#) – 1.25.38
- [AWS SDK for Go v2](#) – 0.19.0
- [AWS SDK for Java](#) – 1.11.678
- [AWS SDK for Java 2.x](#) – 2.10.21
- [AWS SDK for JavaScript in Node.js](#) – 2.722.0
- [AWS SDK for PHP](#) – 3.147.7
- [AWS SDK for Python \(Boto\)](#) – 1.13.25
- [AWS SDK for Python \(Boto3\)](#) – 1.12.6
- [AWS SDK for Ruby](#) – 3.79.0

Configure the instance metadata options

Instance metadata options allow you to configure new or existing instances to do the following:

- Require the use of IMDSv2 when requesting instance metadata
- Specify the PUT response hop limit
- Turn off access to instance metadata

You can also use IAM condition keys in an IAM policy or SCP to do the following:

- Allow an instance to launch only if it's configured to require the use of IMDSv2
- Restrict the number of allowed hops
- Turn off access to instance metadata

Note

If your PowerShell version is earlier than 4.0, you must [update to Windows Management Framework 4.0](#) to require the use of IMDSv2.

Note

You should proceed cautiously and conduct careful testing before making any changes. Take note of the following:

- If you enforce the use of IMDSv2, applications or agents that use IMDSv1 for instance metadata access will break.
- If you turn off all access to instance metadata, applications or agents that rely on instance metadata access to function will break.
- For IMDSv2, you must use /latest/api/token when retrieving the token.

Topics

- [Configure instance metadata options for new instances \(p. 869\)](#)
- [Modify instance metadata options for existing instances \(p. 872\)](#)

Configure instance metadata options for new instances

Topics

- [Require the use of IMDSv2 \(p. 869\)](#)
- [Configure IPv4 and IPv6 endpoints \(p. 871\)](#)
- [Turn off access to instance metadata \(p. 871\)](#)

Require the use of IMDSv2

There are various ways that you can require that IMDSv2 is used on an instance at launch, as follows:

- [Configure the instance at launch \(p. 869\)](#)
- [Configure the AMI \(p. 870\)](#)
- [Use an IAM policy \(p. 871\)](#)

Configure the instance at launch

When you [launch an instance \(p. 554\)](#), you can configure the instance to require the use of IMDSv2 by configuring the following fields:

- Amazon EC2 console: Set **Metadata version** to **V2 only (token required)**.
- AWS CLI: Set `HttpTokens` to `required`.

When you specify that IMDSv2 is required, you must also enable the Instance Metadata Service (IMDS) endpoint by setting **Metadata accessible** to **Enabled** (console) or `HttpEndpoint` to `enabled` (AWS CLI).

New console

To require the use of IMDSv2 on a new instance

- When launching a new instance in the Amazon EC2 console, expand **Advanced details**, and do the following:
 - For **Metadata accessible**, choose **Enabled**.
 - For **Metadata version**, choose **V2 only (token required)**.

For more information, see [Advanced details \(p. 559\)](#).

Old console

To require the use of IMDSv2 on a new instance

- When launching a new instance in the Amazon EC2 console, select the following options on the **Configure Instance Details** page:
 - Under **Advanced Details**, for **Metadata accessible**, select **Enabled**.
 - For **Metadata version**, select **V2 (token required)**.

For more information, see [Step 3: Configure Instance Details \(p. 563\)](#).

AWS CLI

To require the use of IMDSv2 on a new instance

The following `run-instances` example launches a `c3.large` instance with `--metadata-options` set to `HttpTokens=required`. When you specify a value for `HttpTokens`, you must also set `HttpEndpoint` to `enabled`. Because the secure token header is set to `required` for metadata retrieval requests, this requires the instance to use IMDSv2 when requesting instance metadata.

```
aws ec2 run-instances \
  --image-id ami-0abcdef1234567890 \
  --instance-type c3.large \
  ...
  --metadata-options "HttpEndpoint=enabled,HttpTokens=required"
```

AWS CloudFormation

To specify the metadata options for an instance using AWS CloudFormation, see the [AWS::EC2::LaunchTemplate MetadataOptions](#) property in the [AWS CloudFormation User Guide](#).

Configure the AMI

When you register a new AMI or modify an existing AMI, you can set the `imds-support` parameter to `v2.0`. Instances launched from this AMI will have **Metadata version** set to **V2 only (token required)** (console) or `HttpTokens` set to `required` (AWS CLI). With these settings, the instance requires that IMDSv2 is used when requesting instance metadata.

Note that when you set `imds-support` to `v2.0`, instances launched from this AMI will also have **Metadata response hop limit** (console) or `http-put-response-hop-limit` (AWS CLI) set to **2**.

Important

Do not use this parameter unless your AMI software supports IMDSv2. After you set the value to `v2.0`, you can't undo it. The only way to "reset" your AMI is to create a new AMI from the underlying snapshot.

To configure a new AMI for IMDSv2

The following [register-image](#) example registers an AMI using the specified snapshot of an EBS root volume as device /dev/xvda. Specify v2.0 for the imds-support parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```
aws ec2 register-image \
--name my-image \
--root-device-name /dev/xvda \
--block-device-mappings DeviceName=/dev/xvda,Ebs={SnapshotId=snap-0123456789example} \
--imds-support v2.0
```

To configure an existing AMI for IMDSv2

The following [modify-image-attribute](#) example modifies an existing AMI for IMDSv2 only. Specify v2.0 for the imds-support parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```
aws ec2 modify-image-attribute \
--image-id ami-0123456789example \
--imds-support v2.0
```

Use an IAM policy

You can create an IAM policy that prevents users from launching new instances unless they require IMDSv2 on the new instance.

To enforce the use of IMDSv2 on all new instances by using an IAM policy

To ensure that users can only launch instances that require the use of IMDSv2 when requesting instance metadata, you can specify that the condition to require IMDSv2 must be met before an instance can be launched. For the example IAM policy, see [Work with instance metadata \(p. 1635\)](#).

Configure IPv4 and IPv6 endpoints

By default, the IPv6 endpoint is disabled. This is true even if you are launching an instance into an IPv6-only subnet. You can choose to enable the IPv6 endpoint at instance launch when using the AWS CLI. This option is not available in the Amazon EC2 console.

The IPv6 endpoint for the IMDS is only accessible on [Instances built on the Nitro System \(p. 218\)](#).

Configure IPv4 and IPv6 endpoints

The following [run-instances](#) example launches a t3.large instance with the IPv6 endpoint enabled for the IMDS. To enable the IPv6 endpoint, for the --metadata-options parameter, specify HttpProtocolIpv6=enabled. When you specify a value for HttpProtocolIpv6, you must also set HttpEndpoint to enabled.

```
aws ec2 run-instances \
--image-id ami-0abcdef1234567890 \
--instance-type t3.large \
...
--metadata-options "HttpEndpoint=enabled,HttpProtocolIpv6=enabled"
```

Turn off access to instance metadata

You can ensure that access to your instance metadata is turned off, regardless of which version of the IMDS you are using. You can turn on access later. For more information, see [Turn on access to instance metadata \(p. 874\)](#).

New console

To turn off access to instance metadata

- [Launch the instance \(p. 554\)](#) in the Amazon EC2 console with the following specified under **Advanced details**:
 - For **Metadata accessible**, choose **Disabled**.

For more information, see [Advanced details \(p. 559\)](#).

Old console

To turn off access to instance metadata

- Launch the instance in the Amazon EC2 console with the following option selected on the **Configure Instance Details** page:
 - Under **Advanced Details**, for **Metadata accessible**, select **Disabled**.

For more information, see [Step 3: Configure Instance Details \(p. 563\)](#).

AWS CLI

To turn off access to instance metadata

Launch the instance with `--metadata-options` set to `HttpEndpoint=disabled`.

```
aws ec2 run-instances \  
  --image-id ami-0abcdef1234567890 \  
  --instance-type c3.large \  
  ... \  
  --metadata-options "HttpEndpoint=disabled"
```

AWS CloudFormation

To specify the metadata options for an instance using AWS CloudFormation, see the [AWS::EC2::LaunchTemplate MetadataOptions](#) property in the *AWS CloudFormation User Guide*.

Modify instance metadata options for existing instances

You can modify the instance metadata options for existing instances.

You can also create an IAM policy that prevents users from modifying the instance metadata options on existing instances. To control which users can modify the instance metadata options, specify a policy that prevents all users other than users with a specified role to use the [ModifyInstanceMetadataOptions](#) API. For the example IAM policy, see [Work with instance metadata \(p. 1635\)](#).

You can modify the following metadata options for existing instances:

- [Require the use of IMDSv2 \(p. 873\)](#)
- [Restore the use of IMDSv1 \(p. 873\)](#)
- [Change the PUT response hop limit \(p. 874\)](#)
- [Enable the IPv6 endpoint for your instance \(p. 874\)](#)
- [Turn on access to instance metadata \(p. 874\)](#)
- [Turn off access to instance metadata \(p. 875\)](#)

Require the use of IMDSv2

Use one of the following methods to modify the instance metadata options on an existing instance to require that IMDSv2 is used when requesting instance metadata. When IMDSv2 is required, IMDSv1 cannot be used.

Console

To require the use of IMDSv2 on an existing instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions, Instance settings, Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:
 - a. For **Instance metadata service**, select **Enable**.
 - b. For **IMDSv2**, choose **Required**.
 - c. Choose **Save**.

AWS CLI

To require the use of IMDSv2 on an existing instance

Use the [modify-instance-metadata-options](#) CLI command and set the `http-tokens` parameter to `required`. When you specify a value for `http-tokens`, you must also set `http-endpoint` to `enabled`.

```
aws ec2 modify-instance-metadata-options \
    --instance-id i-123456789abcdef0 \
    --http-tokens required \
    --http-endpoint enabled
```

Restore the use of IMDSv1

When IMDSv2 is required, IMDSv1 will not work when requesting instance metadata. When IMDSv2 is optional, then both IMDSv2 and IMDSv1 will work. Therefore, to restore IMDSv1, make IMDSv2 optional by using one of the following methods.

Console

To restore the use of IMDSv1 on an instance

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions, Instance settings, Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:
 - a. For **Instance metadata service**, make sure that **Enable** is selected.
 - b. For **IMDSv2**, choose **Optional**.
 - c. Choose **Save**.

AWS CLI

To restore the use of IMDSv1 on an instance

You can use the [modify-instance-metadata-options](#) CLI command with http-tokens set to optional to restore the use of IMDSv1 when requesting instance metadata.

```
aws ec2 modify-instance-metadata-options \
--instance-id i-1234567898abcdef0 \
--http-tokens optional \
--http-endpoint enabled
```

Change the PUT response hop limit

For existing instances, you can change the settings of the PUT response hop limit.

Currently only the AWS CLI and AWS SDKs support changing the PUT response hop limit.

To change the PUT response hop limit

Use the [modify-instance-metadata-options](#) CLI command and set the http-put-response-hop-limit parameter to the required number of hops. In the following example, the hop limit is set to 3. Note that when specifying a value for http-put-response-hop-limit, you must also set http-endpoint to enabled.

```
aws ec2 modify-instance-metadata-options \
--instance-id i-1234567898abcdef0 \
--http-put-response-hop-limit 3 \
--http-endpoint enabled
```

Enable the IPv6 endpoint for your instance

By default, the IPv6 endpoint is disabled. This is true even if you have launched an instance into an IPv6-only subnet. The IPv6 endpoint for the IMDS is only accessible on [Instances built on the Nitro System \(p. 218\)](#).

Currently only the AWS CLI and AWS SDKs support enabling the IPv6 endpoint for your instance.

To enable the IPv6 endpoint for your instance

Use the [modify-instance-metadata-options](#) CLI command and set the http-protocol-ipv6 parameter to enabled. Note that when specifying a value for http-protocol-ipv6, you must also set http-endpoint to enabled.

```
aws ec2 modify-instance-metadata-options \
--instance-id i-1234567898abcdef0 \
--http-protocol-ipv6 enabled \
--http-endpoint enabled
```

Turn on access to instance metadata

You can turn on access to instance metadata by enabling the HTTP endpoint of the IMDS on your instance, regardless of which version of the IMDS you are using. You can reverse this change at any time by disabling the HTTP endpoint.

Use one of the following methods to turn on access to instance metadata on an instance.

Console

To turn on access to instance metadata

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions, Instance settings, Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:
 - a. For **Instance metadata service**, select **Enable**.
 - b. Choose **Save**.

AWS CLI

To turn on access to instance metadata

Use the [modify-instance-metadata-options](#) CLI command and set the `http-endpoint` parameter to `enabled`.

```
aws ec2 modify-instance-metadata-options \
--instance-id i-1234567898abcdef0 \
--http-endpoint enabled
```

Turn off access to instance metadata

You can turn off access to instance metadata by disabling the HTTP endpoint of the IMDS on your instance, regardless of which version of the IMDS you are using. You can reverse this change at any time by enabling the HTTP endpoint.

Use one of the following methods to turn off access to instance metadata on an instance.

Console

To turn off access to instance metadata

1. Open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions, Instance settings, Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:
 - a. For **Instance metadata service**, clear **Enable**.
 - b. Choose **Save**.

AWS CLI

To turn off access to instance metadata

Use the [modify-instance-metadata-options](#) CLI command and set the `http-endpoint` parameter to `disabled`.

```
aws ec2 modify-instance-metadata-options \
--instance-id i-1234567898abcdef0 \
--http-endpoint disabled
```

Retrieve instance metadata

Because your instance metadata is available from your running instance, you do not need to use the Amazon EC2 console or the AWS CLI. This can be helpful when you're writing scripts to run from your instance. For example, you can access the local IP address of your instance from instance metadata to manage a connection to an external application.

Instance metadata is divided into categories. For a description of each instance metadata category, see [Instance metadata categories \(p. 887\)](#).

To view all categories of instance metadata from within a running instance, use the following IPv4 or IPv6 URIs.

IPv4

```
http://169.254.169.254/latest/meta-data/
```

IPv6

```
http://[fd00:ec2::254]/latest/meta-data/
```

The IP addresses are link-local addresses and are valid only from the instance. For more information, see [Link-local address](#) on Wikipedia.

Note

The examples in this section use the IPv4 address of the IMDS: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on [Instances built on the Nitro System \(p. 218\)](#).

The command format is different, depending on whether you use IMDSv1 or IMDSv2. By default, you can use both versions of the IMDS. To require the use of IMDSv2, see [Use IMDSv2 \(p. 863\)](#).

You can use PowerShell cmdlets to retrieve the URI. For example, if you are running version 3.0 or later of PowerShell, use the following cmdlet.

IMDSv2

```
PS C:\> [string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
PS C:\> Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} -Method GET -Uri http://169.254.169.254/latest/meta-data/
```

IMDSv1

```
PS C:\> Invoke-RestMethod -uri http://169.254.169.254/latest/meta-data/
```

If you don't want to use PowerShell, you can install a third-party tool such as GNU Wget or cURL.

Important

If you install a third-party tool on a Windows instance, ensure that you read the accompanying documentation carefully, as the method of calling the HTTP and the output format might be different from what is documented here.

For the command to retrieve instance metadata from a Linux instance, see [Retrieve instance metadata](#) in the *Amazon EC2 User Guide for Windows Instances*.

Costs

You are not billed for HTTP requests used to retrieve instance metadata and user data.

Considerations

To avoid problems with instance metadata retrieval, consider the following:

- **In a container environment, we recommend setting the hop limit to 2.**

The AWS SDKs use IMDSv2 calls by default. If the IMDSv2 call receives no response, the SDK retries the call and, if still unsuccessful, uses IMDSv1. This can result in a delay, especially in a container environment. In a container environment, if the hop limit is 1, the IMDSv2 response does not return because going to the container is considered an additional network hop. To avoid the process of falling back to IMDSv1 and the resultant delay, in a container environment we recommend that you set the hop limit to 2. For more information, see [Configure the instance metadata options \(p. 868\)](#).

- **Create custom Windows AMIs using Sysprep.**

If you launch a Windows instance using a custom Windows AMI, to ensure that the IMDS works on the instance, the AMI must be a standardized image created [using Sysprep \(p. 154\)](#). Otherwise, the IMDS won't work.

- **For IMDSv2, you must use /latest/api/token when retrieving the token.**

Issuing PUT requests to any version-specific path, for example /2021-03-23/api/token, will result in the metadata service returning 403 Forbidden errors. This behavior is intended.

Responses and error messages

All instance metadata is returned as text (HTTP content type text/plain).

A request for a specific metadata resource returns the appropriate value, or a 404 - Not Found HTTP error code if the resource is not available.

A request for a general metadata resource (the URI ends with a /) returns a list of available resources, or a 404 - Not Found HTTP error code if there is no such resource. The list items are on separate lines, terminated by line feeds (ASCII 10).

For requests made using Instance Metadata Service Version 2, the following HTTP error codes can be returned:

- 400 - Missing or Invalid Parameters – The PUT request is not valid.
- 401 - Unauthorized – The GET request uses an invalid token. The recommended action is to generate a new token.
- 403 - Forbidden – The request is not allowed or the IMDS is turned off.

Examples of retrieving instance metadata

The following examples provide commands that you can use on a Windows instance. For the commands to retrieve instance metadata from a Linux instance, see [Retrieve instance metadata](#) in the *Amazon EC2 User Guide for Windows Instances*.

Examples

- [Get the available versions of the instance metadata \(p. 878\)](#)
- [Get the top-level metadata items \(p. 879\)](#)
- [Get the list of available public keys \(p. 881\)](#)
- [Show the formats in which public key 0 is available \(p. 881\)](#)
- [Get public key 0 \(in the OpenSSH key format\) \(p. 881\)](#)
- [Get the subnet ID for an instance \(p. 882\)](#)
- [Get the instance tags for an instance \(p. 883\)](#)

Get the available versions of the instance metadata

This example gets the available versions of the instance metadata. Each version refers to an instance metadata build when new instance metadata categories were released. The instance metadata build versions do not correlate with the Amazon EC2 API versions. The earlier versions are available to you in case you have scripts that rely on the structure and information present in a previous version.

Note

To avoid having to update your code every time Amazon EC2 releases a new instance metadata build, we recommend that you use latest in the path, and not the version number. For example, use latest as follows:

```
curl http://169.254.169.254/latest/meta-data/ami-id
```

IMDSv2

```
PS C:\> [string]$token = Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token-ttl-seconds" = "21600"} -Method PUT -Uri http://169.254.169.254/latest/api/token
```

```
PS C:\> Invoke-RestMethod -Headers @{"X-aws-ec2-metadata-token" = $token} -Method GET -Uri http://169.254.169.254/
